With these facts in mind, the bureau organized regular weekly clinics in areas of approximately 50,000 population. To have attempted to serve too large a population in relation to professional time available would have resulted in the treatment service rapidly shifting into diagnosis. The areas chosen were, however, not fixed by geographical boundaries, as this would have raised questions of eligibility for the service based upon residence on one side or the other of an imaginary line. In most rural and semi-rural areas of approximately 50,000 population there is usually a larger or smaller town which serves as the functional center of the population. Shops, recreational facilities, and various community services are found there. Transportation facilities radiate therefrom. The weekly clinics were located at such points in the various areas chosen. Clients might choose which of adjacent centers was personally more convenient. The areas chosen were based on initial interest shown and lack of other comparable facilities within any reasonable distance. Experience has indicated that the majority of children came from a radius of 15 to 20 miles of the clinic center. However, in the past 6 years, 1,900 cases have come from 116 of the 169 towns in the state. This is not to say that the need of these 116 towns have been met. It merely means that only the most urgent cases have been brought to the clinic. Towns more remote from the clinic centers. Experience has shown that a psychiatric clinic for children operating on a 1 day

a week basis does, in fact, serve a population of roughly 50,000.

The measurement of the results of such a clinical program is impossible in the terms by which public health people usually measure progress in the prevention of disease. Until the various types of mental disorder are made reportable, and until preventive work is conducted on a much greater scale, any rates showing the effect of such work on the incidence of mental disease are meaningless. Hospitalization rates are affected by too many other and more heavily weighted variables to give any satisfactory answer. Those working with individual cases can make subjective estimates of improvement in the cases seen. These estimates indicate from 60 to 70 per cent of the cases improved. It must be remembered, however, that, though the clinics are operated on a treatment basis, many cases are sent in for diagnosis and recommendations only. This is especially true of dependent and neglected children coming before the court for commitment, to a certain extent for delinquent children, and largely for those crippled children where the orthopedic program to be undertaken hinges upon the psychiatric diagnosis. An indirect way of judging the results of the program is by the demand made by professional and lay organizations for an extension of the service. The amount of such demands, if they could be satisfied by the bureau, would necessitate about five times the present staff.

The bureau has made one attempt to measure the results of its clinical work. A study was undertaken to see what if any savings were effected as a result of the clinical program. All cases during a particular year were reviewed with the idea of determining those for whom institutionalization would have been necessary except for the work of the bureau. During the year chosen, 477 children were seen for diagnosis and treatment. Sixty-six cases were found in

which there was practically no doubt as to probable institutionalization. Commitment proceedings had already been started on 29, plans for commitment had been made by family or agency on 19, and, of the remaining 18, it was the unanimous opinion of the staff that they would have had to go to various institutions. The particular institutions to which these children would have gone was determined, the per capita costs of these institutions obtained, and the average length of stay of patients in the various institutions ascertained. The total probable cost of hospitalizing these 66 cases was then estimated at just short of \$200,000. The expenditure of the bureau for the year was \$28,641.25. If the cost of institutionalization of the children for just this particular year is estimated, it comes to \$43,294. No effort was made to estimate the costs of the other 411 children who presented various behavior, personality, or educational problems, though the greatest number of improved cases belonged in this group.

The educational work of the bureau has been conducted as a part of the general program of public health instruction. In all lectures, articles, and radio talks, the point of view of the psychobiological nature of the individual has been stressed. This orientation fits in easily with any specific health instruction pertaining to the care of the structural aspects of the individual. For professional groups dealing with children, lecture courses have been given which would assist them in their handling of behavior and personality problems. The bureau also distributes a large number of pamphlets. One of these, published by the bureau, has been sold in considerable quantities outside of the state and nation during the past 12 years.

The professional staff of the bureau engages in a variety of activities which may be classified as participation in com-

munity activities. Considerable work is done on various committees, and in many instances this may be of more far-reaching significance than the treatment of any specific case. It is particularly important that when general policies are being established which affect the lives of large numbers of children, the effect of these policies on mental health should be considered. Participation in various professional meetings might be considered a part of the educational program. Various state departments call upon the bureau for advice. The bureau, as a matter of practical necessity, serves as a clearinghouse for all sorts of individual inquiries regarding mental disease, facilities for treatment, legal procedures involved in the care of mental patients, and a host of other services.

In 1935 the General Assembly passed an act requiring that the private mental hospitals obtain a license from the Connecticut State Department of Health, and directing the Public Health Council to establish a sanitary code for their regulation. The duty of inspecting the hospitals and seeing that the regulations were carried out became the responsibility of the Bureau of Mental Hygiene. There are 16 private mental hospitals with approximately 1,200 beds. As a result of this activity, there has been considerable improvement in the plant, general sanitation, and in the medical and nursing care of these institutions. The matter of fire hazard was one of the most urgent problems at the beginning, but all the hospitals very shortly met fire regulations. A very few unsatisfactory hospitals have been eliminated. Various complaints about the hospitals are made from time to time. These are all investigated by the bureau and, where the complaints are warranted, remedial measures initiated.

Since January, 1941, the bureau, like so many organizations, has taken on new duties and responsibilities in con-

nection with national defense. At the request of the Medical Director of the State Selective Service, the bureau set up machinery for checking the names of registrants against various state files where there might be evidence of previous neuropsychiatric disability. Through the coöperation of various state departments and the state hospitals, this central checking process in the bureau was possible.

As of August 1, 1941, some 24,000 names have been checked and 3 per cent of these have been forwarded to the State Selective Service Office for deferment or other disposition. During this period, the director of the bureau has acted as chairman of an advisory psychiatric committee to the Medical Director of Selective Service. This committee has helped to work out procedures for more and better psychiatric examinations of registrants, has initiated an experiment in large scale psychiatric examinations, and planned a section of

the annual meeting of the State Medical Society for local board examiners.

During the recent session of the General Assembly, a State Defense Council was created. Since June, 1941, the director of the bureau has served as a member of the Welfare and Community Activities Committee of the Council. Tentative plans of the Medical Committee of the Council are that, in the event of evacuation of children, the bureau would be responsible for the organization of the psychiatric services needed for an expected 10 or 15 per cent of emotionally disturbed children.

This, then, is a brief summary of the major activities of the Bureau of Mental Hygiene of the Connecticut State Department of Health. The clinical service is the activity requiring the largest amount of professional time. The needs of the state for this service are not yet nearly met. This, we believe, can only be done through the addition of new clinical units.

The Expanded Rôle of the Sanitarian^{*†}

H. A. KROEZE, C.E., F.A.P.H.A.

*Director, Division of Public Health Engineering, State Board of Health,
Jackson, Miss.*

IN the field of environmental sanitation in the local health program our concepts of service have undergone a remarkable change in recent years. Our increasing knowledge of the etiology of disease and control of morbid conditions has called for changes of methods and a shifting of emphasis, activities, personnel, and point of view. The attitude of the people in this country toward the responsibility of the government—federal, state, and local—in public health is crystallizing toward a more rational widespread public health program. While it is clear that there is this steadily increasing demand on the part of the public for a more comprehensive program, there is likewise developing a demand for an improvement in the quality of the services rendered. Such factors are having a tremendous influence on the development of the sanitation program and call for an understanding of the rôle the sanitarian shall play in the expanding program of local health service.

In a discussion of the rôle and qualifications of sanitation personnel in the local health program there is generally a divergence of views. It appears that these discussions take two trends; that is; there are those who approach the problem from the theoretical and academic standpoint and those who look

at it from an intensely practical viewpoint. Those who look at this problem from the practical standpoint consider there is a need for the services of the sanitarian in local health service, and where adequate, intelligent, technical administration and supervision are provided either locally or through district or state sources, the rôle and usefulness of such personnel are expanding. Those who feel that only personnel with public health engineering training have a place in the sanitation program of local health departments are inclined to be too theoretical and lose sight of many existing factors which make such a conclusion impracticable, unnecessary, and perhaps unwise.

In considering the utilization of the sanitarian it appears that three conditions are vitally necessary to insure the proper expansion of the sanitation program of the local health department to furnish the technical services our present knowledge will permit and to meet the demands of the public for the type and quality of services they have reason to expect. These conditions are: (1) a clear understanding of the nature and scope of environmental sanitation; (2) a realization of the responsibility for the technical administration and supervision of the sanitation program; and (3) a proper coördination of the services rendered by various types of personnel.

Engineering may be broadly defined as the utilization of materials and forces of nature for the benefit of man. The employment of these materials and

* Read before the Southern Branch American Public Health Association at the Tenth Annual Meeting in St. Louis, Mo., November 11, 1941.

† The use of the term "sanitarian" in this paper is intended to apply to sanitation personnel of the essentially local rural health services who do not have public health engineering training and experience.

forces in the adjustment of the environment to man primarily for the protection and promotion of public health has developed into a specialized branch of engineering termed "public health engineering." This branch of engineering, "includes the public health aspects of all types of environmental conditions whose control is based upon engineering principles regardless of the magnitude or technical difficulty of the individual problems involved."¹ The recognition, therefore, "that environmental sanitation problems—whether small or large, simple or complicated—are fundamentally engineering in character"¹ leads to the conclusion that the nature and scope of environmental sanitation requires engineering training in the solution of the problems involved regardless of the qualifications of the personnel who render sanitation services in the field.

In the technical administration of the sanitation program in the local health department it is felt there is not yet as clear a realization by the public health engineer of his responsibility thereto as is his feeling that the problems involved in sanitation are of a public health engineering nature. Furthermore, many health officers do not appreciate the need for engineering training as a prerequisite to proper planning and supervision of sanitation programs. Obviously, unless those in administrative positions realize their responsibility in providing proper technical supervision of these activities the task will be performed by others, presumably less qualified by education and training. Under such conditions those engaged in local sanitation service, whether inexperienced public health engineers or sanitarians, must develop policies and procedures without benefit of the guidance of experienced public health engineers. In discussing the apparent failure of sanitarians in a certain state, an able public health

administrator recently stated in a private communication: "I would naturally expect them (the sanitarians) to fail in that state for the lack of intelligent leadership in the state health department. My experience has demonstrated thoroughly to me that, where a state had an excellent division of public health engineering with constructive leadership interested in improving environmental sanitation, sanitarians had played a most important and necessary rôle." Much confusion now existing in both the administration and performance of the local sanitation program could be eliminated if a proper realization of professional supervision could be established.

In most successful organizations there is a clear understanding of the particular functions of the various persons making up each organization. In each case persons are assigned responsibilities commensurate with their basic training and ability, all performing their allotted tasks under the technical guidance and general supervision of basically qualified individuals. For reasons of economy and efficiency any professional organization must supplement the services of its basically qualified workers by assigning specific functions to sub-professional workers who through training and experience have demonstrated ability to perform such functions efficiently under adequate supervision. Such persons obviously should not be assigned tasks which depend upon professional knowledge and experience they do not possess. Since such procedures find ample justification in various fields of medical and engineering endeavor, are not the same principles applicable to the proper functioning of a local sanitation program? Is it not possible, therefore, for the sanitarian with proper educational qualifications, basic training, and experience to perform specific assignments in the local health program

under specified procedures and adequate professional supervision? If the answer to these questions is in the affirmative, it appears evident that the rôle of the sanitarian has been and will be further expanded.

In trying to determine the degree to which personnel with professional qualifications should be employed for local health service, one is confronted with a number of practical phases of the problem which must be considered. The type and kind of public health engineering problems encountered in the average rural county in the South frequently are not of sufficient magnitude to require individual or independent solution. In such areas a public health engineer is not long satisfied performing chiefly routine services. Also, in these cases, budgetary limitations too often mitigate against the employment of such personnel who would remain for a sufficient length of time to develop a program of full value. Frequent shifting of personnel is not conducive to real accomplishments nor will the public give its best support to the health department which has a constantly changing group of workers. These are considerations which are vitally important in the program of local health service and have a direct bearing on the use of the sanitarian in this service in many areas throughout the South which are predominantly rural.

The recent use of Social Security funds to make available training courses for sanitarians has had a real influence on the quality of persons seeking employment in environmental sanitation. This, together with more rigid qualifications applying to persons seeking entry into this field, has elevated the sanitarian's position to a more useful one than formerly and has expanded his opportunities for service.

The sanitarian's rôle is being further expanded through the broader program

of local sanitation work resulting from better coverage of previously recognized problems and also the appearance of new problems. Examples are the more intensive programs of school sanitation, of food control, and the relatively recent problem of typhus fever control. The type and quality of sanitation service rendered by the progressive local health department today bears but little resemblance to that of a decade or two ago.

There is a growing realization on the part of engineers of state health departments of their responsibility for the proper guidance and supervision of the local sanitation program. This tends toward a broader program in this field and also makes it possible for the local sanitarian to assist with certain difficult and technical activities which formerly have been reserved for state handling. This provision of better technical guidance and supervision is expanding the usefulness of the sanitarian and makes it possible for the local health department to render a more adequate sanitation service to the public than formerly.

With the improvement of the quality of sanitation services there are indications of an increasing interest on the part of the health officer in the duties and responsibilities of the sanitarian. This increasing interest is having its influence on a closer coördination of the activities of the various personnel of the health department which in turn enables the sanitarian further to extend his usefulness.

The progress made in public health work in recent years has greatly expanded the program of the well organized local health department and has demonstrated the value and importance of the sanitarian's activities. This expansion calls for more technical services from the state health department and has clearly shown the need of adequate and integrated supervision. Where

this supervision is not being adequately supplied, the local sanitation program suffers and the sanitarian himself, without this leadership, cannot be as effective in his efforts.

While the sanitation program has been broadening, there has not been, in many cases, a corresponding increase in personnel adequately to handle the work to be done. A deficiency of personnel results in too much superficial effort, spreads services so thin that supervision cannot be efficient, and decidedly limits the effectiveness of the sanitarian. Many failures to produce quality accomplishments in sanitation are due to a lack of sufficient personnel regardless of improvement in the qualifications, energy, and enthusiasm of those involved. The rôle of the sanitarian would be greatly enhanced and the services he is supposed to render would be of much better quality if a more rational method were universally used in determining the number of such personnel required adequately to serve a given population or size and kind of area.

Though there are still many inadequacies in the sanitation service being rendered in different areas of the country, there have been many improvements in the quality of personnel engaged in this endeavor; improvements in technical supervision being rendered to local health services; a broadening of the sanitation program, and correspondingly a greater opportunity for the competent sanitarian to display his rôle of usefulness. There is a constantly increasing interest and demand on the part of the public in regard to improved environmental sanitation, and an apparent, greater interest on the part of the health officer in the rôle the sanitarian should play in the entire public health program. These conditions seem to indicate an expanding rôle for the sanitarian in the type of health program being generally developed in the rural areas throughout the South.

Use of Alum-Treated Pertussis Vaccine, and of Alum-Precipitated Combined Pertussis Vaccine and Diphtheria Toxoid, for Active Immunization*

PEARL L. KENDRICK, Sc.D., F.A.P.H.A.

With Statistical Analyses by E. S. Weiss†

Michigan Department of Health Laboratories,‡ Western Michigan Division, Grand Rapids, Mich.

THE study of active immunization against pertussis, in Grand Rapids, Mich., has been the subject of several reports.^{1, 2, 3} Field Series I, comprising 4,212 children, was the subject of a paper read at the meeting of the American Public Health Association in Kansas City, 1938. The total quantity of vaccine was 70 billion organisms given in four weekly subcutaneous doses of 1, 1.5, 1.5, and 3 ml. respectively, the last amount given in two bilateral injections. The pertussis incidence in the vaccinated group was 2.3 per 100 person-years, in comparison with 15.1 among the unvaccinated controls. The secondary attack rates³ were calculated for all the susceptible children in the families in which pertussis occurred and found to be 36.4 in the vaccinated group in comparison with 92.0 in the

unvaccinated group, in the age band 1 to 6, inclusive. An indication of what has happened in the series since it was closed for compilation of records in November, 1937, is found in an analysis of pertussis cases reported to the Grand Rapids Health Department. A tabulation of these reported cases was made from the beginning of the study in 1934 through December, 1940, and compared with those cases discovered in the field study. The results are shown in Table 1.

Of 2,074 cases of pertussis reported to the City Health Department during the period of study, 181 were found among the study children of Series I; 8 in the vaccine group, and 173 among the unvaccinated controls. From the close of the study through December 31, 1940, there were 1,353 cases reported to the Health Department of which 117 were found among the study children; 10 in the vaccinated group, and 107 in the control group. The relatively larger difference in the ratio of cases in the test and control groups, when based on those reported than when determined by the field study analysis, is easily explained by the case histories available in the study records. In general, only the clinically typical

† Assistance in carrying out this investigation has been provided by the Public Health Project of the Michigan Work Projects Administration, Official Project No. 165-1-51-356. E. S. Weiss is State Supervisor of the Michigan Public Health Project.

The study received a grant of Maternal and Child Health funds from the Michigan Department of Health.

‡ In coöperation with the City Health Department of Grand Rapids, Mich., Dr. C. C. Slemons, Health Officer.

TABLE 1

Field Series I. Pertussis Cases Among the Children of Study Series I, Which Were Reported to the City Health Department

<i>Found and Reported Cases of Pertussis</i>	<i>Study Period: Mar. 1, 1934, Through Oct. 31, 1937</i>				<i>After Study: Nov. 1, 1937, Through Dec. 31, 1940</i>			
	<i>Control Group</i>	<i>Vaccine Group</i>	<i>Total</i>	<i>C/V Ratio</i>	<i>Control Group</i>	<i>Vaccine Group</i>	<i>Total</i>	<i>C/V Ratio</i>
Found by regular visiting in study Series I	348	52	400	6.7	Study series terminated			
Reported to City Health Dept. among children of Series I	175	8	181	21.6				
Total reported cases for whole city during same period	2,074	107	19	117	10.7
							1,353

cases were reported, the milder ones were not.

After completion of Field Series I, which gave good evidence of an immunizing antigen in the vaccine used, it seemed logical to investigate certain problems related to the type of vaccine and dosage schedule from the standpoint both of protection and practicability. In Field Series II, the object was twofold: first, to test the efficacy

of a smaller quantity of vaccine than that used in Series I but given over a longer period of time; and second, to test an alum-precipitated vaccine preliminary to its combined use with diphtheria toxoid in a study of simultaneous immunization against pertussis and diphtheria. In Field Series III, the use of alum-precipitated, combined pertussis vaccine and diphtheria toxoid is being investigated.

FIELD SERIES II. ALUM-PRECIPITATED COMPARED WITH "STANDARD" PERTUSSIS VACCINE AS AN ACTIVE IMMUNIZING AGENT

GENERAL PLAN OF INVESTIGATION

The study area, the method of entry and withdrawal of test and control children, the plan for obtaining follow-up information, and the system of records, were all essentially as described for Field Series I.²

Selection of test and control groups—

The age group under study was defined as including from 6 months up to but not including the 3rd birthday. The children were presumably susceptible, that is, with a record of neither previous vaccination against pertussis nor an attack of the disease.

As in the first field series, the vaccinated group was made up of children who were brought to the city immunization clinic for pertussis vaccination. The receiving nurse designated the en-

try history blanks alternately for alum and standard vaccine, and the injected children were entered as of the date of last injection. The control children, as in Series I, were designated at random from the city department of health immunization file of preschool children. After the information blanks were received from the clinic for a group of children who had completed their immunization, an approximately equal number of children, within the age group of the study and in the same districts as the injected children, were called on by the nurses for verification of their histories and suitability for inclusion in the study. These children if found to be presumably susceptible were entered as controls as of the date designated. There were only 40 col-

TABLE 2

Field Series II. Number of Children and Average Experience in Months, According to Reason for Withdrawal from Study

Reasons for Withdrawal	Number of Children				Average Experience in Months			
	All Groups	Vaccine Groups		Control Group	All Groups	Vaccine Groups		Control Group
		Alum	Standard			Alum	Standard

* Includes 4 deaths from other causes in the control group, and 2 deaths in each of the other groups.

ored children in the whole series and they are tabulated along with the others.

Period of observation—The study period for the series extended from January 1, 1938, through December, 1940. The period of observation for any particular child was the number of months from entry to withdrawal. A record was terminated for any of the following reasons: attack of pertussis; moved out of study area; vaccination of control; death; a few miscellaneous reasons, such as lack of coöperation; and, finally, close of study December 31, 1940, for compilation of records and analysis. The numbers of children withdrawn for various reasons in the vaccinated and control groups, and the average experience per child in each group, are shown in Table 2.

Comparison of vaccinated and control groups—It is well recognized as pointed out by Bell⁵ that it is impossible to

select identical study groups, and that, even if it were possible to make all attributes identical at the moment of selection, they would not remain so. An effort was made, however, as previously described, to obtain reasonably comparable groups by designating in the control group presumably susceptible children of the same age and geographical distribution as the vaccinated children. In Table 3 a comparison is given of several factors which seem to have some obvious relation to comparability between groups.

The standard vaccine and control groups are seen to be approximately the same size. The alum vaccine group, according to method of choosing children for vaccination, should be the same as the standard. The reason for its smaller size is to be found largely in the shortage of alum vaccine supply at one period in the study, at which time the injections were continued with

TABLE 3

Field Series II. Comparison of Vaccine and Control Groups with Respect to Factors Related to Selection

	All Groups	Vaccine Groups		Control Group
		Alum	Standard	
(a) Number of children	2,751	655	993	1,103
(b) Mean length of experience in months	16.0	18.6	16.1	14.4
(c) Mean age at entry in months	14.0	13.7	13.8	14.4
(d) Males per 100 females	111	107	114	111
(e) Average interval between nursing visits	2.7	2.7	2.8	2.6
(f) Per cent attacked by measles, scarlet fever, and chicken pox	8.1	6.4	8.1	9.1
(g) Upper respiratory infections other than pertussis, per 100 person-years	42.8	45.9	42.0	41.4

standard vaccine. The records of children who received both types of vaccine were eliminated from the analysis.

The somewhat shorter average experience of the control children in comparison with vaccinated children is explained by the withdrawal of many because of pertussis vaccination. There is no real difference in the mean age of the groups, in the sex ratio, or in the average interval between nursing visits. Finally, the incidence of scarlet fever, measles, and chicken pox, as well as the relative frequency of upper respiratory infections other than pertussis, indicates that the opportunity for exposure to some of the common childhood diseases was approximately the same in the vaccinated and control groups. The differences are within the limits of sampling variation.

A comparison of the number of three-person families, that is, of families in which it may be assumed there is only one child, suggests some difference between the vaccinated and control groups. Of the families with vaccinated children, 47 per cent were three-person families in comparison with 20 per cent of the families of the control children.

VACCINE USED *

"Standard" pertussis vaccine—The term "standard" vaccine is applied to the type of product used in Series I,² since the results obtained with it form the basis for comparison with the results of subsequent study series. This vaccine was a 10 billion per ml. suspension in saline of *Hemophilus pertussis* organisms with smooth characteristics, as indicated by tests just previous to their use. The killing agent was merthiolate.

Alum-precipitated vaccine—A suspen-

sion of *Hemophilus pertussis* was prepared just as for the standard vaccine used in Series I.² It was then precipitated with alum, essentially as described by Harrison, Franklin, and Bell,⁴ and by Bell,⁵ by the addition of 1 per cent potassium alum in the presence of 0.27 per cent sodium bicarbonate.

A point worthy of comment is the ease and speed with which the precipitated vaccine shakes into a homogeneous suspension.

Dosage schedule—A total of 3 ml. of vaccine was given in 3 subcutaneous injections of 1 ml. each, alternately in the two arms, with an interval of 1 week between the first and second, and an interval of 4 weeks between the second and third injections.

Immediate reactions to the injections—The immediate reactions after injection of the standard vaccine in this series were of no consequence. In general, there was a slight local reaction, with the formation of subcutaneous nodules which often persisted for several weeks. Following the injection of alum vaccine, the subcutaneous nodules were a little more marked. In one instance, a sterile abscess occurred. Bell⁵ observed that such a reaction may be associated with a too superficial injection.

DEFINITIONS WITH RESPECT TO DIAGNOSIS, SEVERITY OF ATTACK, AND EXPOSURE

The same definitions were used for Series II as for Series I. Primarily, the diagnosis of pertussis in study children and in source cases was based upon a detailed case history taken by the nurse. All available supplementary information was used in making the final decision, such as the judgment of the attending physician or members of the health department, cough plate findings, and records of exposure. An attack was considered *moderate* if the child had characteristic whooping and

* The vaccine was prepared in the Biologic Products Division of the Michigan Department of Health Laboratories. J. T. Tripp, Associate Director.

vomiting, an uncomplicated disease duration of approximately 4 to 6 weeks, and no evidence of marked interference with nutrition. In a *severe* attack the paroxysms of coughing and whooping were unusually severe and frequent, there was marked loss in weight or complications such as bronchopneumonia or prolonged bronchitis. The *mild* attack had only occasional whooping or vomiting, no obvious interference with nutrition, and usually lasted no more than 4 weeks. Under *very mild* attacks were included coughs of not more than 3 weeks' duration in which characteristic symptoms were absent and the diagnosis depended upon either a record of definite exposure or positive cough plate findings. The average interval between onset of attack and the first visit for obtaining the history was 1.8 months. Over 82 per cent of the histories were secured within 2½ months after onset of first symptoms.

Exposures in this report are tabulated as occurring in own household or outside of own household; that is, familial and community exposures, respectively. Each recorded exposure is based upon exposure to a source case in which the diagnosis was established on the basis of a written case history and under the same criteria used for the attacks among the study children. Exposure must have occurred within 3 weeks of the onset date of the source case, and a particular attack was related to a source case only if it occurred within an arbitrarily designated period of 30 days after onset of the source

case; that is, the onset date of the attack must be within 51 days of the onset of the source case.

RESULTS OF FIELD SERIES II

Pertussis incidence in vaccinated and control groups—In Table 4 is shown the pertussis incidence in terms of attacks per 100 person-years for alum and standard vaccine groups, and control groups.

Of the total 158 pertussis attacks which occurred in the whole series, 1.6, 1.8, and 9.0 attacks per 100 person-years occurred in alum, standard, and control groups, respectively.

In comparing each of the vaccinated groups with the control group, the difference obviously is significant. Comparing the two vaccinated groups, the difference is not significant.

Comparison of incidence in Field Series II with incidence in Series I—While it is not possible to compare directly the incidence in Series II with the previously reported Series I, it seems possible to make a reasonable comparison through the medium of the control groups. The attacks per 100 person-years in the control groups of Series I and II were 15.1 and 9.0, respectively. If it can be assumed that these rates give a fair indication of normal expectancy within the study groups, the expected incidence in the vaccinated groups of Series II, if the results were similar to those of Series I, can be derived by a simple proportion, since the incidence in the vaccine group in Series I is known to be 2.3. By this

	No.	Per cent	Alum		Standard		No.	Per cent
All attacks	158	100	16	100	23	100	119	100
Very mild	24	15	7	44	7	31	10	8
Mild	47	30	9	56	9	39	29	24
Moderate	71	45	6	26	65	55
Severe	16	10	1	4	15	13

means, the expected number of attacks per 100 person-years in the vaccinated group is calculated to be 1.4. The actual incidence in the alum group was 1.6 and in the standard group, 1.8. In relation to the amount of experience, the difference between the expected and actual incidence is not significant with respect to either alum or standard group. This suggests that both the alum and standard vaccines in a total dosage of 30 billion organisms over a period of 5 weeks may be as effective as standard vaccine, 70 billion organisms, given over a period of 3 weeks.

Severity of attack—As pointed out repeatedly, the rating of the severity of pertussis is rough at best. Every effort was made to avoid bias and to use the same criteria, already outlined, for rating the attacks among vaccinated and control children. It was not possible, however, in many instances to avoid information on the part of the visiting nurse as to whether the patient had had vaccine injections. During the relatively frequent visits, such information was apt to be proffered by the mother.

As found also in Series I, the pertussis attacks in Series II were relatively milder in the vaccinated than in the control children. This is shown in Table 5.

The tabulation indicates further that there was a tendency toward even milder attacks in the alum group in comparison with the standard. It is

seen that 100 per cent of the attacks in the alum group were mild or very mild, in comparison with 70 per cent in the standard group and 32 per cent among the controls. A tabulation of severity and mean age gave no explanation of the difference in severity in the vaccinated and control groups. It is pointed out that the numbers of attacks in the vaccinated groups are small and the comparison therefore is considered only as suggestive.

Attacks of pertussis related to exposures—Exposure information was obtained in connection with the regularly scheduled nursing visits so that some of the exposures were recorded before the diagnosis of the attack which may have followed. Other exposures were recorded during the visits for obtaining the case histories on suspected attacks of pertussis.

There were no known exposures, that is; exposures sufficiently well defined to be accepted as such according to the definitions, among 2,751 of the children. Of the remaining 175 children with known recorded exposures, 50 were in the alum group, 52 in the standard, and 73 in the control group. Per hundred person-years experience there were 4.4 known recorded exposures among all vaccinated children and 5.5 among controls. A correlation of exposures with subsequent attacks is shown in Table 6.

Of the children without acceptable records of exposure, 1 per cent contracted pertussis in the alum group, 1

TABLE 6

Field Series II. Proportion of Children Attacked in Relation to Their Exposure Records

Record with Respect to Exposure	Alum Vaccine Group			Standard Vaccine Group			Control Group		
	Number of Children	Children Attacked		Number of Children	Children Attacked		Number of Children	Children Attacked	
		Number	Per cent		Number	Per cent		Number	Per cent
All records	655	16	2.4	993	23	2.3	1,103	119	10.8
No known exposures	605	5	0.8	941	8	0.9	1,028	52	5.1
All known exposures	50	11	22.0	52	15	28.8	73	65	89.0
Exposed in own household	17	7	41.2*	18	9	50.0*	54	53	98.1*
Exposed outside of own household	33	4	12.1	34	6	17.6	19	12	63.2

* Secondary attack rates.

per cent in the standard, and 5 per cent in the control group. Of the children with accepted records of exposure, 22 per cent in the alum group contracted pertussis, 29 per cent in the standard, and 89 per cent in the control group. Following exposure in own household, 41 per cent were attacked in the alum group, 50 per cent in the standard, and 98 per cent in the control group. The number of attacks is relatively small, and the larger percentage following exposure in the standard compared with the alum group is not significant.

Secondary attack rates—Since by definition all the susceptible children of a particular age band in the study families were entered in the study, the

secondary attack rates for the vaccinated and control groups are identical with the proportions of children attacked following exposure in their own households, just referred to in connection with Table 6.

SUMMARY OF RESULTS OF SERIES II

The data of Series II indicate protection of a large proportion of children injected with alum-precipitated pertussis vaccine in a total dosage of 30 billion organisms, given over a period of 5 weeks.

The results in no way contraindicate the use of alum vaccine, and form a basis for its trial in combination with diphtheria toxoid.

FIELD SERIES III. ALUM-PRECIPIATED COMBINED PERTUSSIS VACCINE AND DIPHTHERIA TOXOID FOR ACTIVE IMMUNIZATION

The use of several immunizing antigens simultaneously is not new. Even in the injection of a single strain vaccine we know we are introducing several separate antigens, and each will stimulate its own antibody. Experimentally in laboratory animals, many known antigens have been mixed for injection and each found to produce an individual antigenic stimulus. The most familiar example of mixed antigens for human immunization is triple

typhoid, paratyphoid A and B vaccine. Smallpox vaccine frequently is given at the time of last injection of diphtheria toxoid although not mixed with it. Recently, combined diphtheria and tetanus toxoid has been used, apparently with success.

With the multiplicity of accepted immunization procedures for children it is logical that appropriate combinations of antigens for active immunization be studied in order to reduce the number

of required injections, thereby lessening discomfort for the child and family, and simplifying administrative procedure. A number of workers have recognized that simultaneous immunization against diphtheria and pertussis would be a particularly desirable and reasonable procedure if its effectiveness could be demonstrated. Bordet,⁶ in 1936 announced that he and Ramon had plans for studying the use of such a product.

Since the findings of Series II in no way contraindicated the use of alum pertussis vaccine, it was considered safe and reasonable to test an alum-precipitated, combined pertussis vaccine and diphtheria toxoid. A study group was started January 1, 1940, in comparison with a standard vaccine group and a control group. These three groups comprise Field Series III, the subject of a previous preliminary report by the author,¹³ and of this interim report. Except for the substitution of alum-precipitated combined diphtheria toxoid and pertussis vaccine for the alum-precipitated pertussis vaccine, the methods of procedure were the same in all respects as for Series II.

THE COMBINED ANTIGENS *

Preparation of vaccine—*H. pertussis* cultures were grown and harvested as for standard vaccine, and the merthiolate-killed packed organisms suspended in crude diphtheria toxoid to make a final count of 10 billion organisms per ml. This mixture was precipitated by the addition of sterile potassium alum solution in amounts which ranged between 1.5 and 2.0 per cent. In each case, the exact amount of alum required for maximum precipitation was determined by preliminary titrations of aliquots with varying amounts of alum. The calculated amount of alum was

added to the bulk and the precipitate washed twice with saline, and brought back to the original volume with saline and the final product preserved with merthiolate 1:10,000.

The usual sterility, safety, and potency tests for diphtheria toxoid and for pertussis vaccine, respectively, were done before release of the product. Each ml. of the final antigen contained 10 billion *H. pertussis* organisms and the amount of diphtheria toxoid which on antigenic test would produce more than two units of antitoxin in guinea pigs.

Dosage schedule—Just as in Series II, three injections were given, with an interval of 1 week between the first and second injections and 4 weeks between the second and third. The first dose was 1 ml. of "standard" pertussis vaccine, and the second and third were each 1 ml. of the combined antigen. This provided the same dosage of pertussis vaccine as used for Series II, and the dosage of alum-precipitated diphtheria toxoid which is recommended by the Michigan Department of Health.

Immediate reactions—The immediate reactions, in general, resemble those which follow the injection of alum-precipitated pertussis vaccine or alum-precipitated diphtheria toxoid. Records on local and general reactions were obtained on more than 900 children by nurses' visits the day after injection, and further visits if indicated. Reactions were recorded as none, slight, moderate, or marked, according to a predesignated code. Marked local reactions were based upon an intensely sore area of 2 or more inches in diameter. A marked general reaction was defined to include such symptoms as vomiting, or high fever. As recorded, the majority of reactions were none or slight; only a few were marked. In three known instances, a sterile abscess occurred. Under Series II in this paper, reference has been made to the observation of Bell⁵ in this connection.

* The combined antigen was prepared by the Biologic Products Division, Michigan Department of Health. A separate communication will be made on the details of technic.

0.1 or more	122	82.4
0.2 or more	93	62.8
1.0 or more	22	14.9

IMMUNE RESPONSE OF THE INJECTED CHILDREN

Diphtheria antitoxin—As a criterion of antitoxic level, titrations * were done by the method of Fraser ⁷ in which mixtures of varying amounts of serum and constant amounts of toxin were tested for neutralization by skin injections in the rabbit. Tests were compared with controls on the same rabbit, in which

known amounts of antitoxin and toxin were used. Schick tests of the children prior to immunization have been avoided since they would complicate the interpretation of antigenic response to the combined antigen, due to the antigen in the Schick test material. Titrations have been made with the sera from 34 children before, and from 148 after injection of the combined antigen. The children were selected on the basis of ease of bleeding. The results are shown in Table 7, and cumulated in 7A.

* Diphtheria antitoxin titrations were made by the Biologic Products Division, Michigan Department of Health.

None of the children tested before immunization had as much as 0.001 unit of antitoxin and every one of those tested 5 to 20 months after immunization had at least that amount. As the tabulation indicates, 98.6 per cent of them had a level of 0.01 unit or more, and 82.4 per cent, a level of 0.1 or more. It is of interest to compare these levels with those obtained by Volk and Bunney⁸ in the Saginaw County, Mich., study. The determinations in both series were done in the same laboratory. In the age group from 2 to 5 years, 4 months after injection of two doses of alum-precipitated diphtheria toxoid, 97 per cent of the children had at least 0.01 unit, and 53 per cent at least 0.1 unit; at 12 months, the respective proportions at these two levels were 93 and 51 per cent. It should be pointed out that these authors were dealing with rural children, while the children in this study were largely urban. The results indicate that after injection with the combined antigen, the antitoxin reaches fully as high levels as after injection with an equivalent amount of alum-precipitated toxoid given alone.

Pertussis antibodies—As a criterion of response to the pertussis antigen the opsonocytophagic test as reported by Kendrick, Gibbs, and Sprick⁹ was used. In addition, some complement-fixation tests and agglutination tests were done. A total of 545 opsonic tests before and 311 tests after immunization are summarized in Table 8.

Of the opsonic reactions before immunization 99.3 per cent were negative or weak; 4½ to 14 months following immunization 79.7 per cent had reactions at least moderately strong, a reaction considered to indicate a significant antigenic response. Of these tests, 180 were on the same children before and after immunization, and the results were in line with those for the whole group, as recorded in Table 8.

Of 27 children tested by the complement-fixation method before injection, the reactions were negative in 26, and doubtful in 1. Six months to 1 year after immunization, 135 were tested; 105 were positive, 5 doubtful, and 15 negative.

Agglutination tests were done on 62 children from 6 to 15 months after completion of immunization and the titers were as follows: 5 were negative in 1:10 dilution; 9 had a titer of 1:10; 35 had titers 1:20 through 1:100; 13 had titers 1:250 or higher.

The results of the complement-fixation and agglutination tests indicate good response to the pertussis antigen.

INTERIM TABULATION OF RESULTS RELATED TO PROTECTION

During the period from the beginning of Series III on January 1, 1940, through September 30, 1941, the study series has come to include 2,194 children of whom 847 were injected with combined, and 380 with standard vaccine, and 967 were unvaccinated controls. The experience and incidence in

TABLE 8

Field Series III. Opsonocytophagic Tests with Pertussis Antigen Before and After Immunization with Combined Diphtheria Toxoid and Pertussis Vaccine

Time of Tests with Respect to Completion of Immunization	Number of Children	Per cent of Children with Opsonic Reaction	
		Negative to Weak	Moderately Strong or Strong
Before immunization	545	99.3	0.7
After immunization	311	20.3	79.7
4½ to 5½ months	38	13.2	86.8
6 to 8 months	179	20.7	79.3
11 to 14 months	94	22.3	77.7

NOTE: Of these tests, 180 were on the same children before and after immunization.

TABLE 9

Field Series III. Alum-Precipitated Combined Diphtheria Toxoid and Pertussis Vaccine: Interim Tabulation of Pertussis Incidence in Test and Control Groups

<i>Time at Risk and Attacks</i>	<i>All Groups</i>	<i>Vaccine Groups</i>		<i>Control Group</i>
		<i>Combined</i>	<i>Standard</i>	
Number of children	2,194	847	380	967
Person-years	1,536	610	386	540
Attacks	69	4	6	59
Attacks per 100 person-years	4.5	0.7	1.6	10.9

terms of attacks per 100 person-years are indicated in Table 9.

The children in this Series III are still under observation, additions are being made from week to week, and a final conclusion regarding protection is not being drawn. In this interim report, however, the incidence of 10.9 in the control group and of 1.6 in the standard vaccine group closely parallel the findings of 9.0 and 1.8, respectively, for Series II. Reason for particular encouragement is found in the low incidence of 0.7 for the combined vaccine group.

SUMMARY OF THE RESULTS OF SERIES III

Titration of diphtheria antitoxin levels before and after injection indicate as good response to the toxoid in the alum-precipitated, combined pertussis vaccine and diphtheria toxoid, as to diphtheria toxoid alone. Also, opsonocytaphagic as well as complement-fixation and agglutination tests, indicate that pertussis antibodies are stimulated by the pertussis vaccine.

An interim tabulation of incidence indicates 0.7 attack per 100 person-years in the combined vaccine group in comparison with 1.6 in the standard vaccine group, and 10.9 in the control group.

COMMENT

The question of dosage in relation to pertussis vaccination has received considerable discussion in various articles during the past several years. There is no experimental basis at pres-

ent for saying that one or another schedule is optimum. It can only be said that with a particular procedure, the results were as found. There has been a tendency on the part of some workers to increase the total dosage as an answer to incomplete protection in any study series, and heavier suspensions such as "double strength" vaccine are in use. The total amount undoubtedly is important, but investigations should cover more thoroughly the other phases of the problem: the type of vaccine, the number of injections and the period over which they are given, and the several questions associated with secondary stimulus. In view of inconclusive data as to the duration of immunity it would seem reasonable to study the advisability of re-immunization just before the child goes to school. Limited experience suggests that a single, relatively small injection may provide an adequate secondary stimulus.

In the study of *total dosage*, the desirability of giving no more than is required for a good degree of protection should be recognized. Investigations of the *type of vaccine* must take into consideration the possible value of toxic products of the pertussis organism as immunizing agents, in the light of the work of Evans¹⁰ and others. Also, the possibility should be explored further of *combining* the pertussis antigen with other antigens, such as diphtheria toxoid. On the subject of *interval* between injections, Faber,¹¹ Maclean,¹² and others, have called at-

tention to its possible importance. Bell,⁵ in his recent study of alum-precipitated pertussis vaccine used a 4 week interval between two injections. His results as well as those included in this paper suggest that the subject can be investigated further with profit. Field Series III in Grand Rapids, for which an interim report is made, is expected to throw more light on several phases of the problem as more experience is accumulated with a dosage schedule of 30 billion organisms given over a period of 5 weeks.

GENERAL SUMMARY AND CONCLUSIONS

The results indicate a good degree of protection against pertussis, following a dosage schedule of 30 billion organisms distributed in 3 injections over a period of 5 weeks. Also, the results appear similar to those in a previous series in which 70 billion organisms were injected over a period of 3 weeks. These observations suggest that the period over which the vaccine is administered should receive as much consideration as the total dosage.

Following the use of alum-precipitated, combined pertussis vaccine and diphtheria toxoid, good antigenic response to both the pertussis antigen and diphtheria toxoid was demonstrated by immunological tests. An interim tabulation on incidence indicates protection against pertussis following injection of the combined antigen.

A more definite conclusion on protection as well as on the question of an adequate dosage schedule awaits further observation.

ACKNOWLEDGMENT—The author is indebted to Dr. J. L. Lavan, former Health Officer of Grand Rapids, for his coöperation in the earlier part of the study; and to Dr. Grace Eldering for her assistance with various phases of the work. For the performance of opsonocytaphagic tests, the author is grateful to Dorothy Foster. The complement-fixation tests were done by Paul Fugazzotto as part of a more extended study on complement-fixation in pertussis, which will be the subject of a separate report. For work on agglutination, and general technical assistance, the author is indebted to Josephine Misner; and for assistance with the records, to Dorothy H. Maring. The constructive criticism of Dr. Kenneth F. Maxcy in the interpretation of the data is gratefully acknowledged.

Public Health as an Important Part of Pan American Defense*

DOMINGO F. RAMOS, M.D., F.A.P.H.A.

Minister of National Defense of Cuba, Havana, Cuba

IT would seem that there had almost been deliberate forethought in the selection as our meeting place of this beautiful spot called Atlantic City. Both its name and its geographical location bring to mind and to view the great ocean which is the most powerful ally in America's defense, and which at the same time links us with the English people across its waters who, in defending so valiantly their own liberties, serve as a strong bulwark in defense of our independence.

When we are attacked individually, we defend our own lives: individual survival is the basis of this defense. If our families are threatened, we rush to their defense and disregard our own safety; our survival loses its value for us if our families are in danger of being injured or destroyed.

When our country is in peril, we forget even our family duties; we bring or send our sons to the zones of greatest danger and abandon the rest of our families to their own resources. And why? Because, fellow citizens of the American Republics and of the democracies of the world, without liberty and independence for our countries, there is no possibility of happiness either for families or for individuals.

Today we have an even greater duty; we are called upon for an even greater patriotism—for us in the Americas, a continental patriotism, or

"American continentalism"; for all believers in democracy in the world, a common concept of liberalism, using the word in the sense of the defense of liberty. Without these qualities, continentalism and liberalism, which must be safeguarded at all cost, there is no possibility of decent living, whether for nations, families or individuals.

This great New World commonwealth of ours, this union of free peoples which here in America had its cradle and has its home, is the one which we must all of us defend, forgetting for the present all other interests, loyalties, and egotisms, so that we may the better preserve them for all time. The peoples of the Americas may have their differences in points of view and even in interests; the political parties of each of our countries may also hold varying opinions and follow different courses for the solution of their problems; the followers of each party and the citizens of each nation may evaluate in their own fashion the conduct of the public officials of their own countries, but today no citizen of any country, no partizan of any party, no party in any nation, and no nation on this continent, can have any other desire than to preserve the rights of liberty, political independence and voluntary confederation, based on the great principle of self-determination, which was won by our forefathers with such long and bloody sacrifice, and which we today enjoy as our inheri-

* Presented at a Special Session of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

tance. These rights are the foundations of our happiness and of the future of the world, and we Americans have the high duty of safeguarding them and of thus assuring the constant progress of civilization.

Nor can we differ in our decision to undergo the greatest sacrifices, to run the greatest risks, even to submit voluntarily to discipline at the temporary cost of our liberty of thought, speech, or action, in order to secure the coördinated and farsighted effort necessary for victory.

When the founders of our various countries proclaimed the rights of liberty which they had to defend by arms, their first act on enlisting in the liberating armies was to renounce all personal interest and ambition, however legitimate, and even their duties toward their families. Still more, they also renounced for the time being the very absolute liberty which they were defending, in order to permit the disciplined organization of the armies of their free peoples. The free peoples of America, in their democratic union of nations in a coöperative effort to defend liberty for their own sakes and for other peoples, must imitate those who, in proclaiming liberty and independence, knew how to adapt these same principles to discipline and interdependence during the struggle for freedom. The victory of democracy will come soon, and at less cost, if we delay no longer in creating an efficient, practical Pan American coöperation.

In the past, union made possible the beginnings of American liberty; the maintenance of unity created the American strength; the attainment of closer unity will successfully defend the liberty of America, and of the world.

As we offer the coöperation of public health to the defense of liberty, we do not forget that the victory of America in behalf of Cuban liberty permitted the consolidation of knowledge and

sanitary measures which have made possible the security of life and the advance of civilization and progress in the American tropics.

Recently the President of the United States, in a statement to the press on the four hundred and forty-ninth anniversary of the discovery of America, said, among other things:

Columbus acted according to the ideal of science. On the basis of assembled data, he arrived at a hypothesis; and he bent every effort to test his theory by actual experiment. The sighting of dim outlines of land in the distance, on the morning of the epochal twelfth of October, proved beyond contradiction his doctrine that dry land lay beyond the ocean; and he thereby opened new avenues of human history.

Neither Columbus nor any other man of science nor any statesman or colonizer could foresee the progress destined to be made by the lands discovered in the west. Nor can we of the present day foresee what further advances will be achieved in the coming years toward the goal of a world permanently at peace, permanently prosperous, permanently free. But we do know that the common striving of all of the countries of the Americas can be a powerful force in the interests of stability, peace, and freedom.

I quote these words of this eminent American statesman with the prediction that the last half century of the first half millenium of the discovery of America will see the culmination of this work in the scientific development which marks the bases of true civilization.

And that this may be so, two great conditions must be met: first, the triumph of liberty in the present world struggle; and second, the vision of a future based on science, but a future in which science is not exploited and falsified for the satisfaction of unhealthy ambitions, but, rather serves as a foundation for the political orientation of the world. And this vision must embrace not only the immediate future, but that which is yet far distant.

If we begin today to speed the fulfillment of the second condition, it will

greatly facilitate the attainment of our present aims.

As the result of new biological discoveries and the work of the organizations entrusted with their application in the conservation of health and the improvement of man, public health has become of extended importance and plays a greater rôle in the solution of the different problems of the individual, the family, the community, and the nation.

The American countries have been faced, and will be faced, with few problems which are equal in importance and urgency to that of defense.

It therefore seems logical that at a meeting of the American Public Health Association, which brings together health officers from all over the continent, we should discuss the manner in which all men dedicated to the national defense of each of their countries and to the joint defense of the Americas may coöperate.

It seems to me that the most important things for us to consider are: (a) the extension of public health work as part of the total defense in time of war, a function for which the term "biological" defense seems appropriate, as covering the different aspects included in our coöperation for defense; and (b) the means which must be employed to make this coöperation practical—the most important question.

In discussing the rôle of public health in defense, I shall omit the work of the medical and sanitary units attached to the armed forces, whose duties are to learn the biological efficiency of their personnel and to conserve and, where possible, to improve it.

The coöperation with which we are concerned forms the second line of this biological defense, and is closely tied up with the units which I have just mentioned, through its two great goals: the health of the individual and the healthfulness of the environment. We

have to be much more careful to prevent the development among the civil population of natural or artificially provoked illnesses which might spread to the army and naval forces, and we have to see that the limitations imposed by wartime economy have no repercussions in the causing of other illnesses or in the production of states of low vitality which will injure the "stock" of human power on which the nation must depend for military defense. In addition to this, we assure the training of physicians, so that they will not be lacking in our so-called "first line of defense"—that is so that they may be able to care for all the special needs of the armed forces.

What I have just said is, of course, known to everyone. The second question is how to proceed in order to attain our goals.

First we must remember that the battle is a battle of the whole hemisphere. We must, therefore, mobilize the Pan American Sanitary Bureau so that, while the danger exists, it may maintain an even closer coördinating connection with all the national departments of health and bring to them the best standardization of technics and disciplined coöperation.

We keep in mind that the military and naval forces have bases and will use in their operations certain roads which may be known before hand. Let us maintain the best possible sanitary conditions in the environs of bases and roads most likely to be used by the military forces.

We must also keep in mind the fact that these bases will be for the most part located in tropical zones, although some may be set up in temperate or even frigid regions. Therefore, our physicians and health officers, who may also find themselves at times working under the direction of the army or the navy, must receive special preparation for work in such regions.

We must realize that, just as the former war brought into use the so-called "chemical warfare," so, also, when the countries, now victorious, begin to face defeat the "biological war" of which so much has been said and written may be resorted to. If the armies or rather the commanders in the last war had foreseen chemical warfare, the latter would not have brought so much havoc. Let us be prepared, therefore, for a possible biological war.

The present war is characterized not only by the totality of the methods employed but by the necessity for the most precise coördination to maintain the unity of the whole. The whole civil, medical, and public health organization must stay in close coöperation

with the corresponding military and naval agencies. This is true both in the local national organizations as in the Pan American organizations when such are established.

This pleasant meeting in Atlantic City, where the representatives of all the departments of health of America are gathered with the American Public Health Association and the officers of the Pan American Sanitary Bureau permits me to suggest that the Pan American Sanitary Bureau and the United States Public Health Service study these problems, with the coöperation of the fellows and members of the American Public Health Association and of the sanitarians of the Americas whom they deem necessary and appropriate to this collaboration.

"MEN who are occupied in the restoration of health to other men, by joint exertion of skill and humanity are, above all, the great of the earth.

They even partake of the Divinity, since to preserve and renew is almost as noble as to create."

Voltaire

The Teacher of Hygiene and Public Health*

OLIVER E. BYRD, Ed.D.

*Associate Professor of Hygiene, Stanford University School of Health,
Stanford University, Calif.*

THOSE interested in the success of the health instruction program of the public schools are beginning to demand that hygiene shall be taught by able and well prepared teachers.

This quest for the qualified teacher is an eternal and most perplexing problem. It has practical consideration of the greatest importance for every generation of every century.

What criteria are teachers to use in judging their own capacities as health instructors? What standards are they to use in determining whether or not they have been truly effective in imparting health knowledge, shaping health attitudes, and influencing health habits? What guide is the school administrator to follow in selecting or assigning faculty members for the teaching of hygiene? What factors are health supervisors to have in mind when working for the improvement of instructional efforts on the part of teachers under their direction? These are all significant questions and we must come to grip with them sooner or later.

It is reasonable to say that health educators should have sound training in the fundamental sciences. It is intelligent to demand that they shall have an understanding of psychology and the philosophy and principles of educa-

tion. It is logical to conclude that health educators should have specialized training and experience in the field of health. It is also imperative to ask: does this preparation make a good teacher? Is it possible that a person can be qualified in these fundamental fields and still be an ineffective instructor? Does successful teaching result from careful preparation or is it a reflection of inborn capacities that must find expression? Does able teaching depend upon a few all-important characteristics or does it result from the interplay of a multitude of tangible and intangible qualities?

SOME NEGATIVE RELATIONSHIPS

It is sometimes just as important to divest the mind of misconception as it is to recognize the truth. A study of the research dealing with the prediction of teaching success mostly tells us what is *not* related to effective instruction.

1. *Intelligence does not have a significant relationship to success in teaching.* Most of the studies show a correlation between these two factors of less than .425 and some indicate a relationship of less than .1. In one important study there was a negative correlation of —.035 for high scores and of —.004 for median scores on intelligence tests.¹

The answer to this astonishing fact is not that intelligence is unrelated to successful teaching, but that teachers as a group are intelligent; hence this factor ceases to have value in discriminating

* Presented at the Annual Meeting of the Pacific Coast Division of the American Student Health Association at Stanford University, November 21, 1941.

between the good and the poor teachers. To put it another way, the minimal amount of intelligence needed for successful teaching is an essential requisite for getting through the teacher training institutions.

2. *Practice-teaching success and later field effectiveness have little in common.* An analysis of 15 investigations covering this point shows a correlation between these two factors of less than .36 in 14 of the studies.

It is difficult to explain this lack of significant relationship between practice-teaching success and later effectiveness in field teaching. On the surface it would appear that student performance in a classroom would be a most valuable criterion by which to judge future teaching success. Perhaps soft-hearted supervising teachers approve students who should not be allowed to qualify for teaching. Probably time and experience ripen the capacities of many who barely qualify in practice-teaching. It is likely, too, that some students with outstanding teaching ability are drawn into administrative or other positions that remove them from the classroom. Whatever the factors are that are in operation, they tend to destroy the value of the practice-teaching experience so far as prediction of ultimate teaching success is concerned.

3. *Scholarship in high school or college is not a good criterion for predicting teaching success.* Sandiford and others analyzed a number of studies of the factors involved in predicting teaching success and found that scholarship is not a dependable criterion.² With the exception of the findings of a single investigator the correlations between success in field teaching and high school grades ranged from .08 to .35. The correlation for single exception grades, with a range from .07 to .50. Statistical findings are a great deal of significance.

4. *There is a lack of correlation between teaching success and specialization in subject matter.* Odenweller found a correlation of only .281 between these two factors.¹ This study merely substantiates earlier findings. Dr. R. B. Montgomery of the University of Illinois has just completed a study of college hygiene courses and his conclusions are in keeping with earlier studies on this point.³ Dr. Montgomery says:

The physician and nurse are without doubt the best prepared in the subject matter but . . . the physician knows the least about educational procedures and, as a result, is often a poor teacher. Several colleges report that they were forced to replace the physician instructors with others. I believe there are three reasons for this: (1) the medical curriculum offers no place for courses in education and most physicians feel that they cannot afford the time to take them later; (2) most physicians mistakenly assume that their knowledge of the subject is sufficient to make them teachers; (3) almost all physicians do not think of their students as very callow youth just out of high school and find that it is difficult to adjust their own methods of thinking to the adolescent level . . . there are very, very few physician teachers.

SOME PROMISING LEADS
Research findings are not entirely negative. Odenweller made a study of 560 teachers in Cleveland on the assumption that if efficiency on the job is recognizable and measurable it is predictable.¹ The teachers in this study were ranked for effectiveness and personality by principals, assistants, and supervisors. Fellow teachers also ranked each other according to personality. A reasonably high correlation of .825 was found between personality and teaching effectiveness when both rankings were made by school administrators. When teachers in the same school building with the instructor being graded, there was a correlation of only .533 between teaching effectiveness as judged by administrators and personality as judged by these teachers.

While this study is not conclusive it reveals the fact that personality apparently has a closer relationship to teaching success than any other single factor that has yet been measured. We cannot attach too much importance to this conclusion because personality itself is a most intangible substance, assuming all forms with all individuals, and being very difficult to measure. Our common sense observations tell us, nevertheless, that some people do have a knack for getting along with others, for attracting others, and for leading others. We are apt to call this capacity personality and let it go at that, since we have learned from experience that personality is not confined to one channel or tabbed with a single label.

Several studies have been made in an attempt to evaluate teacher success from the standpoint of the pupil. Bryan analyzed the ratings of secondary school teachers by about 1,500 junior and senior high school students of New York City, and Cincinnati, Ohio.⁴ From this study it would appear that students consider a teacher a good teacher when he (1) explains his subject matter thoroughly; (2) knows his subject matter thoroughly; (3) works hard at his teaching; and (4) is sympathetic to his students.

Hart made a much larger study of student ratings of teachers when he analyzed the opinions of 10,000 high school seniors in 66 high schools in widely distributed parts of the country.⁵

In rank order, the 6 combinations of characteristics considered most typical of the best liked teachers were as follows:

1. Is helpful with school work, explains lessons and assignments clearly; uses examples in teaching.
2. Cheerful, happy, good-natured, sense of humor.
3. Human, friendly, companionable, one of us.
4. Interested in and understands pupils.

5. Makes work interesting, creates desire to work, makes class work a pleasure.

6. Strict, has control of class, commands respect.

On closer analysis these 6 points can be boiled down to 4, namely, (1) teaching skill, (2) personality, (3) interest in pupils, and (4) leadership ability.

It is difficult to state which of these factors is the most significant, but pupils always place a high premium on sympathy, patience, and understanding. It is the teacher who is most concerned about the welfare of his students who takes the pains to explain most clearly, and whose personality is allowed expression through service to these pupils. Such people have leadership ability because young people can recognize and follow those who are genuinely interested in their welfare.

John Frederick Boyes, the English essayist of the past century recognized the value of patience and sympathy in the educational process when he once stated:

If in instructing a child, you are vexed with it for want of adroitness, try if you have never tried before, to write with your left hand, and then remember that a child is all left hand.

IMPROVING HEALTH INSTRUCTION

The recognition of the personal qualities involved in good teaching is not the solution to the problem of securing better health instruction. It is only part of the solution.

There are two broad methods by which we can improve the quality of teaching in the field of hygiene. The first involves the selection and training of new teachers. The second calls for the improvement of teachers already in the field.

1. *The training of new teachers*—A most serious indictment can be made against most of our teacher training institutions in respect to the preparation of their students in the field of health. At a recent symposium Dr.

Deibert Oberteuffer of Ohio State made this statement⁶:

... the majority of American professional departments of education are either ignoring this responsibility, or are making well-meaning but futile and inadequate efforts to prepare their students in the appropriate aspects of health education.

The difficulty, however, originates largely in the faculties of the colleges of education. Two years ago, in a study made of professional preparation in physical education, a dean of education in a midwestern university was asked about the school health program in his state. He replied that it was poorly developed, mainly because the school administrators were slow to adopt it. Later he admitted that his school prepared most of those administrators and that rarely did one of these men, who were to become principals or superintendents, ever elect a single course in health education.

None of the courses in health education were required, nor had the thought of requiring such training ever penetrated the thoughts of this dean or his faculty. Also gained in the same study was the impression that of the college presidents, zoölogists, psychologists, sociologists, physiologists, and professors of education interviewed, the group who knew less about the health problem in school life and who cared least about corrective measures were the professors of education.

Even with proper selection and training of teachers in the field of hygiene we can expect at best but a slow infiltration of these new teachers who are qualified for superior instruction. First, because the number of new teachers each year constitutes no more than 10 per cent of the total teaching profession and, second, because the great majority of these new teachers are trained as specialists in other fields than hygiene; so that the number of beginning teachers who are well qualified in the subject matter of health education must be pitifully small. Third, even those teachers with specialized training and all of the personal qualifications for successful teaching, will not be assigned to the task of health instruction. Under our present educational organization we train our teachers as specialists, but

it is very likely that only a few will find themselves delegated to the teaching of the problems on which they are best qualified.

2. *The in-service training of health instructors*—There is great promise of improvement when our efforts are directed toward increasing the capacities and skills of teachers who have already been assigned responsibilities in health instruction—first, because the teachers in service greatly outnumber the new arrivals; second, because there will be much less wasted effort in terms of training people for one job and seeing them assigned to other work; and third, because such teachers are most receptive to any form of help that can be given them in solving problems in the field of their immediate responsibility.

A few teacher training institutions have begun to work actively with teachers already in the field. The tide, however, has not yet rolled in that direction. May I suggest that field service courses in which the instructor travels from school to school and from community to community will be commonplace tomorrow?

Such training is a natural follow-up of the earlier preparation that the teacher may have received from a given institution. When the professor of education goes into the classroom to give specific help to the teacher who is grappling with practical pupil difficulties, you can be certain that the quality of both the preliminary training by the schools of education and the classroom effort by the teacher will improve greatly. The next great step forward in the social science of education will come when our educational institutions offer this service.

The Search for Unity

"IF we are to have a durable peace after the war, if out of the wreckage of the present a new kind of coöperative life is to be built on a global scale, the part that science and advancing knowledge will play must not be overlooked. For although wars and economic rivalries may for longer or shorter periods isolate nations and split them up into separate units, the process is never complete because the intellectual life of the world, as far as science and learning are concerned, is definitely internationalized, and whether we wish it or not an indelible pattern of unity has been woven into the society of mankind.

"There is not an area of activity in which this cannot be illustrated. An American soldier wounded on a battlefield in the Far East owes his life to the Japanese scientist, Kitasato, who isolated the bacillus of tetanus. A Russian soldier saved by a blood transfusion is indebted to Landsteiner, an Austrian. A German soldier is shielded from typhoid fever with the help of a Russian, Metchnikoff. A Dutch marine in the East Indies is protected from malaria because of the experiments of an Italian, Grassi; while a British aviator in North Africa escapes death from surgical infection because a Frenchman, Pasteur, and a German, Koch, elaborated a new technique.

"In peace as in war we are all of us the beneficiaries of contributions to knowledge made by every nation in the world. Our children are guarded from diphtheria by what a Japanese and a

German did; they are protected from smallpox by an Englishman's work; they are saved from rabies because of a Frenchman; they are cured of pellagra through the researches of an Austrian. From birth to death they are surrounded by an invisible host—the spirits of men who never thought in terms of flags or boundary lines and who never served a lesser loyalty than the welfare of mankind. The best that every individual or group has produced anywhere in the world has always been available to serve the race of men, regardless of nation or color.

"What is true of the medical sciences is true of the other sciences. Whether it is mathematics or chemistry, whether it is bridges or automobiles or a new device for making cotton cloth or a cyclotron for studying atomic structure, ideas cannot be hedged in behind geographical barriers. Thought cannot be nationalized. The fundamental unity of civilization is the unity of its intellectual life.

"There is a real sense, therefore, in which the things that divide us are trivial as compared with the things that unite us. The foundations of a coöperative world have already been laid. It is not as if we were starting from the beginning. For at least three hundred years the process has been at work, until today the cornerstones of society are the common interests that relate to the welfare of all men everywhere."—from *The Rockefeller Foundation—A Review for 1941*—by Raymond B. Fosdick, President

Sensitivity to Coccidioidin Among Boys in an Eastern Preparatory School

JOSEPH D. ARONSON, M.D., AND J. ROSWELL GALLAGHER, M.D.

Office of Indian Affairs, Department of the Interior, Washington, D. C., and Henry Phipps Institute, University of Pennsylvania, Philadelphia, Pa.; School Physician, Phillips Academy, Andover, Mass.

TUBERCULOSIS surveys of school children frequently reveal a small but significant percentage of persons who fail to react to tuberculin of proven potency, but who show on roentgenological examination calcified nodules characteristic of healed pulmonary tuberculosis. When these findings occur it is usual for the physician to assume that the x-ray findings are indicative of tuberculosis and that the negative skin test indicates that the individual has lost his sensitivity to tuberculin or is anergic. However, recent studies^{1, 2, 3} suggest that in some instances the occurrence of a negative tuberculin test and roentgenologically demonstrable calcified pulmonary nodules could be explained by assuming that the x-ray findings represent infection with *Coccidioides immitis* rather than by the tubercle bacillus. Carter⁴ and Thorner³ have pointed out the similarity of the roentgen picture of coccidioidomycosis and primary pulmonary tuberculosis, and Cronkite and Lack¹ have described lesions similar to those of miliary tuberculosis in guinea pigs in which coccidioidomycosis was produced experimentally. A recent survey by Aronson, Saylor, and Parr⁵ among some Indians in Arizona has revealed that, in those areas where from 90 to

98 per cent reacted to the intracutaneous injection of coccidioidin, about 15 per cent of tuberculin-negative children had calcified pulmonary nodules, while in areas where such reactions were infrequent or absent, only an occasional calcified nodule was observed in tuberculin-negative cases. These results suggest that the lung findings following infection by *Coccidioides immitis* and those of healed tuberculosis cannot readily be distinguished roentgenologically from one another.

The studies of Gifford,⁶ Dickson,² Aronson, Saylor, and Parr,⁵ and Smith⁷ indicate that coccidioidomycosis may be more widespread than is generally appreciated, and stimulated us to make a survey of the students at an eastern preparatory school. All students are examined roentgenologically at the time of their initial medical examination, and all students showing suspicious or definite lesions of tuberculosis are reexamined annually or at more frequent intervals. The 680 students were tested with 0.01 mg. old tuberculin of known potency and, simultaneously, with 0.1 ml. of a 1:100 dilution of coccidioidin; those individuals negative to 0.01 mg. were subsequently tested with 1.0 mg. old tuberculin. The coccidioidin used in this study was prepared by Dr. Charles E. Smith of Stanford University by growing *Coccidioides immitis* on synthetic culture medium.

This study was aided by a grant from the Carnegie Corporation.

† i.e., calcified pulmonary nodules present

These students ranged in age from 13 to 19 years, 70 per cent being in the age group 16 to 17 years. Approximately 80 per cent resided in Massachusetts, New York, Connecticut, Pennsylvania, New Jersey, and Ohio, while the remaining 20 per cent represented 26 other states and 13 foreign countries. There were 10 students from Texas, 9 from California, 1 from Arizona, and 1 from New Mexico.

Of the students tested, 26 per cent were positive to 0.01 mg. of old tuberculin, and an additional 2.7 per cent were positive to 1.0 mg., while 17 individuals, or 2.5 per cent, reacted to 0.1 ml. of 1:100 dilution of coccidioidin. These figures are in sharp contrast to those of Thorner³ who tested 200 children in the Bakersfield, Calif., area and found that 30 per cent of the children in the 0-4 year age group and 40 per cent in the 15-19 age group reacted to coccidioidin, and to those of Aronson, Saylor, and Parr,⁵ who found that 89 per cent of 2,355 Indian children living in the southern part of Arizona reacted positively to 0.1 ml. of a 1:100 dilution of coccidioidin. The coccidioidin test

was repeated 3 months later with the same preparation of coccidioidin on the 17 students who reacted to the initial test. Similar reactions were obtained in 13 individuals, while in the remaining 4 cases the reaction was less marked than that observed on the initial test. Details of these tests, together with the data on each individual's age, tuberculin test, and chest x-rays are presented in Table 1.

After the coccidioidin test had been repeated, a questionnaire was sent to the parents of the 17 boys who reacted, and answers to the following questions were requested: (1) Has this boy always lived in the state in which he now resides? If not, in what other states has he resided? (2) Has he spent a week or more in any of the southwestern states? If so, in which states and approximately how long in each? (3) If he spent any time in any of these southwestern states, did he have any undiagnosed illness or any illness which was diagnosed as influenza while he was there? (4) Has he at any time in his life had an illness characterized by malaise, cough, fever, rash, joint pains and nodules over the extremities? Data from these questionnaires are presented in Table 2.

TABLE 2

Name	Residence	Ever in Southwestern United States	Any Illness in Southwestern United States	Never Any Illness Resembling Coccidioidomycosis
G.B.	New Jersey	No	—	No
A.B.	Ohio	No	—	No
W.D.	Kentucky	No	—	No
O.G.	Texas	Texas	No	No
D.H.	New York	No	—	No
F.K.	New York	No	—	No
J.K.	Maine	California— Several months	—	—
		Texas—1 week	Yes	"Glandular Fever"— California
		Nevada—1 week	—	No
N.L.	Missouri	Arizona	No	No
B.L.	Pennsylvania	No	—	No
C.M.	Ohio	Arizona (9 mos.)	No	No
J.M.	Maryland	No	—	No
H.R.	Connecticut	Arizona (2 wks.) California (2 wks.)	No	"Grippe"—Montana
J.S.	Missouri	New Mexico (2 wks.)	—	—
		Arizona (6 wks.)	No	No
L.S.	Connecticut	Arizona (5 mos.)	No	No
E.T.	Massachusetts	No	—	No
J.W.	Illinois	Arizona (18 mos.)	No	No
E.W.	Missouri	Texas (Several short visits)	No	No

It will be observed from Table 2 that of the 17 cases who reacted to coccidioidin, 9 had lived in or visited one or more of the southwestern states. Only 8, or 1.2 per cent, of the remaining 659 boys who gave no history of residence in the southwestern states reacted to coccidioidin.

Of the 17 boys who reacted to coccidioidin, 12 failed to react to the intracutaneous injection of 0.01 and of 1.0 mg. of old tuberculin. Of this latter group 5 gave no definite medical history suggestive of coccidioidomycosis, although they showed definite calcified pulmonary nodules ranging in size from 2 to 8 mm. in diameter, located well out in the lung fields and in the hilar area; 4 of this group had at no time visited or lived in the Southwest. Of the 17 boys who reacted to coccidioidin, 2 gave a history of an illness suggestive of coccidioidomycosis and 8 had at no time been west of the Mississippi River.

The protean manifestations of infection with *Coccidioides immitis* and the variability in its severity have made it difficult to determine accurately whether

or not any of those who have reacted to the coccidioidin test have had clinical evidence of coccidioidomycosis. It is true that all of these individuals have at one time or another had an illness resembling influenza or grippe which in some instances may well have been due to *Coccidioides immitis*; obviously one can only speculate as to the diagnosis in these cases.

SUMMARY

1. Of 680 students at an eastern preparatory school for boys, 17, or 2.5 per cent, reacted to the intracutaneous injection of a 1:100 dilution of coccidioidin prepared on synthetic medium.

2. None of the 17 reactors had been previously diagnosed as having had coccidioidomycosis; however 9 of them had spent some time in one or more of the southwestern states, while 8 had never been west of the Mississippi River.

3. Of the 17 who reacted to coccidioidin, 12 failed to react to the intracutaneous injection of old tuberculin and 5 of these 12 showed calcified nodules on roentgenological examination.

Home and Farm Safety

A STATE-WIDE educational campaign for Home and Farm Safety was inaugurated in Albany, N. Y., on March 26 by the Division of Public Health Education of the New York State Department of Health. Represented at the Planning Conference were some sixty organizations, including four other state departments.

Unanimously the group voted to develop a state program under the original leadership of the State Department of Health and to arrange a state conference on May 28, in Syracuse. Burt R. Rickards, director of the Division of Public Health Education, was chosen permanent chairman and authorized to set up an advisory committee.

Stanley H. Kershaw, director of the Home and Farm Division of the National Safety Council, Inc., Chicago,

under whom the New York State program will be administered as part of a nation-wide campaign to reduce the 37,500 annual deaths from home and farm accidents, set a five point goal for the state as follows:

1. To determine quickly what has already been done about home and farm safety in the state.
2. To perfect state-wide organization with all possible speed.
3. To plan state, county, and community conferences.
4. To disseminate to all participating groups practical information on methods of combating problems.
5. To develop a plan for intensive follow-up work.

In addition to a stimulating program of discussions during the one day state conference in Syracuse, it was planned to have a group of exhibits, among which is featured a "House of Safety."

Isolation of Meningococcus from the Genitourinary Tract of Seven Patients*

CHARLES M. CARPENTER, M.D.,† AND RUTH CHARLES

*Department of Bacteriology, School of Hygiene and Public Health,
Johns Hopkins University, Baltimore, Md.*

THE isolation of the meningococcus from the genitourinary tract of patients with clinical evidence of gonococcal infection has not been reported in the literature. Epididymitis and seminal vesiculitis as complications of meningitis, however, are not infrequent.^{1,2} Pick,³ in 1907, isolated a meningococcus at autopsy from the abscessed seminal vesicles of a patient with cerebrospinal meningitis. The organism was differentiated from the gonococcus by carbohydrate fermentation and by serologic methods. Other authors have described the localization of the meningococcus in the genitourinary tract,^{4,5,6} but the identity of the organism was not established by carbohydrate fermentation. Recently, Branham⁷ identified as a Group II meningococcus a Gram-negative coccus that had been recovered from a case of urethritis diagnosed as gonococcal infection.

The present report describes the isolation of Group I meningococci from the genitourinary tract of 7 patients with symptoms of gonococcal infection.

PROCEDURE

In the course of investigations on the survival time of the gonococcus in

urine⁸ and on carriers in gonococcal infection, 103 strains of Gram-negative diplococci were isolated by standard cultural procedures.⁹ Because of the volume of work entailed, further identification by carbohydrate fermentation could not be carried out immediately. In most instances, therefore, the fourth or fifth generation of each strain or organism was preserved in a frozen state at -70°C . for approximately 1 month. The procedure followed was essentially that of Horsfall.¹⁰ The growth from a 24 hour chocolate agar slant was suspended in from 2 to 3 ml. of sterile defibrinated rabbit blood which was then pipetted to a sterile cork-stoppered celluloid tube especially designed to withstand low temperatures. The tube was immersed in a mixture of dry ice and 95 per cent alcohol at a temperature of -80°C ., after which it was stored in the freezing cabinet. In some instances, in addition to storage in the frozen state, duplicate cultures were maintained on chocolate agar.

Tests for carbohydrate fermentation were carried out on two different media. One was a tryptic digest agar to which were added 15 per cent ascitic fluid, Andrade's indicator, and a 1 per cent concentration of the desired carbohydrate, i.e., glucose, maltose, sucrose, or lactose. The other medium was Proteose

* Studies carried out in coöperation with the Division of Venereal Diseases of the United States Public Health Service and with the Baltimore City Health Department.

Read before the Laboratory Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

† On leave of absence from the School of Medicine and Dentistry of the University of Rochester as a Fellow of the Division of Medical Sciences of The Rockefeller Foundation.

No. 3 Agar,* in which an autoclaved supernate prepared from an aqueous suspension of dried Bacto* hemoglobin was employed as the enriching substance, and the respective carbohydrates added to yield a final concentration of 0.8 per cent. The indicator was phenol red. The fermentation reactions were carried out on several lots of each type of medium prepared at different intervals.

Seven strains, herein described, which failed to give the fermentation reactions of a gonococcus, were submitted to Dr.

growth on artificial media was more abundant than is typical of the gonococcus. Independent identification by Dr. Branham verified these findings, and further classified the strains as Group I meningococci.

The fermentation reactions of 5 strains were determined after preservation in the frozen state for 1 month. One strain (De) was tested shortly after isolation, and was not preserved by freezing.† The 7th strain (El) was maintained in duplicate, on chocolate agar as well as in the freezing cabinet.

Sara E. Branham, of the National Institute of Health, for independent identification. In her laboratory they were identified by means of carbohydrate fermentations, by the type of growth on blood agar, by "halo" production on agar containing antimeningococcal serum,^{11, 12} and by agglutination reactions with meningococcal typing serum.

RESULTS

Of 103 strains of Gram-negative diplococci that had been isolated from cases of gonorrhea, or from carriers of the infection, 7 proved to have the characteristics of the meningococcus, as evidenced by the fermentation of maltose as well as glucose. In addition,

The unfrozen agar culture fermented glucose only, while that preserved in the frozen state fermented both glucose and maltose, and was, therefore, identified as a meningococcus. A second culture recovered from patient El 70 days later was identified as the gonococcus.

A review of the clinical information on the 7 patients reveals no one factor which might explain the bacteriologic findings (Table 1). None of the patients was known to have had meningococcal infection, although this information was not ascertained for three of the group. Four had a history of previ-

† A culture from this patient, taken 1 month prior to the one reported herein, was identified as a gonococcus in the laboratory of Dr. Justina Hill, of the Brady Urological Institute.

* Difco Laboratories, Inc., Detroit, Mich.

ous attacks of gonococcal infection. Four had received sulfonamide therapy for the current infection before the culture was isolated; the remaining 3 had not had any chemotherapy.

DISCUSSION

The differentiation of the meningococcus from the gonococcus is a more difficult problem than is generally recognized. Recent investigations have shown that the two species possess similar basic biochemical constituents and a close immunological interrelationship. The methods for differentiating the one from the other are carbohydrate fermentation and serologic tests, especially those based on "halo" formation. At present the meningococcus is known to differ from the gonococcus principally in that it is capable of fermenting the disaccharide maltose and that strains in Group I elaborate a specific carbohydrate.¹³ As yet, a similar carbohydrate has not been demonstrated with certainty in the gonococcus.

The significance of the meningococcus in the genitourinary tract of patients with clinical symptoms of gonococcal infection is unknown. Only recently, Branham¹¹ pointed out that the gonococcus not infrequently invades the meninges and can be recovered from the spinal fluid. Although it has been known that these two species of *Neisseria* have many similar characteristics, both bacteriologic and serologic, our findings suggest still closer biologic relationship between the two organisms.

The source of the strains of meningococci recovered from the genitourinary tract raises some interesting questions. There are two possibilities, at least, to be considered. The meningococcus may have been introduced by contact with cases or carriers of the infection, or, the gonococcus may have acquired the biochemical activities of the meningococcus as a result of unusual environmental factors *in vivo*.

No single factor in the history of the 7 strains offers a possible explanation of the bacteriologic findings. At first, it might appear that freezing and storage at low temperatures had changed the biologic characteristics of a gonococcus, but the fact that one strain showed the characteristics of a meningococcus before as well as after freezing suggests that this is not a tenable explanation. Ostensibly, exposure *in vivo* to sulfonamide compounds cannot account for such a possible transition because 3 strains were recovered from untreated patients. On the other hand, until sufficient evidence has been accumulated to prove that sulfonamide compounds do not affect the characteristics of the gonococcus, this theory cannot be dismissed. The possibility of exposure of the organism to sulfonamide compounds in previous hosts must not be ignored.

The epidemiological significance of meningococci in the genitourinary tract may prove interesting. Similar findings have not been reported from laboratories in other sections of the country where large numbers of cultures from the genitourinary tract are examined for the gonococcus. The 7 strains described herein were isolated from residents of Baltimore. Of several hundred cultures of Gram-negative diplococci isolated from the genitourinary tract and identified by fermentation reactions in our own laboratories during the past decade, not one has proved to be the meningococcus, although both *Neisseria catarrhalis* and *Neisseria sicca* have not infrequently been recovered. It may be pointed out that the strains were recovered in the late winter and early spring, the season at which meningococcal meningitis is most prevalent.

Undoubtedly, as the cultural methods for the diagnosis of gonococcal infection become more universally employed in public health laboratories, additional data will be accumulated to interpret the significance of these observations.

SUMMARY

Seven strains of *Neisseria* having the biologic characteristics of Group I meningococci have been isolated from the genitourinary tract of 7 patients with clinical symptoms of gonococcal infection.

ACKNOWLEDGMENT—We are grateful to the staff of the Brady Urological Institute for their coöperation in this work and especially to Dr. Justina Hill.

Health Care in Defense

“THE first requisite of an effective working force; as of any army, is that it be well nourished, sufficiently well housed and clothed, and well cared for medically. The provision of essential health services to the whole population

cannot, therefore, be regarded as a luxury, as a ‘social gain’ to be shelved for the duration; rather, it is vital to the whole productive effort, as essential as oil to an engine.”

PRIORITIES IN PUBLIC HEALTH

THE military services will undoubtedly draw severely on the supply of able-bodied workers now employed by health departments and it will be difficult to replace these losses with equally competent persons. Budgets, too, may be reduced. Nevertheless, the need for providing basic public health services will be greater than before the war. In these circumstances, health agencies may be faced with the task of deciding which of their activities are the more essential and which, with reasonable safety, may be curtailed or for the time being eliminated. A choice here will be difficult. The raiment of public health programs has never included patch pockets and cuffed trousers and so it will not be a question of discarding the superfluous, but rather of deciding between the more important and the less important.

Unfortunately there is no formula in public health administration by which a decision may be reached as to the relative importance of all the elements which go to make up a public health program. One may roughly gauge the seriousness of a problem by the recorded mortality and morbidity, but the worth of such an index is limited by a number of factors: how nearly morbidity and mortality figures represent the true situation, as in syphilis; the potentialities for disaster inherent in a disease at present only sporadic in occurrence, as in smallpox; the age at which illness ordinarily occurs in any given disease; the length of illness; the fatality rate. Then, too, aside from the relative importance of a public health problem, one must consider the effectiveness and applicability of known control measures in relation to that problem. Knowledge as to prevention and control may be very meager, as in poliomyelitis, or even with known preventive and control measures, application may be difficult because it necessitates more restraint or more curbing of liberty than many people are willing to observe, as in measures for the control of venereal diseases.

Assuming, however, that some authoritative body could provide a formula which in the abstract would give a key to the relative importance of public health activities, conclusions so reached would not necessarily be applicable in all situations. And even if allowance is made for the varying necessities which must exist

in so vast and complex an area as the United States, it must be remembered that whatever is done in public health in any given state or locality must finally be decided on the basis of the convictions and personal opinions of the administrative officer responsible. These opinions, to say the least, would vary. But in spite of the difficulties inherent in any attempt to determine the relative importance of the different activities which go to make up a public health program and of thus establishing program priorities, there is a brighter side to the picture. There would be little difficulty, for instance, in getting agreement as to the necessity of maintaining maximum effectiveness in excreta disposal, in the provision of safe water supply, and in insuring safe milk. Further, certain responsibilities are imposed upon all health departments in connection with the control of acute communicable diseases, and these activities must, therefore, be given priority claims. It is probably fair to state, too, that many places now conducting ambitious public health programs would find the community benefited if less important activities were eliminated and, with the funds and time thus saved, there were provided better case finding and clinic facilities in chronic communicable diseases, especially the venereal diseases.

One could easily list other public health activities which most administrators would regard as essential. We hold no brief though for giving prior claims to any particular schedule of services. On the other hand, it does seem wise that those responsible consider how best they can contribute to the public health through the lean years ahead when staffs and budgets may be reduced to skeleton-like frameworks. Much undoubtedly could be accomplished by having one health officer serve where previously there were two; with better community organization and more participation by carefully directed lay groups; by a willingness to face the fact that in some areas programs are carried on intensively and extensively in this service or that because of tradition, personalities, and entrenched bureau strength, rather than because of the seriousness of the problem or the productiveness of the program. In any event, those interested in this subject, and most administrators will be interested, may find some aid in recent developments of the work of the Committee on Administrative Practice. A subcommittee of this group, responsible for the fact-finding schedules of the Health Conservation Contests, has indicated an admirable tendency to go through from the superstructure of health activities down toward their foundation. If no foundation is discovered, this Grading Committee takes the very logical attitude that the structure as a whole is unsound. Thus, if the public water supply is neither approved for safety nor available to most of the population, the entire sanitation program must be regarded as inadequate no matter how much laborious routine is attempted. Doubtless some might disagree with the conclusions in detail, but the method which this Grading Committee has adopted has much to commend it, and we suggest that those who are facing problems of priority in public health obtain the committee's aid in an effort to reach a wise decision on this matter.

PLANS FOR INSTRUCTION IN TROPICAL MEDICINE

IF against an atlas of the world one matches place names in the news of military and naval operations of the United States of America, a very high proportion of these names will be found to lie between the Tropics of Cancer and Capricorn, or not far north of the former or south of the latter. This means inevitably that

our expeditionary forces will be exposed to diseases endemic and epidemic in the hot countries and that officers of the medical and sanitary corps will be faced with the problems of prevention and control of such diseases. Because this is so, there has been a marked up-swing of interest in the general subject of tropical medicine, and many medical schools and schools of public health are quite wisely emphasizing instruction in these subjects.

The problem of maintaining health and controlling disease in the tropics is found not only in the physical environment, but also in the broader field of ecology. High temperatures and humidity, and intense solar radiation seriously handicap the newcomer; and these same conditions contribute generally to abundant propagation and survival of certain bacteria, protozoa, viruses, mycotic forms and insects which find man a desirable or necessary host. Against some of the diseases which exist, reasonably effective preventive measures have been developed. But the application of procedures for control will necessarily be limited where there must be rapid troop movements, the inauguration of temporary depots and lines of supply, and the emergency construction of roads. Troops entering these areas will go in without the naturally acquired immunity which most of the surviving natives will possess against many of the diseases. For these reasons, as well as for others, medical officers must not only be oriented as to formal and conventional methods in tropical medicine, but must in addition be so thoroughly familiar with their subject that they will be able to meet promptly the necessities of varying situations, to extemporize, and otherwise provide to the troops the maximum protection available in difficult circumstances.

It needs further to be emphasized that the prevention and control of tropical diseases is not a one man job. There is first, of course, the problem of diagnosis and treatment of those already affected by diseases with which physicians in this country are not now familiar. Second, there is the question of prophylaxis of the individual through vaccines, drugs, strict care as to food and drink, personal hygiene. Then come the larger measures of disposal of excreta, not only for troops but for adjacent populations, the location of camps, the choice and disinfection of water supplies, and measures which relate to the control of insects or protection from them. This, of course, is a generic rather than a detailed list of the problems which must be met, but it is sufficient to indicate that not only will the knowledge and skill of physicians be necessary but also the services of sanitary engineers, entomologists, parasitologists, bacteriologists, and others, including common laborers. Likewise, the teaching of these subjects will demand more than clinicians and microscopists.

In view of the situation to be met, all must commend and further the plan of instructing medical and public health personnel in the problems and control of diseases in the tropics. There is, however, one aspect it would seem wise to consider seriously. It is this: there seems some danger that, as occasionally happens in the teaching of other subjects, emphasis may be given to the exotic and dramatic diseases of the tropics rather than to those which, though constituting far greater hazards, have lost their appeal because of previous though desultory interest in them. For instance, one is likely to be intrigued with the picture of an elephantoid scrotum so large that the individual must trundle it before him in a wheelbarrow. This sort of thing, of course, is to the surgeon as is a red flag to a bull. He wants to do something about it and can. Actually, though, while some of our troops will undoubtedly get filarial infections, the results will be not nearly

so disastrous as they are likely to be from the lowly and familiar dysenteries. Again, the very names of some of the tropical diseases carry within themselves threat and mystery: Schistosomiasis, Trypanosomiasis, Calabar swelling, Dumdum fever, Verruga Peruviana, Pappataci fever, etc. But all these added together will probably be of no moment when compared with what must be faced in connection with malaria. Yellow fever may, of course, be of serious concern, and is a subject upon which officers of the medical and sanitary corps should be well informed. Fortunately our troops will go into tropical areas vaccinated against this disease. Also, troops in certain parts of the Orient may face a menace in local cholera situations, and it is possible that typhus and plague, though not confined to the tropics, may be endemic in areas of military operations. Dengue, too, may render high proportions of troops simultaneously and temporarily non-effective. But most of these diseases are limited geographically, are absent in many parts of the tropics, or are not necessarily highly endemic. Malaria and the dysenteries, on the other hand, are practically everywhere in the warm countries, and although in considering them one may not through an association of ideas experience the thrill and glamour of blue seas and waving palms, the medical officer, in studying tropical epidemiology and ecology, would do well to major in these two diseases which are almost unlimited in their capacity to produce illness and death.

What and Who Is an Epidemiologist?

Comments on an editorial published in the April, 1942, issue of the Journal:

C. F. Adams, M.D., Director of Laboratories of the State Board of Health of Missouri, Jefferson City, writes: "I should say that an epidemiologist is a physician (M.D.) who investigates the presence (diagnosis), extent, source (water, food, air, etc.), and control of an epidemic or outbreak of any disease. He would use, either in person or through others, many subsidiary sciences, such as bacteriology, protozoology, helminthology, medical entomology, mycology, chemistry, sanitary engineering, and at times statistical methods. These subsidiary sciences generally would be represented by others in a consultative relationship.

"In other words, an epidemiologist is a medical inspector who goes into a community to find the *what* and *why* and *control* of an outbreak of any disease.

"The epidemiologist would, no doubt, become interested in past epidemics, and would marshal a vast material relative to duration and source, and in this regard his statistical methods would be one of his most powerful instruments.

"As a paleontologist is a zoölogist studying prehistoric fauna, so the epidemiologist would be, in this case, a physician investigating past outbreaks of disease."

WHAT THE PUBLIC WANTS TO HEAR

"Foot health is vital to victory—Wear our scientifically fitted shoes"

"Get your health from the sea—Eat fish for victory"

These slogans (if they may be called such) typify the extremes to which some advertisers go to stress the relationship of their products to the two subjects that now seem to be uppermost in the public's consciousness—victory and health. Perhaps you have seen similar examples and have also been struck by their absurdity. Although it may be difficult to control this cheap sort of health exploitation, we feel it our duty to "go on record" as having raised our voices in protest. Now, of all times, it is not only inappropriate but downright unpatriotic to couple health with questionable ballyhoo.

Perhaps, after all, the public is not much impressed by such advertising copy. Certainly few are gullible enough to believe that the war effort and the nation's health are vitally dependent upon "scientifically fitted" shoes and daily portions of broiled mackerel. Yet claims of this sort may actually prevent the full realization of the potential war effort as they contribute nothing to the psychological drive so necessary to a country at war.

And this brings us around to the question of what the public *does* want to be told today—a question that should concern health educators. W. J. Weir,

Please address samples of printed matter, comments, or other editorial contributions to the editors at One Madison Avenue, New York, N. Y.

in a recent issue of *Printers' Ink*, made a forceful statement along these lines. Most of us will agree with Mr. Weir that the public wants to be told many of the following things:

We want to be told—not to remember Pearl Harbor. We want to be told to take Tokyo, to bomb Berlin, to raze Rome.

We want to be told—not to help keep our world and our way of life from being lost. We want to be told to help build a *new* world and a *better* way of life.

We want to be told—not to buy Defense Stamps or Defense Bonds. We want to be told to buy *Victory* Stamps or *War* Bonds.

We want to be told—not to do our part to keep Naziism or Fascism from these shores. We want to be told to do our part to spread Americanism to *all* shores.

We want to be told to sing battle songs. Don't tell us there'll be bluebirds over the white cliffs of Dover. To hell with bluebirds. Tell us there'll be vultures and a deathly silence over Berchtesgaden.

We want to be told that we are going to win lebensraum for our democratic way of life.

According to *Printers' Ink*, these are the things the public wants to hear! Many would like to see more publicity emphasizing most of these angles—and less ballyhooing of dubious approaches to health and victory.

AN EDITORIALETTE:

HEALTH EDUCATION IN PUBLIC HEALTH

While the factor of health education in public health is not *all* important, it is indeed vital to all other elements in public health and preventive medicine as practised in the modern community. Health education helps to create its associate units essential in a basic health program. It should permeate all of

these related services and influences. On the other hand, without these concrete services, such as medical examinations in schools, clinic facilities in health centers, examination services in industry, health education tends to remain a highly intangible, theoretical, abstract and largely futile commodity. It finds its substantiation in its relationship to these practical services. It is visualized, precipitated, brought out of the realm of theory by its contact with its basic service colleagues. It, therefore, has a creatively reciprocal relationship with the other elements in public health. It enhances their value and reality, and finds its own realization through them. *Health education is the one element in our health program that contributes most to making the whole public health effort substantially greater than the sum of its parts!*

RECENT HEALTH PUBLICATIONS

At this time of the year, reports—annual and otherwise—blossom forth in clusters. One of the best of the current crop comes from the W. K. Kellogg Foundation of Battle Creek, Mich. Under the title, "The First Eleven Years," the varied activities undertaken by this great agency since its inception are discussed and pictured in a highly effective manner. The work of the Kellogg Foundation is well known to workers in public health, its innovations in many fields having placed it in the forefront among agencies of its kind. But one will gain a new and fuller appreciation of the Foundation upon reading this excellently prepared summary. It is reassuring in times like these to find so much emphasis on the part of the Foundation upon democratic principles and their relation to successful community enterprises. It is also reassuring to note that the Foundation does not plan to rest on its laurels but is already looking to the future, planning greater achievements. The Founda-

tion staff is to be congratulated on its report which is handsomely bound, well written, well organized, and illustrated with a wealth of good photographs.

The 1941 report of the Georgia Warm Springs Foundation sets forth the highlights of another fruitful year of work in the medical care and treatment of infantile paralysis victims. This compact report includes a foreword by Franklin D. Roosevelt, a series of striking photographs which "catch" the cheerful atmosphere of the institution, and pertinent information regarding the history, current activities, and financial affairs of the Foundation. From the standpoint of make-up, the 1941 report is noted for its clean simplicity of type and layout. Copies may be secured from the Foundation, Warm Springs, Ga.

"Something new has been added" to the health library of the John Hancock Mutual Life Insurance Company, the title of which is "Guarding Your Family's Health." This recent publication, authored by Wilson G. Smillie, M.D., is devoted to general health information. Readers will find here an interesting and illuminating discussion of modern public health facilities, and what they mean in terms of the individual's welfare. The publication gives due recognition to the work of nonofficial agencies and group medical prepayment associations. The format of the booklet is most attractive and the cover design and illustrations are done with distinction. *Guarding Your Family's Health* is available without cost from the Life Conservation Service of the John Hancock Life Insurance Company, Boston, Mass.

Farm and home safety is becoming a subject of increasing interest to health departments, as evidenced by recent meetings at which programs to combat this part of the safety problem were formulated. Thus health workers will

find a new publication of the International Harvester Company particularly timely and valuable. Under the title of "Stop Carelessness! Prevent Accidents!" a most comprehensive survey of every type of accident hazard on the farm and in the home is presented. This publication contains a valuable collection of photographs illustrating conditions that often lead to injury or death. There is excellent teaching material in this booklet. Several pages of first aid information are also included in the contents. Copies are available without cost from the International Harvester Company, 180 North Michigan Avenue, Chicago, Ill.

Two significant articles from recent issues of *Hygeia* have been issued in reprint form by the American Medical Association. "Our Selectees Are Healthier" is the title of one. It deserves wide distribution, as a great deal of misleading information has been circulated about the state of the national health. This authentic analysis of the draft rejections and health conditions in the armed forces will go a long way toward reassuring the public that the nation's general health was never better. The second *Hygeia* article, available in reprint form, is entitled "Health at the Crossroads." This article stresses the resources of the modern health department and their rôle in the community of today. Both reprints deserve wide use. Write to the A.M.A., 535 North Dearborn Street, Chicago, for quantity prices or send 10 cents for a single copy.

To health workers particularly interested in the development of school health programs, a bulletin outlining the school health policy of Ohio can be highly recommended. This publication outlines in a concise but complete manner the objectives and the fundamental principles underlying Ohio's school health education program. In reviewing

this bulletin, one is impressed with the well rounded nature of the program and the emphasis placed upon coöperative relationships. "No local school health program is able to function properly as an isolated endeavor, for it must be a coöperative effort of school, home, community, and state in the interest of the whole child and the future citizen," the bulletin states. The Advisory Committee on Health Education of the Ohio Public Health Association is to be commended for its work in defining and coördinating the state's school health education program. Copies of the bulletin may be secured from the Association, 1575 Neil Avenue, Columbus, Ohio. Single copies are priced at 20 cents.

A simple vest-pocket leaflet on syphilis and gonorrhea has been issued by the State Department of Health of New Jersey. This publication is unique in that it minces no words about prostitution, alcohol, and prophylactic procedures. Heretofore, venereal disease literature marked by such frankness has been distributed chiefly to men in our armed forces. The New Jersey health authorities, however, maintain that the war effort "now makes it very important that the civilian population be given instruction as to the prevention of these diseases." The New Jersey leaflet amply "fills the bill." Copies may be had by writing the State Department of Health at Trenton.

The Division of Maternal and Child Health of the Montana State Board of Health has prepared a series of nine prenatal letters which are sent directly to patients under the care of physicians. The content of these letters covers practically every topic about which the prospective mother is concerned. The text of each is direct and informative. We suspect that these letters not only serve an educational purpose, but also save "wear and tear" on the physician

who might otherwise be required more frequently to travel long distances in the wide open spaces to visit patients more in need of simple information than actual medical care. Copies of the letters are available from the Montana State Board of Health at Helena. They are well worth the attention of all workers in maternal health programs.

—
Group voluntary (prepayment for medical costs) health associations are springing up in many sections of the country today and it appears that a new type of health education material may be expected from these associations. In fact, one of the leading agencies of this type in New York State—the Group Health Cooperative—has recently inaugurated a popular health bulletin for its subscribers. The content of the first two numbers emphasizes several timely health topics—including individual health in national defense, nutrition, keeping fit in the city, etc. There are also news items concerning affairs of the Cooperative and developments in the public health field of general interest. The bulletins are sound in content and well conceived editorially. Congratulations to Winslow Carlton, Executive Director of the Group Health Cooperative, 1790 Broadway, New York, N. Y.

INFORMATION ON MOVIES

Motion pictures are perhaps our most popular medium of health education. It is doubtful, however, if we have learned to use films as skillfully as we might. Studies throwing light on this important tool of instruction are consequently of considerable value.

A survey recently concluded by the Health Education Service of the National Tuberculosis Association, while it dealt only with films on the tuberculosis problem, nevertheless brings out many pertinent facts that all producers of health films would do well to study.

According to replies received in answer to a questionnaire, the "composite" tuberculosis secretary prefers (1) a motion picture in *drama* form, (2) appealing to the *general public*, (3) for the purpose of *teaching people* what to do for themselves, (4) emphasizing the *x-ray*, and (5) with a running time of *15 minutes*.

The N.T.A.'s survey also elicited criticism as to what's wrong with health movies. Poor craftsmanship topped the list of critical barbs. In reply to this, the N.T.A. states: "We make no excuse for poor craftsmanship, but remember we do not aspire to match the finest Hollywood products. We want sincerity, simplicity, and realness, even at the sacrifice of photogenic quality. Our films must be entertaining, but essentially they are designed to teach, persuade, to win support of tuberculosis control work." Criticisms were also voiced regarding the quality of sound recording. In reply to this it was pointed out that complaints on this score are often unjustified, as the operator, the projector, or the acoustic properties of the room are most frequently responsible for unsatisfactory sound.

For what purpose are tuberculosis films needed? The following varied answers were given to this question: (1) to teach people what to do for themselves, (2) to inform people about modern facilities, (3) to stimulate leaders to support tuberculosis control measures, (4) to relate tuberculosis to some social problem, such as housing and nutrition, (5) to build good will.

The survey disclosed that films should be developed that appeal to the general public. "Movies should have a universal appeal for people in all walks of life rather than for those of a special or chosen group."

As to types of treatment, the dramatic form of movie is preferred even though it is difficult to convey an educational message by means of dialogue.

Instructional, cartoon, documentary, and didactic narration films were among the other types of films suggested by those who answered the questionnaire.

In regard to length, the 15 minute film was deemed most serviceable, while some of the individuals polled preferred movies running to 20 minutes.

Surveys of this nature will go a long way toward helping health educators understand better the rôle of films in the educational field, their possibilities, and limitations.

Since the users of tuberculosis films voted for more pictures emphasizing the x-ray, it might be well for those charged with the production of future movies, and other educational materials, to guard against overemphasis. Due recognition should be given to the other participating factors in the tuberculosis control program, including the private medical practitioner.

AT LAST—EDUCATION PAYS

Welcome news comes from the American Medical Association concerning *Hygeia, The Health Magazine*. In the Association's annual report to its officers, the statement is made that "for the first time in several years *Hygeia* credits were greater than debits, in the sum of \$15,738.06." It may be safely said that such a favorable balance has probably not often prevailed in the history of a publication devoted to education and service rather than to profit making. Moreover, the A.M.A. has abundantly demonstrated the utility and practical feasibility of a major publication dealing popularly with health education and disease prevention. Many years ago when *Hygeia* was launched there were, among those in the medical and public health professions, probably more skeptics than optimists regarding its financial future. It must be especially gratifying to the staff of *Hygeia* to find the publication prospering at a time when so many established journals

are merely "getting by," because of diminishing advertising revenue.

While *Hygeia* now has 114,000 regular subscribers, it merits a larger audience. The magazine has constantly improved in editorial content, as evidenced by the number of articles which *The Reader's Digest* draws from its pages. Moreover, *Hygeia* is widely quoted in the press and over the radio. The magazine's art staff also deserves credit for the general excellence of the publication's illustrations and format.

We wish continued years of prosperity to this valuable magazine and hope that its health messages will reach an ever widening circle of readers.

PUBLICITY TIPS FOR THE DURATION

Representatives of several health organizations in New York City recently participated in a round-table discussion on "Health Education in Wartime." Some of the observations growing out of this meeting are of interest to health workers generally.

The participants considered ways and means of putting the health educator's message before the public despite the limitation of newspaper space growing out of the increased volume of war news. To insure acceptance of health news, it was recommended that only newsworthy material be presented to editors, that stories be submitted in the form of press releases so that rewriting is not required, and that all material be checked thoroughly to make sure that it contains no information of aid to the enemy.

The relationship of health to the war effort was another topic receiving attention. It was the feeling of the participants that material stressing the tie-up between health and the war must be presented gradually to newspapers and not overdone. Editors are receptive to news on tuberculosis, nutrition, syphilis, the prevention of blindness, nursing, and the like, because these subjects

have a clear-cut bearing upon the war effort. Because of the war, women's page editors are more interested in health news than ever before. In this connection, it is well to remember that health news may be used again and again if each time it is presented from a fresh and new angle. After health education information is presented to the public through newspapers, it should be followed up through the use of other media—such as the radio, the health lecture, or through nurses during home visits.

Concerning the use of radio, it was pointed out that pressure upon broadcasting stations for time is increasing because of the many war activities that must be aired. Thus the standards of health education broadcasts must be raised if they are to be presented via radio. One of the networks that has accepted health material for presentation has suggested that a way of improving the content of health broadcasts lies in the development of a definite radio character or personality to deliver weekly talks. In this way a stress of continuity may be established and a definite audience gained. This scheme has been successfully carried out by the New York State Department of Health through its radio character "Dr. Jones" and by the Baltimore City Health Department through its "Dr. Ashley."

Another plan to improve broadcasting is being developed by the New York Academy of Medicine, in coöperation with the major chains. Here an attempt is being made to bring together the professional man, who knows his subject but is not an expert in radio presentation, and the radio authority with extensive experience in the effective use of the air for entertainment or advertising purposes. Prior to the radio address, these two experts from different fields will try to shape the form and content of the health message so as to increase its utility through this medium. This

experiment will be studied with very great interest.

CONCERNING A POSTER

Booklets, posters, and other publicity materials issued for use in safety education are becoming increasingly effective. Excellent examples of publicity material are available today from a number of safety organizations, particularly the National Safety Council, 20 North Wacker Drive, Chicago, Ill. Outstanding among the Council's current publicity media is a series of war posters, the sixth of which is now ready for use. It is such a splendid example of poster art that it deserves special mention in these columns. Three statements—Keep 'em Fighting, Production Wins Wars, Stop Accidents—are grouped around a handsome painting of a sailor loading ammunition. The expert way in which the text and the illustration have been handled results in a poster that has great impact. Wherever this poster is displayed it will certainly stop passers-by in their tracks. Posters like this are an excellent contribution to the nation's war effort.

Health educators—take note of the work that our colleagues in the safety field are doing. There is much that we can learn from them.

FOR YOUR RADIO PROGRAM

The government needs 50,000 well qualified students to enter schools of nursing. It is an urgent need and every health agency in the country should aid in the publicity drive that is now in progress to enroll young women in the profession. Excellent publicity materials are available, including two 15 minute radio programs which have been recorded by the Nursing Council on National Defense. The recordings are entitled "Night Nurse" and "Public Health Nurse," and to date they have been broadcast by almost 500 radio stations. Has your local station pre-

sented them? If not, these dramatizations should be offered to the program director.

The scripts of both dramatizations are full of items of human interest and at the same time they impress upon the listener the fact that the nursing profession offers an unequalled opportunity for service to humanity in times of peace as well as in times of war. The dramatizations are so well presented that any program director should welcome them for a prominent "spot" on his evening schedule. Each script ends with an appeal to young women—Mrs. Franklin D. Roosevelt speaking on the "Night Nurse" recording and Surgeon General Parran on the "Public Health Nurse" program.

Inquiries concerning the double-faced recording of these scripts should be addressed to David Resnick, Public Information Consultant, Nursing Council on National Defense, 262 Madison Avenue, New York, N. Y.

Other interesting and timely radio material that can be used to great advantage now may be obtained from the National Society for the Prevention of Blindness, 1790 Broadway, New York, N. Y. The Society offers two transcriptions, free of charge, to any health organizations that may wish to use them. "Eyes for America's Future" is the title of one of the transcriptions. It stresses the fact that good eyes are not only essential for men in military service, but they are also necessary for skilled craftsmanship in the shop. The second transcription is called "Man Was Born to See." It deals with some of the more common causes of blindness and how loss of sight may be prevented.

MAGAZINE ARTICLES

Current popular magazine articles on health or of medical import:

"Keep Up with Medicine" (a new monthly feature). *Good Housekeeping*, May, 1942.

"Doctors in Uniform." Maxine Davis. *Cosmopolitan*, May, 1942.

"Why Teachers Are Neurotic." Frances V. Rummell. *Good Housekeeping*, May, 1942.

"The Army's Menu Maker." Maxine Davis. *Coronet Magazine*, May, 1942.

"A Working Cure for Athlete's Foot." Paul de Kruif. *The Reader's Digest*, May, 1942.

"Nerves in the War." George W. Gray. *Harper's Magazine*, May, 1942.

"Skyscraper of Healing." William McDermott. *Coronet Magazine*, May, 1942.

"What We Know about Vitamins." Waldemar Kaempffert. *New York Times Magazine*, May 3, 1942.

"Fun in a Dentist's Chair." William F. McDermott. *Coronet Magazine*, April, 1942.

"Death in a Drinking Fountain." Michael Evans. *Coronet Magazine*, April, 1942.

(The above is not presented as a complete list and the articles cited are not necessarily recommended.)

JOTTINGS

The appointment of Dr. Benjamin G. Horning as Chairman of the Ninth Institute on Health Education has occasioned much favorable comment. Dr. Horning's varied experience in public health gives reassurance that the forthcoming Institute program will be in capable hands. Dr. Ira V. Hiscock, who is largely responsible for the growth and success of previous Institutes, will be missed by one and all. . . . We understand that serious consideration is being given by the New York Academy of Medicine to having its library index and catalogue the more important and significant health education reports and publications—a service that should be of value in the future. . . . Suggested slogan for public health workers: "Help to save lives—Help to win the war." . . .

Another slogan from Elda Robb of Simmons College Home Economics Department: "People who are 'all in' cannot go 'all out' for defense." . . . Joke of the month: "I do hope you keep your cows in a pasture," said Mrs. Newlywed as she paid the milkman. "You see, the health department says pasteurized milk is much the best." . . . Are you familiar with the film program of the General Electric Company? Many of the pictures produced by this organization deal with scientific subjects—x-rays, the biology, of microscopic life, research, and the like. A catalogue listing all films available from this source may be obtained by writing the Visual Instruction Section, General Electric Company, Schenectady, N. Y. . . . Quotation from Ralph Waldo Emerson: "Education is not pouring knowledge into minds; it is not erudition. A person is not truly educated unless knowledge influences his *doing* as well as his *thinking*. In so far as learning alters and directs *behavior* it is education." . . . A city-wide immunization campaign against whooping cough was undertaken recently by the Boston Health Department. . . . An interesting and valuable series of lectures and discussions has been taking place monthly since January, 1942, with one lecture concluding the series in May, dealing with health education from the angles of nutrition, mental hygiene, sociology, advertising and public health. This series represents the first joint effort in

this direction by the New York City Welfare Council and the Academy of Medicine, the lectures being open to members of the staffs of the many agencies participating in the Welfare Council. The April meeting, presided over as usual by Dr. D. B. Armstrong, was enlivened by an excellent presentation by John Benson, President of the American Association of Advertising Agencies, on the contribution of commercial advertising to health education. . . . We hear interesting reports of an experiment that is now in progress to evaluate the teaching performance of public health nurses. A microphone, disguised as an inkwell, is placed on a desk in the room where nurses interview patients. The conversation between the nurse and the patient is picked up by the microphone and recorded. Later the record of the interview is studied to determine the effectiveness of the nurse as a teacher, the patient's reaction, and the like. . . . The technical Committee on Evaluation of Motion Pictures of the New York City Nutrition Program has reviewed 37 films on food and nutrition and rated them according to accuracy of subject matter, organization of material, quality of film presentation, and educational value. The committee's report will be published during the summer by the American Film Center. The preliminary report indicates that this will be a most valuable guide for organizations using films in nutrition programs.

BOOKS AND REPORTS

Communicable Disease Control—
*(A Volume for the Health Officer and
 Public Health Nurse)*—By Gaylord W.
 Anderson and Margaret G. Arnstein.
 New York: Macmillan, 1941. 434 pp.
 Price, \$4.25.

This book is divided into two parts, in the first of which the principles underlying communicable disease control are discussed. The difficult task of summarizing the historical background and generally accepted theories of epidemiology and disease control is for the most part handled satisfactorily and with avoidance of sweeping generalizations and discursive writing. In fact, the authors have apparently exercised so much care in selecting and qualifying words and phrases that at times their style is slightly laborious and certain passages are somewhat difficult to read. Chapters in the first part of the book deal with the organization of health services, the legal aspects of the subject, the rôle of the public health nurse, and nursing care in the home. Methods of investigation and analysis of data are covered in another chapter.

The second part of the book contains brief descriptions of individual diseases and the steps to be taken during their investigation and management. Each disease is treated more or less uniformly, with specific recommendations as to the functions and responsibilities of the health officer and the public health nurse in prevention and control. Presentations of material on clinical aspects, the epidemiology of individual diseases, and the administrative features of their control are nicely balanced as to space and content. But the book is much more than an ordinary reference manual or a dry compilation of facts regarding the diseases covered. It reflects the wide experience of the authors and contains

valuable hints and practical suggestions that are obviously the result of first hand observations and study in the field.

Statements and opinions expressed throughout the book are in general accurate and in conformity with the most recent discoveries and beliefs. Some authorities would take exception to using the term "infected" to describe contaminated water and milk supplies, since infection implies multiplication of the causative agent in the medium. The authors state that references at the end of each chapter have been selected on a basis of easy access and are not all-inclusive. In view of some of the references to recent contributions which have been included there are rather surprising omissions, such as the tuberculosis studies of Stewart and his associates, and the original paper on the transmission of yellow fever to monkeys by Stokes, Bauer, and Hudson.

As a useful summary of American practice, and because it brings together in a unique manner the functions of the health officer and the public health nurse, the book is to be recommended to all workers in communicable disease control.

GEORGE H. RAMSEY

**Modern Bread from the Viewpoint
 of Nutrition**—By Henry C. Sherman
 and Constance S. Pearson. New York:
 Macmillan, 1942. 118 pp. Price, \$1.75.

This short summary on bread will be most helpful to all health workers since many of the questions which they are continually asked are answered in this book. The authors point out that while staple white bread has been highly developed and standardized technologically, little attention has been given to its nutritive value. The breads of a century ago, those of a decade ago, and those now being introduced all have

energy values of about 1,200 calories per pound, but they differ greatly in protein value and in mineral and vitamin content. Special emphasis is given to the loss of mineral elements and B vitamins as a result of modern milling methods and the various procedures now being used for correcting these deficiencies. The requirements proposed by the Food and Drug Administration for enriched breads are given.

The authors are to be complimented on the last chapter in which emphasis is given to the fact that for some years to come the bread problem will present a tentative or transition aspect from more than one point of view.

C. A. ELVEHJEM

Industrial Surgery—By Willis W. Lasher, M.D. (rev. 1st ed.). New York: Hoeber, 1942. 472 pp. Price, \$6.50.

This is an enlarged first edition of the book originally published in 1938. It contains 472 pages, 194 illustrations, a bibliography of 237 references, and a 22 page appendix replete with illustrations of splints and appliances. Its 26 chapters cover the diagnosis, treatment, and industrial considerations of injuries of virtually every part of the body. Included also are the organization and equipment of industrial medical departments and two new chapters, one on strains and sprains, and the other on chemotherapy.

The foundation of this book is formed by the extensive experience of the author. He freely expresses his personal opinions and conclusions, the book abounding in brief, illustrative case reports. Though definitely a monograph, Dr. Lasher repeatedly refers to opinions and methods of others, reference always being made to the extensive bibliography appended. Medico-legal phases of injuries are discussed in ample detail, the exact scheduled awards of specific instances often being given. The com-

pensability of various ailments and injuries is given due prominence. Though no special section is devoted to them, the reader can readily locate, by use of the index, discussions on subjects such as osteomyelitis, burns, skin grafting, malingering, and amputations.

To include such a vast amount of material in one book is indeed noteworthy and, not realizing that all subjects are never covered with equal detail by any one author, some readers may wish for more discussion of certain subjects, for example: the treatment of compound fractures, the symptomatology of the protruded inter-vertebral disc, chronic sub-dural hematoma, the initial cleansing of burns, the use of plasma in shock, and the injection treatment of fibrositic areas.

The entire book is intensely practical. Not only is the whole field of industrial surgery covered, but detailed information is given (including illustrations) concerning treatment of all manner of injuries.

With industry geared toward a tremendous war effort, industrial surgery is a most vital subject. Therefore, not only to the industrial physician, but to the general practitioner as well, will this book hold great appeal.

FREDERICK W. SLOBE

Developmental Diagnosis—Normal and Abnormal Child Development—By Arnold Gesell and Catherine S. Amatruda. New York: Hoeber, 1941. 447 pp. Price, \$6.50.

The authors of this unique volume have brought together an enormous mass of material gathered from the Yale Clinic of Child Development and have organized it in such a practical manner as to be highly useful to clinicians and others concerned with normal and abnormal development of children. It carries forward the pioneer work of Arnold Gesell and his associates into a practical field.

The book is organized around three main sections, namely, Principles and Methods, Defects and Deviations of Development, and The Protection of Early Childhood Development, any one of which may be taken as a complete unit.

The authors consider Chapter III in Part I as "the most basic in the book, because it integrates the developmental tests, the behavior characteristics, and the growth trends of the behavior patterns for the period from four weeks to three years. This chapter is organized for convenient reference and is illustrated with over 100 photo-tracings of normative behavior patterns."

This volume cannot fail to have a profound influence upon methodology in the study of young children and upon the supervision of their health and development based upon exact and exhaustive observations.

Developmental Diagnosis is not a book of passing interest, but a volume of reference for some time to come.

RICHARD A. BOLT

The Microbe's Challenge — By Frederick Eberson, Ph.D., M.D. Lancaster, Pa.: Jacques Cattell Press, 1941. 352 pp. Price, \$3.50.

Dr. Frederick Eberson's book *The Microbe's Challenge* is one of the best and ablest versions of the story of bacteriology. It is completely unlike any of the previously published versions. Dr. Eberson is master of a happy style. At no time vulgar, his recitation reads smoothly and sustains interest from beginning to end. This work is a topnotch illustration of the thesis that competent popularization does not necessarily involve the sacrifice of factual truth or of good taste.

The book is a scholarly review of the history of the development of the signs of bacteriology. It is also a good "teaching work"; the reader of this book will not only learn to know but

also to understand the intricacies of bacteriology. The work brings the subject right down to the present day and includes such current matters as the viruses, bacteriophage, and experimental epidemiology.

The work has been composed, as the author states in his preface, from the point of view of *Microbes Versus Man*, and several times there is repeated in the text, Pasteur's grand hope "that it is within the power of man to cause all parasitic disease to disappear from the world." Time past, there was the hope that the science of bacteriology might offer the instrumentalities for this achievement. We now know that this hope was vain. The author so acknowledges it but, in this reviewer's opinion, not with sufficient emphasis. The belief that the primary cause of parasitic diseases is the parasite is open to serious challenge.

The weaker chapter in this otherwise excellent book is the 9th, entitled "Epidemics to Order." The author appears to have misread the studies of Greenwood, Webster, etc. These studies bear upon the dynamics of epidemics, that is, the propagation of epidemic diseases in herds of experimental animals living under artificial conditions. These studies do not illuminate the etiology of natural diseases of epidemic dimensions.

Apart from these minor criticisms *The Microbe's Challenge* is a work to be highly commended to health educators, public health workers, medical students, and to physicians. I know of no better summary of the subject matter.

IAGO GALDSTON

Vital Statistics of the United States, 1939—U. S. Department of Commerce, Bureau of the Census. U. S. Govt. Printing Office, Washington D. C., 1941. Part I—Place of Occurrence, 531 pp. \$1.50. Part II—Place of Residence, 283 pp. \$1.25.

Here we have the maximum of

economy and efficiency of presentation of our nation's births and deaths. The arrangement is logical and convenient, permits easy finding and use of the tabulated facts and rates based upon them. The introductory pages are adequately explanatory and, dealing as they do with the two major topics of natality and mortality by place of occurrence and place of residence separately, the text is more direct and comprehensive than in some earlier volumes. The natality and mortality data for the United States tabulated by place of occurrence and by place of residence, with supplemental tables for Hawaii, Puerto Rico, and the Virgin Islands, is a priceless addition to a shelf of equally precious predecessors.

These two volumes are more convenient to handle, save more lost motion and waste of eyesight than any of their predecessors, while presenting practically all the essential data other than such as may properly be classed as hand-picked and of a research nature. The supervision of Dr. Halbert L. Dunn, the Chief Statistician for Vital Statistics, is of itself a guarantee of the scholarship of the brief, succinct text and the authenticity of the tabular matter.

HAVEN EMERSON

A History of Medical Psychology
—By Gregory Zilboorg, M.D. In collaboration with George W. Henry, M.D. New York: Norton, 1941. 606 pp. Price, \$5.00.

This book presents the story of man's interest in his own behavior and that of his fellows over a period from before the 4th century B.C. to the present time. Its chapters are entitled Primitive and Oriental Medical Psychologies; The Greeks and Romans; The Great Decline; The Restless Surrender to Demonology; The Blows of the Witches' Hammer; The First Psychiatric Revolution; The Age of Reconstruction; The Discovery of Neuroses; The Era of

Systems; The Second Psychiatric Revolution; Epilogue; Organic Mental Diseases; and Mental Hospitals. These pages present a tremendous amount of honest effort to portray the long, tedious and gloomy journey of metaphysics, psychology, psychiatry, and medicine toward an understanding of mental health and a humanistic tolerance of all its relationships to society and its problems of living. Aside from the objective of presenting a faithful background of historical facts the text develops in its progress that "although officially a branch of medicine, psychiatry was accepted into the brotherhood of medical efforts only on sufferance, only on the condition that it accept in advance the tenets of medicine and consider that disease means physical disease, and that mental disease be included in the organic realm of things." It is a truth that should be thought provoking.

This book should be in the library of every medical school and hospital as a valuable source of reference and collateral reading.

ESTHER LORING RICHARDS

Professional Dentistry in American Society—By Alfred J. Asgis, Ph.D., D.D.S. New York: Clinical Press, 1941. 260 pp. Price, \$4.50.

The author of this interesting book has given more than the usual consideration to the relation of the profession of dentistry to society at large. He brings into the forefront some of the responsibilities of one to the other, and suggests that dentistry as a profession must give a constantly increasing amount of thought to fulfilling its obligations to society, while, on the other hand, society must not overlook its responsibility to the profession.

In addition to urging society and dentistry to realize the necessity for shared responsibility and concerted effort, Dr. Asgis relates events which lead to the recognition of dentistry as a pro-

fession. The pattern and trend of past and present dental education are traced and its future discussed in a stimulating and thought provoking manner.

This book serves a useful purpose, and should be of particular aid to the non-dental health worker who may have an interest in or responsibility for the integration of dental activities in a general public health program.

BION R. EAST

Determining Work Loads for Professional Staff in a Public Welfare Agency—By Herbert A. Simon, William R. Divine, W. Myles Cooper, and Milton Chernin. Berkley: Bureau of Public Administration, University of California, 1941. 94 pp. Price, \$1.00.

This is a nice bit of job analysis which so impressed the California State Relief Administration that part of the recommendations were put into practice. The major functions of the social workers in the local branches of the state organization are to determine eligibility for relief and to reinvestigate the eligibility of active cases. Their function was not to administer relief. The problem was to determine from the standpoint of efficiency and cost how large a case load should be given workers at different stages of the job. The more workers employed, the greater the operating expense. And yet with too few workers accuracy in approving eligibles was reduced, people stayed on relief longer than necessary, and the expenditure for relief clients was greater. Where is the desirable middle ground?

There are three distinct steps in the job. The first contact of the client is with the "qualifier" who after a prolonged personal interview approves or disapproves the application. Those approved go to the "field intake" group who check up the application by a home visit and approve or disapprove. And finally the "carrier" group periodically visits cases receiving relief to make

sure that the eligibility requirements have not changed.

The experiment was carried on in Los Angeles County with varying combinations of case loads at each of the three steps in the job. The outcome in terms of specific units indicates that a good initial interview is the most important. The case load of the "qualifier" should be kept low. The load on the "field intake" group could be stepped up. The load on the "carrier" should not be overdone.

These differences talk in dollars. In terms of total expense per 100 original applications there is a range from \$11,000 to \$15,000, depending on what combinations of load are placed on the three groups.

Administrative research of this kind has application in the field of public health. Public health nursing, sanitary and food inspection are suitable fields. At what point do checking and supervision yield returns disproportionate to the cost? This is a matter worth exploration.

GEORGE T. PALMER

Everyday Nursing for the Everyday Home—By Elinor E. Norlin, R.N., and Bessie Donaldson, R.N. New York: Macmillan, 1942. 306 pp. Price, \$2.50.

Everyday Nursing for the Everyday Home is a very attractive title for a very timely and practical presentation of knowledge and skills of especial value to all families and home builders today. The authors are registered nurses with long and varied experience in private duty, hospitals, and public health nursing. For some years they have been teaching home nursing and health in the New York City high schools. At the request of the New York City Board of Education, they prepared a syllabus on home nursing and their book is based on this syllabus.

The book is divided into two parts. The first, approximately half of the total, deals with Nursing to Keep Well,

the second, with *Nursing When Illness Comes*. The material is presented in a very readable style and is supplemented by very simple and clear drawings and illustrations. The volume includes an excellent list of suggested readings of interest to any home maker and a splendid glossary is included.

It would seem to the reviewer that this publication will be of definite interest to home makers and to all students and teachers of home nursing.

MARION G. HOWELL

Eye Hazards in Industry—By *Louis Resnick*. Published for the *National Society for the Prevention of Blindness*. New York: *Columbia University Press*, 1941. 239 pp. Price, \$3.50.

The appearance of this book is timely in view of the increase in injuries due to industrial accidents during the last two years reported by such authorities as the Bureau of Labor Statistics and the National Safety Council. The book is divided into two parts: Part I poses the problem which is essentially the protection of the eyes of industrial workers from injury; Part II proposes ways and means to solve the problem.

In Part I are presented the facts concerning the nature and incidence of industrial eye injuries and their cost to the employer, employee, and the community.

In Part II the author presents most effectively a practical manual for the control of eye hazards in industry. Mechanical guards, goggles, and protective devices of different types are illustrated and explained. The rôle of process revision, education of employer and employee, and illumination of working stations in the prevention of visual injury is clearly set forth in succeeding chapters. The text closes with a brief outline of the importance and need of administrative supervision in the conservation of eyesight in industry.

The reviewer is impressed with the aims of the book and the fact that it is unique in the field. It is intended primarily for safety engineers, safety inspectors and others directly engaged in safety work concerned with conservation of vision. The author makes his fundamental point with the introductory statement that 300,000 eye injuries occur in American industries yearly, costing employers more than \$100,000,000 and injured workmen and their communities annually an equal sum. All but 2 per cent of this enormous economic loss with attendant physical disability and suffering is said to be wholly unnecessary.

As a whole the book is excellent and should be put into the hands of everyone in industry whose duties are in any way concerned with health and safety. The admirable chapters on preventive measures merit reproduction in cheaper form for distribution to small industrial plants where such material is most needed and where it may not otherwise penetrate.

BENJAMIN F. JONES

Gynecology and Female Endocrinology—By *Emil Novak, M.D., D.Sc. (Hon. Dublin), F.A.C.S.* Boston: *Little, Brown*, 1941. 605 pp. Price, \$10.00.

The author approaches his text with the viewpoint that gynecology is no longer to be considered as a branch of surgery inasmuch as the biologic aspects are so prominent. He thus omits operation details. The diagnosis and treatment are stressed from both anatomic-physiologic approaches. In his consideration of this field he attempts to limit his discussion to "straight" gynecology and female endocrinology. The latter may be a little confusing as the line of demarcation between male and female endocrinology is by no means clear.

The arrangement of material follows the stereotyped form common to most

texts. The chapter on anatomy presents nothing new. The discussion of history taking and physical examination is good and, of course, stresses the gynecologic viewpoint. The importance of a general study of the patient might have received more emphasis though it is brought out with reference to endocrinopathies. The anatomic grouping of diseases is endorsed rather than the recognition of disease processes which are now located here and again there.

The author manifests a wide familiarity with the literature, especially in the fields of pathology and endocrinology, and is perhaps inclined to be discursive. The illustrations are excellent and the author and publisher may well contemplate this work as a production worthy of them. In such a kaleidoscopic field as endocrinology is at present, it is not possible to have a book published which is up to the minute in all details. One who reads and studies this work could not help attain basic and clinical knowledge of great value.

FRED L. ADAIR

Mental Hygiene for Community Nursing—By Eric Kent Clarke, M.D. Minneapolis: University of Minnesota Press, 1942. 262 pp. Price, \$3.50.

In twelve chapters Dr. Clarke beautifully develops the thesis that each one's reaction to illness (and many times the illness itself) is but a natural part of his total life pattern, and that the community nurse is in the strategic position to give real help. The book is full of short case histories which commend themselves particularly as being "run of the mill" patients whom the nurse sees from day to day. The reviewer cannot remember another psychiatric product that is so nicely tuned to the group for whom it is written. Some of

the terms are pretty complicated for the amateur—but could not have been more adequately described without unjust lengthening of the text.

Everyone who reads the book must develop an interest in the *why* of the crankiness, the unreasonableness, the faith or hope of her patients. And that is at least half of the trick.

The book covers habit problems and many of the usual ones of the school child; it goes over the more common family conflicts; there is an excellent chapter on convalescents; the adolescent and the handicapped child each has a good chapter. The psychoneurotic is as hard to deal with in the book as in life—but Dr. Clarke sets up a clear picture of our limitations here. The chapter on what the community nurse can do for the psychotic and his family, is peculiarly good.

All in all, an excellent tilling of a new field by a man who knows his business.

JAMES S. PLANT

Food Values of Portions Commonly Used—By Anna de Planter Bowes and Charles F. Church. (4th ed.) Philadelphia (311 So. Juniper Street): Anna de Planter Bowes, 1942. 35 pp. Price, \$1.00.

This is the fourth edition of a well known manual which has been widely used by people who wish to have an easy reference book. The calculations have been brought up to date and include a table by the National Research Council, Committee on Foods and Nutrition. The tables are attractively put together and as usual make it quite easy to evaluate the actual intake in the usual dietary. It would be found useful by students in medicine, dentistry, public health, nursing and nutrition.

LEONA BAUMGARTNER

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Manifestations of Malnutrition—

As evidence that malnutrition among Americans is conspicuous by its absence, Clendening has reported that in his 10 years' experience at the Kansas City General only 3 cases of pellagra were seen. Well, here is a study made in comparable Ohio hospitals indicating that from 1 to 2 per cent of all medical admissions are pellagrins, and that the true incidence of pellagra, like other deficiency states, is underestimated.

BEAN, W. B., *et al.* The Incidence of Pellagra in Ohio Hospitals. J.A.M.A. 118, 14:1176 (Apr. 4), 1942.

Schaeffer Method vs. Mechanical Resuscitation—In these days when thousands are being taught the rudiments of first aid, any article on resuscitation is of wide interest. This one is a report of laboratory studies which indicate that rhythmic inflation and suction is definitely superior to manual artificial respiration, or rhythmic inflation.

BIRNBAUM, G. L., and THOMPSON, S. A. Resuscitation in Advanced Asphyxia. J.A.M.A. 118, 16:1364 (Apr. 18), 1942.

Full Report on Sister Kenny's Treatment—Observers who have seen poliomyelitis patients treated by the Kenny method are convinced that they are better off in (a) comfort, (b) freedom from deformity, (c) rapidity and extent of recovery, than are patients treated by conventional methods. This detailed report should be studied by all who may have any relationship whatever to the problem of polio control.

DALY, M. M. I., *et al.* The Early Treatment of Poliomyelitis. J.A.M.A. 118, 17:1428 (Apr. 25), 1942.

Xerosis Conjunctivae, *et al.*—

Preclinical nutritional deficiency states as represented in tissue depletion, biochemical lesions, and altered physiology are more common and more important than the frank manifestations of nutritional failure. It is the early manifestations that public health and private physicians must understand in order that they may play their proper parts in the national campaign for better nutrition. This is a paper of immediate importance to all.

JOLLIFFE, N. Nutritional Failures: Their Causes and Prevention. Milbank Quart. 20, 2:103 (Apr.), 1942.

Tuberculosis Takes on New Seriousness—A negative tuberculin reaction is preferable in a non-tuberculized environment, a positive one in a tuberculized community. Primary and reinfection types of tuberculosis cannot be told apart for each may have certain features of the other. Hence, all newly discovered x-ray lesions must be treated as potential phthisis. These provocative answers to a series of pertinent questions on the epidemiology of tuberculosis, and their interpretations should be read by all.

MAYER, E., and RAPPAPORT, I. Present Key Problems in Tuberculosis. J.A.M.A. 118, 14:1179 (Apr. 4), 1942.

What Four Cents Will Buy—

Four cents per capita was spent for venereal disease control in 1940. That is a sizable sum and for it we were

and still are getting a lot of syphilis prevention. How it was carried out in the several states is the gist of the excellent study.

MOUNTIN, J. W., and FLOOK, E. Distribution of Health Services in the Structure of State Government. *Pub. Health Rep.* 57, 16:553 (Apr. 17), 1942.

Some Populations Are Phoenix-like—America's population is fast approaching stationariness, city growth is slowing down, poorer classes multiply at greater rates than the well-to-do, the old age segment is greatly increasing. These four obvious phenomena affect almost every aspect of personal, social, and national life. The discussion paints a darksome picture, with just a ray of hope the value of which you may want to assess.

PANUNZIO, C. Population Trends in the United States. *Sci. Month.* 54, 4:353 (Apr.), 1942.

All the Resources of Two Americas—Nazis know the correlation between good nutrition and qualities of courage, stamina, and morale. They are applying it to the hilt, in reverse, to establish and maintain the repulsive Nazi dichotomy—slave caste and master race. America's task in defeating this design and healing the wounds of starvation when the war is won is portrayed in the most eloquent state paper these tired eyes have had the privilege to see.

PAPPAN, T. Health Nutrition, and National Defense. *Canad. Pub. Health J.* 33, 3:99 (Mar.), 1942.

Confidential Death Certificates—Because so many people may see the death certificate between the time it is made out (in one Canadian Province) and the time it reaches the statistical offices of the Ministry of Health, a confidential death certificate is now in use. It is provided with a

sealable flap to cover the cause of death. There is evidence that a more accurate reporting of the cause of death has ensued since the change was made. About one in five were intentionally falsified or incomplete under the old system.

PARROT, P. The Use of the Confidential Death Certificate in the Province of Quebec. *Canad. Pub. Health J.* 33, 3:114 (Mar.), 1942.

Building Malaria Out—Experience in lining drainage ditches with monolithic concrete, pre-formed slabs and bricks is recounted.

ROBERTSON, J. L. Observations on Experimental Malaria Control Drainage Ditch Linings. *Pub. Health Rep.* 57, 13:451 (Mar. 27), 1942.

Draftees in Two World Wars—Syphilis, tuberculosis, mental disqualifications now are weeded out by modern diagnostic methods that were not available for use in the First World War draft. Then it was necessary to secure men quickly, train them hurriedly, transport them without loss of time. Now we are building an efficient army that can handle complicated equipment and we are wisely choosing the best men to do it.

ROWNTREE, L. G., *et al.* Health of Selective Service Registrants. *J.A.M.A.* 118, 14:1223 (Apr. 4), 1942.

Respiratory Cross Infections Can Be Prevented—Individual air conditioning of cubicles did not prevent respiratory infections in an infants' ward, but air conditioning with germicidal light barriers or glass barriers did prevent cross infections. Maintenance of light barriers is costly, the use of glass partitions a nuisance, and the installation expensive. So you take your choice.

SAUER, L. W., *et al.* Control of Cross Infections of the Respiratory Tract. *J.A.M.A.* 118, 5:1270 (Apr. 11), 1942.

TB in the Dark—Dried tubercle bacilli, depending upon the mass of the dose, survived in ordinary room light up to 5 days. In the dark some survived $3\frac{1}{2}$ to 5 months. In the refrigerator they lived even longer. They lived longer in winter than in other seasons.

SMITH, C. R. Survival of Tubercle Bacilli. *Am. Rev. Tuberc.* 45, 3:334 (Mar.), 1942.

Fluorides in the Water, Minerals in the Diet—In a Texas county the incidence of caries is half the lowest

reported elsewhere and much below the average. Either the consumption of water containing fluorine or its application during cleansing, or both, must have been a contributory factor. Also there is a high phosphorus content to vegetable and animal products produced in the region. The incidence of caries was directly proportionate to *Lactobacillus acidophilus* in the saliva.

TAYLOR, E. Preliminary Studies on Caries Immunity in the Deaf Smith County (Texas) Area. *J. Am. Dental Assoc.* 29, 3:438 (Mar.), 1942.

ASSOCIATION NEWS

SEVENTY-FIRST ANNUAL MEETING

ST. LOUIS, MO., OCTOBER 27-30, 1942

Headquarters

MUNICIPAL AUDITORIUM

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Robert Dessent, M.D., 527 N. Main St., Ann Arbor, Mich., Student, Univ. of Michigan, School of Public Health
Henry W. Kassel, M.D., City Hall, Kansas City, Kan., Asst. Director of Health
James C. Malcolm, M.D., 1501 W. Main St., Visalia, Calif., Asst. Surgeon (R), U. S. Public Health Service
Jason Miller, M.D., Hinds County Health Dept., Jackson, Miss., Asst. Surgeon (R), U. S. Public Health Service
Willard D. Nalchajian, M.D., 5 Nichols, Chelsea, Mass., Student, Dept. of Biology and Public Health, Massachusetts Institute of Technology
C. Barton Nelson, M.D., M.P.H., 2808-42nd Ave., South, Minneapolis, Minn., Epidemiologist, State Dept. of Health
Joseph A. Randazzo, M.D., Municipal Bldg., 55 Front St., Bath, Me., Passed Asst. Surgeon (R), U. S. Public Health Service
Carl J. Weissmann, M.D., P. O. Box 731, Waynesville, Mo., Asst. Surgeon (R), U. S. Public Health Service
Henry S. Wolanczyk, M.D., Lebanon, Mo., Health Officer, Laclede County Health Dept.
Rhea L. Wyatt, M.D., Clarke-Wayne Health Dept., Shubuta, Miss., Director

Laboratory Section

Ruth S. Bitter, 109 Harvard Terrace, San Antonio, Tex., Laboratory Technician, City Health Dept.
Leo Cravitz, B.S., 114 Irving St., Everett, Mass., Student, Dept. of Biology and Public Health, Massachusetts Institute of Technology

Marian Glater, B.S., 53 Sharon St., Hartford, Conn., Microbiologist, State Board of Health Laboratory
Jeanette Herman, B.S., 10 Longwood Terrace, Boston, Mass., Graduate Student in Public Health, Massachusetts Institute of Technology
Justina H. Hill, D.Sc., Calvert Court, Baltimore, Md., Assoc. in Urology, Johns Hopkins Medical School
Harold A. Johnson, 5229 Columbus Ave., Minneapolis, Minn., Student, Univ. of Minnesota
Eugene V. LaClair, B.A., Keizer Hospital, North Bend, Ore., Director of Laboratory
Lotte M. Lisman, City Health Dept., Danville, Va., Technician in charge of Laboratory
Perry J. Manheims, M.D., 27 West 96th St., New York, N. Y., Asst. Director, Laboratory of Lenox Hill Hospital
Francis M. Middleton, B.S., U. S. Public Health Service, E. 3rd and Kilgour, Cincinnati, Ohio, Asst. Chemist
Esther R. Mizl, 990 E. 17th St., Brooklyn, N. Y., Laboratory Asst., New York City Dept. of Health
Francis I. Norris, B.S., E. 3rd and Kilgour Sts., U. S. Public Health Service, Cincinnati, Ohio, Asst. Chemist
Warren B. Rawlings, V.M.D., Pitman-Moore Co., Zionsville, Ind., Asst. Director, Biological Laboratories
Edward Records, V.M.D., Univ. of Nevada, Reno, Nev., Director, State Veterinary Control Service
Mortimer Warren, M.D., Maine General Hospital, Portland, Me., Pathologist

Vital Statistics Section

- Oswald K. Sagen, Ph.D., Capitol Bldg., State Dept. of Public Health, Springfield, Ill., Chief Statistician
 Melville A. Taff, Jr., B.S., 111 Berman Court, Chapel Hill, N. C., Student, Univ. of North Carolina

Engineering Section

- Major Charles L. Adams, M.S., 85 Ann Ave., Battle Creek, Mich., Asst. Post Medical Inspector, U. S. Army
 John A. Brown, B.S., 30 East Columbia, Colorado Springs, Colo., Sanitarian, City-County Health Unit
 James J. Corbalis, Jr., B.C.E., Fairfax County Health Dept., Fairfax, Va., Sanitation Officer
 Herman L. Fellton, B.S., 66 Luckie St., U. S. Public Health Service, Atlanta, Ga., Passed Asst. Sanitary Engineer
 Fred E. Johnston, 220 Cloverhurst Ave., Athens, Ga., Public Health Engineer, Athens and Clarke County Dept. of Health
 Silvio D. Mastroianni, A.B., 728 W. 5th St., Reno, Nev., Sanitary Inspector, State Board of Health
 Frank B. Maxson, B.S.C.E., State Health Dept., Cheyenne, Wyo., Asst. Sanitary Engineer
 Albert W. Petty, B.S., 317-34th St., Virginia Beach, Va., Sanitation Officer, State Dept. of Health and Town Engineer
 Arthur C. Ragsdale, M.S., Eckles Hall, Columbia, Mo., Professor of Dairy Husbandry, Univ. of Missouri
 Joseph A. Salvato, Jr., M.C.E., 35 Market St., State Dept. of Health, Poughkeepsie, N. Y., Asst. District Engineer
 Milo R. Simmonds, B.S., P. O. Box 462, Antlers, Okla., Asst. Sanitary Engineer, State Health Dept.
 George E. Weant, Jr., B.C.E., 130 Maupin Ave., Salisbury, N. C., Junior Public Health Engineer, U. S. Public Health Service.

Maternal and Child Health Section

- Dorothy A. Hansen, R.N., Box 337, Sitka, Alaska, Public Health Nurse, Territorial Dept. of Health
 H. Close Hesseltine, M.D., 5848 Drexel Ave., Chicago, Ill., Asst. Professor of Obstetrics and Gynecology, Univ. of Chicago
 Dr. Julie Palmieri, Morse St., Arroyo, Puerto Rico, Physician, Bureau of Maternal and Infant Hygiene, Puerto Rico Health Dept.
 Benjamin Sachs, M.D., M.S.P.H., 30-24 Steinway St., Astoria, N. Y., Student, DeLamar Institute of Public Health

Industrial Hygiene Section

- Orlen J. Johnson, M.D., M.P.H., 535 N. Dearborn, Chicago, Ill., Field Worker, Council on Industrial Health, American Medical Assn.
 Richard W. Schayer, B.S., State Board of Health, Jefferson City, Mo., Asst. Chemist, Div. of Industrial Hygiene, U. S. Public Health Service

Food and Nutrition Section

- Edith M. Cushman, M.P.H., 434 Edgewood Ave., New Haven, Conn., State-wide School Lunch Supervisor, WPA
 Bryce Prindle, Ph.D., Iowa State College, Dept. of Bacteriology, Ames, Iowa, Teacher of Bacteriology
 Frederick J. Stare, M.D., Barnes Hospital, 600 S. Kingshighway, St. Louis, Mo., Resident Physician

Public Health Education Section

- Cornelius M. Bowen, 36 Bogert Place, Westwood, N. J., Health Officer
 Elizabeth E. Harvey, M.S.P.H., 935 Bonifant St., Silver Spring, Md., Health Educator
 Clarence L. E. Monroe, Ph.D., 1613 W. Butler St., Philadelphia, Pa., Teacher of Hygiene, Morgan State College
 Edwin S. Powell, State Board of Health, Columbia, S. C., Field Agent, Venereal Disease Control
 Lillian B. Rumbaugh, B.A., 984 University Terrace, Reno, Nev., Secretary, State Hygienic Laboratory and Div. of Venereal Disease Control, State Health Dept.
 Clarence G. Salsbury, M.D., Sage Memorial Hospital, Ganado, Ariz., Medical Director and Chief Surgeon

Public Health Nursing Section

- Thelma C. Ballard, Carroll County Health Dept., Huntingdon, Tenn., Junior Public Health Nurse
 Edna Burke, 1003 Carona St., Denver, Colo., Asst. Supt., Denver Visiting Nurse Assn.
 Ina M. Collins, R.N., Jasper County Health Dept., Webb City, Mo., Senior Staff Nurse
 Lucille E. Corcoran, R.N., B.S., 845 Johnson Ave., Monterey, Calif., Public Health Nurse, U. S. Public Health Service
 Beulah R. Daniel, R.N., F-5 Terrace Apts., Macon, Ga., Crawford County Public Health Nurse
 Audrey R. Gallion, R.N., B.S.N., 1215 N.E. 4th St., Fort Lauderdale, Fla., Supervising Nurse, Florida Migratory Labor Health Assn.
 Eileen M. Goodall, R.N., Box 942, 921 S. 4th St., Laramie, Wyo., County Public Health Nurse

Marjorie Kennedy, B.S., Lowndes County Health Dept., Columbus, Miss., Public Health Nurse, U. S. Public Health Service
 Edna Kupferschmidt, R.N., City Hall, Div. of School Nursing, Dubuque, Iowa, City Nurse

Margaret Mallett, R.N., 6725 Harding Ave., Miami Beach, Fla., Public Health Nurse, Florida Migratory Labor Health Assn.

Mary E. McAuliffe, R.N., 305 Greenwood, Topeka, Kan., State Supervisory Nurse, State Board of Health

Edythe E. Payne, Reserve, N. M., Public Health Nurse, U. S. Children's Bureau

Mary A. Preston, B.S., Box 1500, Anchorage, Alaska, Junior Public Health Nurse, Anchorage Health Dept.

Elesa Simonson, R.N., B.N., Salmon, Ida., Lemhi County Nurse

Esther B. Smith, R.N., P. O. Box 732, Belle Glade, Fla., Visiting Nurse, Florida Migratory Labor Health Assn.

Anne M. Whalley, Box 1164, Kodiak, Alaska, Public Health Nurse, Territorial Dept. of Health

Epidemiology Section

Mabel S. Ingalls, Ph.D., Albany Medical College, New Scotland Ave., Albany, N. Y., Asst. Professor of Bacteriology

Nicholas Michelson, M.D., Jefferson County Health Dept., Birmingham, Ala., Surgeon (R), U. S. Public Health Service

Jose Rodriguez-Pastor, M.D., 8 Pershing St., Santurce, Puerto Rico, Chief, Bureau of Tuberculosis, Puerto Rico Health Dept.

Richard Scandalis, M.D., 116 Ferguson, Fallon, Nev., Field Physician, U. S. Indian Service

Unaffiliated

Karl W. Anderson, M.D., 430 Oak Grove St., Minneapolis, Minn., Chief Medical Officer, Northwestern National Life Insurance Co.

DECEASED MEMBERS

T. R. Crowder, M.D., Chicago, Ill., Elected Member 1905, Elected Fellow, 1922, Industrial Hygiene Section

M. Luise Diez, M.D., Boston, Mass., Elected Member 1926, Elected Fellow 1931, Maternal and Child Health Section

Clinton A. Kane, M.D., Elkton, Md., Elected Member 1926, Health Officers Section

Howard Morrow, M.D., San Francisco, Calif., Elected Member 1934, Health Officers Section

Henry G. Steinmetz, M.D., Lansing, Mich., Elected Member 1937, Health Officers Section

William H. Walsh, M.D., Chicago, Ill., Elected Member 1930, Industrial Hygiene Section

S. W. Wynne, M.D., New York, N. Y., Elected Member 1915, Elected Fellow 1924, Vital Statistics Section

CLOSING DATE FOR SUBMITTING FELLOWSHIP APPLICATIONS

MEMBERS who may be interested in applying for Fellowship in the A.P.H.A. are hereby advised that Fellowship applications should be received not later than August 1, to insure consideration at the 71st Annual Meeting.

WANTED: The following issues of the *American Journal of Public Health*—July and August, 1941; and January, 1942. The Association will be glad to pay postage.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

ARIZONA MERIT SYSTEM COUNCIL

The Merit System Council for the Arizona State Department of Social Security and Welfare and State Department of Health will probably shortly announce merit examinations for positions in those departments as follows:

State Director, Local Health Administration.....	\$350-400	
Director Maternal and Child Hygiene.....	350-400	
Director, Local Health Unit.....	350-400	and \$300-350
Health Officer-in-Training.....	300-350	
Director of Sanitary Engineering.....	300-350	
Sanitary Engineer	200-250	
Director, Public Health Laboratory.....	300-350	
Senior and Junior Bacteriologist-Serologist.....	165-215	and \$115-165 respectively
X-ray Technician	165-190	
Director Public Health Nursing.....	215-265	
Nursing Consultant, special fields.....	175-200	
Supervising Public Health Nurse, local unit....	175-200	
Senior and Junior Public Health Nurse, local unit	150-175	and \$125-150 respectively
Public Health Nurse-in-Training.....	100-125	
Director Health Education.....	215-265	
Nutrition Consultant	215-265	
Vital Statistician	175-225	
Medical Social Worker.....	165-190	
Child Welfare Consultant.....	200-250	

Competition is open on a nation-wide basis. Professional registration in Arizona required before appointment for certain classes. Closing date for receipt of applications will probably be about June 15.

Application blanks, information regarding qualification requirements, conditions governing filing of applications, and detailed descriptions of the various classes of positions may be secured from the Merit System Council, Room 208, Home Builders Building, Phoenix, Ariz.

GEORGIA STATE MERIT SYSTEM ADMINISTRATION

The Supervisor of Examinations of the Georgia State Welfare Department announces competitive examinations for filling positions in the Public Assistance, Crippled Children, and Child Welfare Divisions. In the Crippled Children Division the salary ranges are minimum \$1,800, maximum \$2,280 for the position of Medical Social Worker, Orthopedic Field Nurse, and Physical Therapy Technician; for District Orthopedic Field Nurse a minimum of \$1,920, maximum of \$2,400; Physical Therapy Consultant a minimum of \$2,400, maximum of \$2,880; Orthopedic Nursing Consultant and Medical Social Consultant begin at a minimum of \$2,700 and range to a maximum of \$3,180; Medical Director of the Crippled Children Services begin at a minimum of \$4,200 with a maximum of \$5,400.

All of these positions are open to competitive assembled examinations except the Medical Director of the Crippled Children Services which is an unassembled examination. The examinations are based upon a rating of training and experience, a written test, and an oral interview. Each eligible who is appointed from the adequate register will be required to serve a probational period of 6 months as is the usual custom in Civil Service and Merit System agencies.

Georgia State residence is not required of an applicant in order to participate in the above examinations.

U. S. CIVIL SERVICE COMMISSION

The Commission has announced unassembled examinations for Junior Public Health Nurse at \$1,800 a year and Junior Graduate Nurses at \$1,620 a year, under which the training and age requirements of announcements No. 88 and 103 of 1941 have been amended. Persons interested should communicate with the U. S. Civil Service Commission in Washington or obtain the amended announcements at any first or second class post office.

The Commission has announced that applications will be received for positions as Senior Medical Officer (\$4,600), Medical Officer (\$3,800), and Associate Medical Officer (\$3,200) for appointments in the Public Health Service, with the Food & Drug Administration, Veteran's Administration and the Indian Service. Forms for application may be obtained from the U. S. Civil Service Commission, Washington, D. C.

PHYSICIANS NEEDED IN CANAL ZONE

The U. S. Civil Service Commission announces an examination to secure physicians for clinical service in the Panama Canal Zone. Graduation from a class A medical school subsequent to May 1, 1920, is required, and the applicant must be under 50, 25 to 35 years of age preferred. Entrance salary \$4,000. Persons interested should communicate with the U. S. Civil Service Commission, Washington.

POSITIONS AVAILABLE

Physician with either public health training or experience in local health department administration to serve as health director in a county health department in mid-western state. Salary \$4,000 and \$500 travel (flat rate). Well established department with offices in attractive little city of 10,000. Write Box T, Employment Service, A.P.H.A.

Wanted: Trained Public Health Nurse, starting salary \$1,500 per year and traveling expense, increase to \$1,620 within 6 months. Saginaw County Health Dept., Saginaw, Mich.

Western state department of health will consider applications from physicians to fill four existing vacancies among county health officers, one vacancy in venereal disease control and positions as laboratory technicians. Write Box S, Employment Service, A.P.H.A.

County Public Health Nurses for New Mexico. Must have four months' post-graduate instruction under one of the recognized public health nursing courses and one year's experience. Must drive and have a car. Address inquiry to State Health Department, Santa Fe, N. M.

Position available—Deputy Commissioner of Health in mid-western city of 100,000. In writing give age, religion, training, experience and references. Write Box A, Employment Service, A.P.H.A.

PUBLIC HEALTH ENGINEER

Responsible professional public health engineering involving field investigations and office studies in the application of sanitary measures. The more difficult

engineering and sanitation field surveys include supervision over public water supplies, sewerage systems and sewage treatment plants and review of plans for same, and promotion and supervision of sanitation programs. Minimum qualifications: Training and experience equivalent to 3 years' civil engineering experience, including 2 years in public health or sanitary engineering; or completion of an academic year of graduate study and a year's experience in sanitary or public health engineering; and graduation from a college of recognized standing with a major course in civil or sanitary engineering. The salary range is \$205 to \$250 per month depending upon experience. Apply Box E, Employment Service, A.P.H.A.

OTHER VACANCIES

Southwestern state health department seeks 2 physicians for assignment to district health units, personally to conduct several small venereal disease clinics on a rotating schedule. Experience preferred but not required. Salary \$3,000, plus actual travel allowance not to exceed \$1,200. Write Box V, Employment Service, A.P.H.A.

The New Mexico State Department of Public Health will consider applications for the position of Assistant Director of the Maternal and Child Health Division. Address inquiries to the State Department of Public Health, Santa Fe, N. M.

Wanted: Trained Public Health Nurse, starting salary \$1,500 per year and traveling expenses. Increase may be expected within 6 months. Shiawassee County Health Department, Corunna, Mich.

Wanted: Nurse for county health work. Salary \$1,800 per year with travel allowance (additional) of \$500 per year. Address District Health Department 2, West Branch, Mich.

Instructor in Bacteriology, Medical School, large midwestern university, M.D. (or Ph.D. or D.Sc. in Bacteriology); Male. Salary \$1,800 to \$2,500 according to age and experience. Write Box D, Employment Service, A.P.H.A.

POSITIONS WANTED

ADMINISTRATIVE

Teaching or administrative position desired by physician, aged 48. Experienced teacher in preventive medicine and public health, now employed at prominent medical school; 20 years' experience in municipal health administration and epidemiology. A-491

Physician, B.S., M.D., and M.S.P.H., University of Michigan, aged 35, experienced city-county health administration and as director university student health service. Will consider permanent responsible position offering good income. A-492

Physician, aged 28; M.D. Rush; M.P.H. Harvard; seeks administrative position under first class supervision. A-496

WOMEN PHYSICIANS TRAINED IN PUBLIC HEALTH

Woman aged 34, M.D., University of Basle, Switzerland, M.S.P.H. DeLamar Institute, Columbia University. U. S. citizen. Excellent references. Especially interested in industrial hygiene. A-493

Woman aged 41, M.D. Columbia University, M.S.P.H. DeLamar Institute, experienced in epidemiology and research, seeks position offering administrative experience. A-494

Woman physician, aged 48, M.D., University of Vienna. Excellent European pediatric experience. Seeks position in pediatrics, administration or statistical research. A-495

HEALTH EDUCATION

Teacher and research worker, man, Ph.D., age 52. Extensive record as college professor of biology and hygiene and investigator, for the past two years engaged in research. H-499

Health Educator, Negro, man with background of High School administration and M.S.P.H. from University of Michigan, seeks position in Health Education. Public agency or educational field. Excellent references. H-497

Health Educator, M.A. in Education, 10 years' background in community organi-

zation for public health education, also teaching of personal and community health at high school and college levels. Public health nurse, able to teach mental and social hygiene as well as general health education. East preferred. H-498

Health Educator. Man with M.S. in preventive medicine and public health. Negro. Seeks position in Health Education or field work with official or non-official agency. H-500

Woman with master's degree in health education, 12 years' successful experience in public school and college teaching, administration and research. Will consider position in normal school, public schools, or in official or nonofficial health agencies. Prefers South or East. Available at once. H-501

LABORATORY

Milk Sanitarian and Technologist, age 37, Ph.D., Bacteriology, Wisconsin, 10 years' experience in milk and food sanitation from industrial and official angle, seeks administrative position with opportunity for research or investigational work preferred. L-381

Chemist, Sc.D., Biochemistry, Johns Hopkins University. Age 31. Public health laboratory experience, teaching experience. Desires position with promise of advancement, preferably in commercial organization. L-461

Bacteriologist, young man 28, with B.S. in industrial science, experienced in newspaper work, salesmanship and now employed in state department of health laboratory, seeks position as bacteriologist or doing promotional work of public health nature. L-465

Bacteriologist, Ph.D. Teaching and laboratory experience in public health laboratory methods. Desires position with University, city or state health laboratory. L-466

MISCELLANEOUS

Well trained ophthalmologist desires position in public health work. M-450

Advertisement

Situations Wanted

BACTERIOLOGIST—A.B., Ph.D., state university; 6 years, university laboratory of animal pathology; 4 years, parasitologist, state department public health. PH6-1, Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago.

NURSE—A.B. degree eastern college; graduate of school of nursing of university hospital; year's postgraduate training in public health nursing; is certified; nearly 15 years' executive experience in public health nursing; past several years, executive secretary, city health council; very superior woman

of broad and varied experience; has made distinct contribution to field of public health nursing. PH6-3, Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago.

PUBLIC HEALTH PHYSICIAN—Degrees from leading schools; several years, field worker, well known foundation; 6 years, successful administrative experience; 8 years, health officer, large city in the South; will go anywhere. PH6-2, Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago.

Opportunities Available

WANTED—INDUSTRIAL HYGIENIST—Man with medical degree preferred but not required; new plant; staff consists of eight physicians and a complement of forty technicians, nurses, etc.; Mid-South. PH6-4, Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago.

WANTED—(a) City physician; full-time appointment in midwestern town of 25,000; woman physician eligible; \$4,000. (b) Women physicians; public health appointment, pediatric background desirable; considerable traveling; Midwest. (c) Student health physician; young women's college; should be well qualified internal medicine and diagnoses; Midwest; immediately. (d) Health Commissioner, town of 105,000; Midwest. (e) Pediatrician; state public health staff, Midsouth. (f) Director; department of health and physical education; midwestern metropolis; excellent con-

nections. (g) Obstetrician and pediatrician for consultant appointments; state department of health; public health experience desirable but not required; women eligible. PH6-5, Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago.

PUBLIC HEALTH NURSES—(a) Instructor and supervisor of public health and outpatient nursing service; department averages 12,000 patients monthly; duties teaching and administrative; degree required; large university hospital; West Coast. (b) School nurse for public schools in small city located in Chicago area; appointee must have car; minimum salary, \$150. (c) Student health nurse; girls' school located in Southern city; 9 months' appointment; \$1,300, maintenance. PH6-6, Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago.

NEWS FROM THE FIELD

THE TEACHING OF PUBLIC HEALTH AND PREVENTIVE MEDICINE TO MEDICAL STUDENTS

HARRY S. MUSTARD, M.D., Chairman of a Committee on the Teaching of Public Health and Preventive Medicine of the Association of American Medical Colleges, recently presented a report for the information of the Committee on Professional Education of the American Public Health Association. The report is published in the March issue of the *Journal of the Association of American Medical Colleges*.

This committee was appointed originally at the suggestion of the A.P.H.A. Committee on Professional Education as a liaison between its Subcommittee on the Education of Medical Undergraduates, of which W. G. Smillie, M.D., is Chairman, and the Association of American Medical Colleges. The report summarizes findings and conclusions based on a questionnaire and opinions of the committee members, all of which will be discussed at the October meeting of the Association of American Medical Colleges.

Pointing to the wide diversity of opinion as to what should be included in a course of preventive medicine, the committee points out that this is relatively a new undertaking which faces an already overcrowded and not entirely elastic curriculum.

Believing that confusion in the terms "preventive medicine" and "public health" should be overcome, it is recommended that preventive medicine be regarded as that body of knowledge and those practices believed to contribute to the maintenance of health and the prevention of disease in either the individual or the aggregate. Correspondingly, public health is to be

regarded as that body of knowledge and those practices believed to contribute to health in the aggregate, either through preventive or corrective measures or both.

The committee records a striking increase in the number of full-time departments since 1935-1936 when FitzGerald classified 24 medical schools, 18 in the United States and 6 in Canada, as having such departments. There are now 32 full-time departments, 27 in the United States, 5 in Canada.

In 26 medical schools the committee finds that there are combined departments and that 13 schools have separate but not full-time departments.

The committee deprecates the tendency among instructors in preventive medicine and public health to visualize students as future health officers rather than as private practitioners of medicine interested and informed but not specializing in this subject.

The report continues:

That, regardless of extremes of radical and conservative opinion as to how the future of medicine may best be shaped, it be recognized that the demands of an enlarging public medical service, under one arrangement or another, will draw a much greater proportion of physicians than heretofore into government employment, on full-time, part-time, or fee basis, thus making them increasingly responsible for participating in organized preventive and corrective measures in the interest of the public health.

That it be recognized that qualifications for productive teaching in public health or for instruction in the mass aspects of preventive medicine are not likely to be acquired through training and experience in some other field of medicine, or to arise naturally as part of the ageing process.

That although it is entirely possible, in view of individual competence and personality, to utilize the part-time services of a health officer to direct a teaching department of public health, this should not be

regarded as a desirable procedure in ordinary circumstances.

That there continue in force the previously accepted standard of this Association, which sets aside for the teaching schedule of the department of preventive medicine and public health, 4 per cent of total curriculum hours available; that because in teaching preventive medicine and public health only minor use may be made of low salaried assistants and instructors, the budget for such a department should range from 5 to 8 per cent of the total instruction budget of the medical school.

Other members of the committee beside Dr. Mustard are John E. Gordon, M.D., Hugh R. Leavell, M.D., and Charles E. Smith, M.D.

NUTRITION FOUNDATION NAMES ADVISORY COMMITTEES

THE Nutrition Foundation, New York, N. Y., which has been organized by fifteen food manufacturers to study nutrition for the improvement of public health, has announced the membership of the scientific advisory committee. Included with this group are: F. G. Boudreau, M.D., New York; C. A. Elvehjem, Ph.D., Madison, Wis.; Icie M. Hoobler, Ph.D., Detroit, Mich.; P. E. Howe, M.D., U. S. Army, Washington, D. C.; E. V. McCollum, Ph.D., Baltimore, Md.; Lydia J. Roberts, Ph.D., Chicago; W. H. Sebrell, M.D., Washington, D. C.; Henry C. Sherman, Ph.D., New York, N. Y.; F. F. Tisdall, M.D., Toronto, Ont.; R. R. Williams, Ph.D., New York, N. Y.

Among the members of the food industries advisory committee are: Frederick C. Blanck, Ph.D., Pittsburgh, Pa., and James A. Tobey, Dr.P.H., New York, N. Y.

MICHIGAN COMMITTEE ON COMMUNICABLE DISEASE CONTROL

A COMMITTEE has been appointed, by Dr. Henry Allen Moyer, of Lansing, Michigan State Health Commissioner, to study the needs for the

control of communicable disease which have arisen as the result of the sudden influx of defense workers in certain areas of the state, particularly where no organized health department exists. Members of the committee are:

Frank Van Schoick, M.D., of Jackson—Representing the state medical society

Eldred V. Thichoff, M.D., of Lansing—Representing the State Department of Health

Edgar E. Martmer, M.D., of Detroit—Representing the Michigan branch of the American Academy of Pediatrics

Lena Schermann, R.N., of Mason—Representing the Michigan State Nurses Association

G. Robert Koopman, of Lansing—Representing the Michigan Department of Public Instruction.

COUNCIL FOR EXPECTANT FATHERS

THE New Haven, Conn., Father's Council, sponsored by the local health department, marked its 5th anniversary on March 28 with the opening of the 11th series of meetings for expectant fathers. More than 400 men have attended these lectures during the past 5 years. On May 4 there was a joint meeting for fathers and mothers as part of the observance of National Child Health Week. Dr. Arnold Gesell, Professor of Child Hygiene and Director of the Clinic of Child Development at Yale University School of Medicine, New Haven, was the speaker.

FEWER AGENCIES REQUIRED

SPEAKING recently in Washington, Paul V. McNutt, Federal Security Administrator, said:

I believe it is sound public administration to work through the fewest agencies possible. If, however, there is an urgent task to do and no old line agency is willing or prepared to do it, the only alternative is to set up a new agency. Behind the recent multiplication of governmental agencies is a long history of official and neglected opportunities. I believe there are many lessons in this history which existing health agencies might well consider and in the light of which they might reconstruct their basic philosophy.

PAN AMERICAN CHILD CONGRESS DELEGATES FROM UNITED STATES

ON May 1, President Roosevelt designated eleven delegates representing the United States for the Eighth Pan American Child Congress, May 2 to 9 in Washington.

Headed by Katharine Lenroot, Chief of the Children's Bureau, as chairman, the United States delegation includes Dr. Frank G. Boudreau and the Right Rev. Mgr. Bryant J. McEntegart of New York; Jane M. Hoey, Dr. Edward O. Ernst, Bess Goodykontz, William G. Carr, Dr. M. O. Bousfield, Dr. Henry F. Helmholtz, Maria Pintado Rahn of the University of Puerto Rico, and Dr. Felix J. Underwood.

MALARIA CONTROL ACTIVITIES IN FLORIDA

FLORIDA has been designated a proving ground for the southeastern states in a national defense plan for malaria mosquito control activities. Leon County has been appointed for the trial defense malaria unit and U. S. Public Health officials in Atlanta, Ga., will collaborate. Dr. John E. Elmen-dorf, Jr., Pensacola, Director of the Bureau of Malaria Control, Florida State Board of Health, will supervise this program.

NATIONAL MATERNAL AND CHILD HEALTH COUNCIL SUSPENDS

BECAUSE of the lack of funds, it has been decided to wind up business and close the books of the National Maternal and Child Health Council (formerly National Council for Mothers and Babies), Washington, D. C., though the Council will continue as a corporation for the present, according to Mrs. Nathan Straus, Chairman of the Executive Committee.

Reporting that an effort to finance the Council through contributions from its constituent members had failed, Mrs.

Straus indicated that support from foundations was not assured and that for the present at least member agencies will themselves have to coördinate maternal and child health activities, and to bring help to desperately needy areas in the United States without the benefit of the Council.

U. S. PUBLIC HEALTH SERVICE MOVES ITS OFFICES

DURING March the headquarters of the U. S. Public Health Service on Constitution Avenue, Washington, across from the Munitions and Navy Buildings, was vacated by the Service which is now quartered in the old Naval Hospital at 23rd and E Streets.

Into the vacated building has moved the High Command of the United Nations.

NEW OFFICERS OF THE CONNECTICUT PUBLIC HEALTH ASSOCIATION

AT its recent Annual Meeting the Connecticut Public Health Association elected the following new officers:

President—Paul H. Brown, M.D., Stamford, Conn.

President-elect—Alfred L. Burgdorf, M.D., Hartford, Conn.

Vice-President—M. L. Palmieri, M.D., Middletown, Conn.

Secretary-Treasurer—Clement F. Batelli, M.D., New Haven, Conn.

Representative to the Governing Council of the A.P.H.A.—Joseph I. Linde, M.D., New Haven, Conn.

Alternative Representative to the Governing Council of the A.P.H.A.—Millard Knowlton, M.D., Hartford, Conn.

AMERICAN PHYSIOTHERAPY ASSOCIATION

THE American Physiotherapy Association has announced a conference to be held at Lake Geneva, Wis., June 28 through July 3 at which all organizations interested in physiotherapy will be asked to map their common problems and share in their solution.

Don W. Gudakunst, M.D., Medical Director of the National Foundation for Infantile Paralysis, Inc., New York, N. Y., has been designated A.P.H.A. representative to attend this conference.

NEW HEALTH UNITS IN NEBRASKA

THE Nebraska State Department of Health has established 3 new health units in defense areas: Cass-Sarpy County; Douglas County, including the city of Omaha; and Dodge-Saunders County. These units are established in connection with either army or defense production, and the personnel consists of medical officer, engineer, sanitarian, and 6 nurses.

PERSONALS

Central States

PALMER O. EICHER, M.D., of Decatur, Ill., has been named Health Officer of Adams County.

CAREY P. McCORD, M.D.,* of Detroit, Mich., has been elected to extramural lectureship on occupational diseases at the new School of Public Health of the University of Michigan, Ann Arbor.

LEONARD R. MARTI, B.S., M.Ed., formerly State Health Administrative Officer for the National Youth Administration in North Dakota, has been appointed Acting Director of the Division of Health Education for the North Dakota State Department of Health, during the leave of absence of WILLIAM ROEMMICH, B.S., M.S., who is attending school at the Massachusetts Institute of Technology.

LAURA K. McCrory, Ph.B., who has been associate state director, Farm Security Administration for North Dakota, has been appointed Con-

sultant Nutritionist of the North Dakota State Department of Health. GEORGE F. MOENCH, M.D.,† of Marshall, has been appointed Director of the Calhoun County Health Department, Marshall, Mich., succeeding HUGH B. ROBINS, M.D., who is on leave for graduate work at the University of Michigan School of Hygiene and Public Health. Dr. Moench was formerly Director of the Delaware County Health Department, Delaware, Ohio.

JESSE E. NIXON, M.D., of Portland, Ind., has been named Health Officer of Jay County.

ROY OXENDALE, formerly Topeka representative of the United Press, has been appointed Director of a new unit established by the Kansas State Board of Health, Topeka Kans. This Division on Public Health Information plans to extend lay educational programs pertaining to exhibits, movies, pamphlets, news releases and radio programs on public health.

CHARLES F. PECTOR, M.D., of Spencer, Ind., has been named Health Officer of Owen County.

IRA E. PERRY, of North Manchester, Ind., has been reappointed as Health Officer of Wabash County.

WALLACE S. PETTY, M.D.,* formerly head of the Sioux City and Woodbury County, Ia., health units, has been appointed Director of Local Public Health Service for the State Department of Health, Lincoln, Neb. Dr. Petty recently completed a course in public health at the University of Minnesota, Minneapolis. He has been succeeded by Dr. JOHN A. COWAN, who has been Acting Director of Public Health for Sioux City and Woodbury County.

ROLLA J. SHALE, M.D., M.S.P.H.,† Director of the Ontonagon-Baraga District Health Department, Ontonagon, Mich., has resigned to accept

* Fellow A.P.H.A.

† Member A.P.H.A.

a position as Director of the Hillsborough County Health Department, Tampa, Fla.

MARY SOULES, M.D., Maternal and Child Hygiene clinician, North Dakota State Department of Health, is pursuing postgraduate work at the Harvard School of Public Health.

HENRY G. STEINMETZ, M.D.,† recently Health Commissioner of Genesee County, Mich., has been appointed Assistant Director in the Bureau of Venereal Diseases of the Michigan State Department of Health, Lansing.

LARS W. SWITZER, M.D.,† of Cassopolis, Mich., Health Officer of Cass County, will serve as Health Officer until the return of LESLIE V. BURKETT, M.D.,† of Flint, in June.

ARTHUR W. THOMAS, M.D., of Columbus, Ohio, Chief of the Division of Child Hygiene, Ohio State Department of Health, has been appointed Chief of the subdivision of child hygiene in the Cleveland Department of Health. Dr. Thomas succeeds RUDOLPH J. OCHSNER, M.D., of Cleveland, who has retired after 30 years' service.

HAROLD B. TURNER, M.D., of Bloomfield, Ind., has been named Health Officer of Greene County.

NEAL B. WILKINSON, Draftsman for the North Dakota Water Conservation Commission, has taken over the position of Draftsman, Sanitary Engineering Division, North Dakota State Department of Health.

Eastern States

WILLIAM STANLEY APPLEGATE,† of Asbury Park, N. J., was recently elected President of the New Jersey Health Officers' Association, succeeding HAROLD W. HAGER, of Ocean City.

DONALD B. ARMSTRONG, M.D.,* Third Vice-president of the Metropolitan Life Insurance Company, New York, N. Y., in charge of Welfare Services for Policyholders, has been appointed a Senior Surgeon in the Reserve Corps of the U. S. Public Health Service.

LOUIS H. COHEN, M.D., of Norwich, Conn., has been appointed Assistant Clinical Professor of Psychiatry and Mental Hygiene at the School of Medicine, Yale University, New Haven.

MORRIS W. COWDEN, M.D., of Gerry, Chautauqua County, N. Y., was recently presented with a testimonial letter by EDWARD S. GODFREY, JR., M.D.,* State Health Commissioner, "in recognition of fifty years of faithful and continuous service as health officer."

GEORGE B. DAVIS, M.D.,† of Milford, Conn., has been appointed as the first full-time Health Officer of Milford.

JOHN H. MUELLER, Ph.D.,† Associate Professor of Bacteriology and Immunology, has been named Professor of Bacteriology and Immunology at the Harvard Medical School, Boston, effective July 1. He will take charge of the Department at the Medical School and at the School of Public Health.

SHERMAN S. PINTO, M.D.,† has been named Supervisor of Industrial Hygiene of the State Department of Health, New Orleans, La. Dr. Pinto is a graduate of the University of Nebraska College of Medicine, and has for some time been associated with the Massachusetts State Division of Occupational Hygiene, Boston, Mass.

ROY M. SEIDEMAN, M.D., Dr.P.H.,† who has been Deputy Commissioner with the Cattaraugus County Department of Health, Olean, N. Y., has been appointed District Medical Officer for Civilian Defense under

* Fellow A.P.H.A.

† Member A.P.H.A.

the New York State Health Preparedness Commission, with offices in Rochester, N. Y.

RACHEL SPINNEY, a graduate in public health from the Massachusetts Institute of Technology and from the School of Public Health at the University of Michigan, has been appointed health education secretary of the Hartford Tuberculosis and Public Health Society, Hartford, Conn., succeeding HELEN MARTIKAINEN, who has resigned to enter the U. S. Public Health Service Staff.

DR. GEORGE S. STEVENSON, Medical Director of the National Committee for Mental Hygiene, has been elected President of the National Health Council, of New York, N. Y., for 1942. He succeeds KENDALL EMERSON, M.D.,* Managing Director of the National Tuberculosis Association, who becomes Vice-President and Chairman of the Executive Committee.

RUTH HARTLEY WEAVER, M.D.,* who has for several years been Registrar of Vital Statistics of Philadelphia, Pa., has been appointed Assistant Director of Health, succeeding the late Dr. Martha Tracy. Dr. Weaver has served as Epidemiologist of the City Department of Health and is Assistant Professor of Epidemiology and Vital Statistics at the Temple University School of Medicine, Philadelphia.

Southern States

ROSCOE P. KANDLE, M.D.,† of Monroe, La., has been appointed Director of the Calcasieu Parish Health Unit.

ELSA ORENT-KEILES, Sc.D.,† who recently has been connected with the department of biochemistry of the School of Hygiene and Public Health of the Johns Hopkins University,

Baltimore, Md., is Assistant Chief of the Food and Nutrition Division of the Bureau of Home Economics, U. S. Department of Agriculture, and in charge of the Nutrition Research Laboratories, Beltsville Research Center, Maryland.

CARL V. REYNOLDS, M.D.,* of Raleigh, N. C., Secretary and State Health Officer of the North Carolina State Board of Health, was elected President of the State and Provincial Health Authorities of North America at their recent meeting in Washington, succeeding FREDERICK W. JACKSON, M.D.,† Deputy Minister of Health, Winnipeg, Man., Canada. Other officers are GREGOIRE F. AMYOT, M.D., D.P.H.,* Provincial Health Officer, Victoria, B. C., Canada, Vice President; and ALBERT J. CHESLEY, M.D.,* Secretary and Executive Officer, Minnesota Department of Health, Minneapolis, Minn., who was reelected Secretary and Treasurer for his 18th term.

Western States

CALVIN L. LONGSTRETH, M.D., has been appointed Health Officer for Bellingham, Wash.

DEATHS

T. R. CROWDER, M.D.,* Director, Department of Sanitation and Surgery, Pullman Company, Chicago, Ill., died April 16.

SIR THOMAS OLIVER, British physician and author of many standard works on diseases afflicting industrial workers, died at Newcastle, England, on May 16, at the age of 89.

DR. ARTHUR PAUL WAKEFIELD, of Belmont, Mass., died February 6.

SHIRLEY W. WYNNE, M.D., New York City Health Commissioner from 1928 through 1933, died April 19, at the age of 59. He returned to private practice in 1934.

* Fellow A.P.H.A.

† Member A.P.H.A.

The Costs of Rural Public Health Services^{*}

W. FRANK WALKER, DR.P.H., F.A.P.H.A.,† W. CARTER
WILLIAMS, M.D., F.A.P.H.A., AND FELIX J.
UNDERWOOD, M.D., F.A.P.H.A.

*Director, Division of Health Studies, The Commonwealth Fund, New York, N. Y.;
Commissioner of Public Health, Nashville, Tenn.; and Executive Officer,
State Board of Health, Jackson, Miss.*

THE purpose of this paper is to give some information on the cost of public health services as rendered in certain rather typical rural areas in two states. It is hoped that this report, based on a study made by the Mississippi and Tennessee State Departments of Health and the Commonwealth Fund, may have some value either in stimulating thought and study along this line or as an aid to administrators in program planning.

Cost data are usually developed in any field for one of two reasons: either to determine the relative monetary efficiency of particular services or methods, or to be used as the basis for the planning of new programs. The expansion of public health services in terms of the number of new units organized has been so rapid in the past few years that little attention has been given to the unit cost

of service and the relative costs of different services in a local public health program. Too frequently the procedure in organizing new units has been to say: here is a county which ought to have a health department; it could probably support one with state help; the population is so much; we can probably find money for a four, five, or six piece unit. Almost without exception staff and budget needs of the area have been underestimated and the wonder is that so many of these newly formed units have survived when the limitations of their budgets are considered.

In any construction work the amount of a particular element that goes into the job is determined after there has been a very careful consideration of the character of the job to be done. The cost of each element is then calculated on the basis of the local supply. If we are building a house we know how much must go into foundation, framing, plastering, finishing, plumbing, heating, lighting, painting, and so forth. But, I hear you say, suppose we want to build

^{*} Read by Dr. Williams before the Health Officers Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

[†] Dr. Walker died September 27, 1941.

a house for only \$5,000 or \$7,000 because that is all the money we have. We must still go back to the unit cost of materials in order to see where we may, by elimination, save the most money and still have a strong basic structure. There are some items that are essential and cannot be eliminated no matter what the cost; other items can be reduced in part without seriously hampering the purpose for which we are building, and still others can be eliminated entirely. This is equally true of public health programs or any other kind of public service endeavor.

The growth of certain phases of the public health program under the impetus of national propaganda, particularly the venereal disease service, has increased the amount of staff time and attention going into this field materially in practically every local health department in the last three years. Where there has been no corresponding increase in staff within the department this increase in attention to syphilis and gonorrhea has been made usually at the expense of other services. If we proceed on the assumption of a fixed budget and personnel as is so frequently the case, we must then ask ourselves whether the increased time spent on these services is in fact worth while. In some instances this increase of time is more apparent than real and because the tuberculosis program or the venereal disease program is being discussed by everyone and is uppermost in the mind, it is assumed that it takes an inordinate proportion of time whether it does or not.

Since the cost of personnel makes up the bulk of public health cost in an area, it is appropriate to begin any study of the cost of services with the distribution of time devoted to the various aspects of the public health program. During 1940, the field staff of 8 county health departments, 6 in Tennessee and 2 in Mississippi, kept time records on all services for the entire

year. Each member of the field staff made a note of the time when each service was begun and when it was finished. This was entered on the daily report form opposite the visit, inspection, or other service. From these notations a special record was made by each professional staff member showing the hours and minutes devoted to the various types of service on a particular day. These time reports contained items which pertained specifically to medical, nursing, dental, and sanitarian services. From these we may get the distribution of time of the professional personnel to the items in the public health program of the area. The professional hours devoted specifically to travel and other related activities have been prorated to the various services. The total cost of medical, nursing, or sanitation services includes not only salary and travel but also the cost of clerical time, general supplies, and overhead. The cost for clerical time, supplies, and overhead was prorated in accordance with the distribution of professional time.

The figure on total cost of medical, nursing, sanitation, and dental professional time per hour thus arrived at is set forth in Table 1 for the several counties. We note that the hourly cost of medical service varied from a low in Lincoln County of \$1.64 to a high in Pike County of \$2.35. In the Tennessee counties the medical costs are based upon full-time personnel. In the 3 small units there is the health officer working alone; in others, there are a health officer and one or more full-time assistants. In the Mississippi counties, the full-time medical personnel is assisted in clinical activities by part-time clinicians employed from the local group. The variation in the per hour costs of nursing service is due almost entirely to the fact that in some counties student nurses made a contribution and their annual rate of compensation is below that of the regular staff. The variation

TABLE 1

Hourly Cost of Health Department Service by Size of Staff and by Type of Personnel, 1940

	Medical	Nursing	Sanitation	Dental
Counties with small staff:				
Blount, Tenn.	\$1.83	\$1.01	\$1.11
Greene, Tenn.	1.89	1.05	1.05

Lauderdale, Miss.	2.07	.92	1.25	\$1.23
Pike, Miss.	2.35	1.12	1.21	.86

in the per hour cost of sanitation personnel from \$.96 to \$1.25 seems to be due primarily to the consuming passion which the single sanitary inspector in Gibson County has for his job. He found approximately 20 per cent more time within the year for his official duties than was reported in other areas.

The cost of a particular service, such as communicable disease or venereal disease, was determined from the hourly cost for professional service and other expenditures. Special supplies, such as drugs for venereal disease clinics, films for tuberculosis, blue ribbons for the school program, maternity supplies for obstetrical nursing care, were charged to the particular service with which they

were associated. Where the laboratory work rendered locally for a particular service could be separated, it was charged to the service with which it was connected. A summation of these costs by services gives the distribution of funds from the local basic public health budget to the various services. The basic budget does not, however, usually include all the public health services which go into the program of the local community.

Though the basic budgets may include local, state, and federal funds, there are other expenditures going into the total cost of public health services. These include contributions by other public agencies in the community, such as civic

* State services include: Laboratory cost, salary of clinicians, x-ray films, vaccines, syphilis drugs, and so forth.

clubs or by voluntary public health agencies, such as the tuberculosis association, services provided by the state for the community, which include diagnostic service for tuberculosis or venereal disease, laboratory service in a number of fields, and also biologicals supplied from state funds. Record forms and literature were supplied in these areas without cost and no attempt has been made to assign money value to these items. Similarly, there is voluntary professional work, particularly from physicians, in connection with school examinations or clinic services that is not included in the basic health department budget.

In Table 2 are shown the total expenditures for public health services in these 8 counties when the cost of services from all sources is included. It will be noted that these states made contributions in service rather than money, to local service, varying from \$1,354 to \$5,025. This is over and above any funds from state or federal sources contributed directly to the basic budget. In those areas in which a training program is carried on, as mentioned above, an appreciable amount of service is rendered by the students.

If we consider the percentage of total expenditures which is represented by state services in the small units, this amounts to from 10 to 13 per cent. In

the units with larger staffs and larger budgets, this is not such a large factor, varying from 3.3 to 6.5 per cent. In Sullivan County, however, a special venereal disease clinician supplied by the state on a part-time basis brings this item up to 12.3 per cent.

In Table 3, the percentage of total expenditures going into each service in each county is shown. It will be noted that the venereal disease program in 5 of the 8 counties takes either first or second place in terms of expenditures. In fact, when the total for the 8 counties is considered, the venereal disease expenditure, varying from \$2,526 to \$14,121, outranks other expenditures, and the cost of school services takes second place. In the two units with obstetrical nursing service, Gibson and Pike, this service is the most costly and venereal disease service second.

If we consider the average expenditures (Table 4) in these 8 counties as relatively typical of large and small units throughout the country, we see that of the \$229,000 spent for public health services in 1940, 22.8 per cent, or over \$52,000, was spent for venereal disease services; 15.8 per cent was spent for school hygiene services, 14.0 per cent for maternity hygiene, 11.9 per cent for infant-preschool, and 11.3 per cent for acute communicable disease control.

If we separate these counties into

those with five piece units and those with a more adequate staff, we see that the ranking of expenditures by services is materially changed. In the smaller units with less adequate staffs, the school program takes the largest expenditure, followed by acute communicable disease control, venereal disease control, general sanitation, and tuberculosis, in that order. In the counties with the larger staffs, the venereal disease program ranks first, followed by maternity hygiene, school, infant-preschool, and acute communicable disease, in that order.

Though the per capita cost of the various services is not the best unit for cost comparisons, it is one which is frequently used and for these 8 counties is set forth in Table 5.

There are some rather interesting modes indicated in this table. For example, an expenditure of 6 to 8 cents per capita for acute communicable disease control is usual. Expenditures of 6 or 7 cents for venereal disease control in small counties are common, but if there is a large urban population and a large clinic service it costs about 20 cents per capita. Counties with active tuberculosis programs spend from 6 to 9 cents for case finding and follow-up. Five piece units have relatively little time for the hygienes other than school hygiene, and spend little money in these brackets. About 10 cents per capita will do a fair job in maternity hygiene, but if a delivery service is included as a part of the program it will cost at least double this amount. It is common

for counties to spend 10 cents per capita for school hygiene services. General sanitation can be financed at about 5 cents per capita and a reasonable food and milk control program at about 2.5 cents per capita.

In Table 6 are shown the total medical cost and the percentage of the expenditure for medical services in the various activities by county. The limitations of the medical staff in the five piece unit and its effect upon the distribution of medical service in some fields will be noted. In 5 of the 8 counties venereal disease service accounts for the largest proportion of medical expenditures. In the other 3 counties it is the acute communicable disease program. Though there is a rather striking uniformity of percentage of medical time devoted to school service by 5 of the 8 counties, the variation in this field is from 8.3 to 23.5 per cent. One would naturally expect a wide variation in the entire time

devoted to the acute communicable disease services, dependent upon the magnitude of the problem. The variation in the school service, however, must depend upon differences in program.

The total nursing cost and the percentage of total expenditures for nursing service allocated to the various activities are shown in Table 7. The expenditure for nursing service in these counties varies from about \$4,500 in the five piece unit to between \$18,000 and \$19,500 in the larger units. In the smaller staffs, the major emphasis is placed on the school program, which accounts for more than 25 per cent of the expenditure. In the 2 counties, Gibson and Pike, which carry on an obstetrical nursing program, the maternity service accounts for the greatest expenditure, amounting to between 40 and 50 per cent in each county.

The demands of the acute communicable diseases upon the small staffs are

indicated by the proportion of total nursing costs going into this field in the smaller counties, which varies in this group from 14 to 23 per cent, while those counties with more adequate staffs spend between 5 and 7 per cent of the total cost of nursing service in this field.

In Table 8 are shown the total expenditures for sanitation services in the counties and the proportion of these expenditures allocated to the various activities. In 7 of these counties the major expenditure is made on general sanitation; however, in Lauderdale County, with a 60 per cent urban population, the bulk of the expenditure is made on food and milk control. This county probably has more nearly completed its job of improving the sanitary condition than any of the others. This is due particularly to the fact that it has had a large staff of sanitarians over a period of years.

It will be recalled that these counties

received from \$1,500 to \$5,000 worth of service from the state departments which does not appear as a part of the basic budget. This represents from 3 to 13 per cent of the total expenditures. The percentage distributed to each service is shown in Table 9. It seems particularly significant that practically this entire expenditure in terms of service from the state department goes into communicable disease control either for the acute diseases, venereal diseases, or tuberculosis.

We may now carry our analysis of unit costs one step further and look at costs of field visits by nursing personnel in the various services. These are set forth in Table 10. The variations here are due to two factors: first, the variation from county to county in the average time devoted to a field visit in each service, and second, the basic cost of one hour of nursing time, which depends upon the salaries paid. It is clear that

TABLE 9

State Expenditure and Percentage by Type of Service and by County, 1940

School	.51	.56	.45	.38	.47	.53	.28	.41

the antepartum visit is the most expensive; that though there is considerable range of costs in some fields, others, like postpartum and school visits, do not vary much from county to county. In calculating these costs, not only the time spent in the actual making of visits but the time spent in travel and the cost of related activities, which it is believed contribute to the success of the visit, are also included.

Sullivan County and less in Lauderdale County than in any other. The high cost in Sullivan is due at least in part to the pneumothorax treatment clinic operated under supervision of the health department. This cost is more than 60 per cent medical in 6 counties. The school examination costs from \$.40 to \$.74. For the average small units it is 59 per cent medical and 41 per cent nursing. For the average large unit, it

TABLE 11

Medical and Nursing Cost per Clinic Visit by Type of Service and by County, 1940

Total	\$.46	\$.54	\$.56	\$.46	\$.74	\$.45	\$.40	\$.67

In Table 11 is shown cost of certain clinic services. In calculating these costs, medical and nursing time have been used but no item has been included for drugs used in the syphilis clinic or x-ray films in the tuberculosis clinic. It will be noted that the total cost of the syphilis clinic visit varies from \$.38 to \$1.17. Tuberculosis clinics cost more in

is 70 per cent medical and 30 per cent nursing.

In Table 12, the cost per inspection of private premises, food handling establishments, and dairy farms is set forth. The inspections of food handling establishments are given for only 3 counties, as the number reported by the others was negligible.

TABLE 12

Cost per Inspection by County and by Type of Service, 1940

	<i>Private Premises</i>	<i>Dairy Farm</i>	<i>Food Establishment</i>
Counties with small staff:			
Blount	\$.62	\$1.78
Greene	.71	1.52
Lincoln	2.09	2.05
Counties with large staff:			
Gibson	.61	1.96
Rutherford	1.75	2.10
Sullivan	.72	1.77	\$1.89
Lauderdale	1.38	3.02	.51
Pike	1.70	2.22	.85

Lauderdale County in 1940 reported 8,617 dental inspections of school children. The cost for this service was 8.9 cents per inspection. Pike County reported 2,496 such inspections at a cost of 21.3 cents per inspection.

We may conclude that program emphasis will and probably should shift and that these distributions of costs will change accordingly. From these analyses, one preparing a budget for a local health department may judge the amount of money needed for certain services. There is no indication that these are the best distributions, but they do represent the cost in representative counties.

From this analysis of time and cost spent in various health department activities in these 8 typical rural counties it seems that:

The basic budget of the health department represents only from 83.9 to 95.3 per cent of the total expenditures.

The cost per hour of medical service varies from \$1.64 to \$2.35; nursing service from \$.92 to \$1.12, and sanitation service from \$.96 to \$1.25.

Field time represents less than half the cost of field and clinic visits.

Time of examination represents less than half the cost of school examination.

In more than half the counties, syphilis clinic service ranks either first or second in expenditures.

In small units, the school service takes from 26 to 28 per cent of the total expenditure for nursing service.

From 23.3 to 67.8 per cent of the money spent for state service is chargeable to the syphilis control program.

The antepartum visit is the most expensive and ranges from \$.97 to \$1.88.

The cost of a syphilis clinic visit ranges from \$.38 to \$1.17; a tuberculosis clinic visit from \$1.05 to \$5.42, and a school examination from \$.40 to \$.74.

NOTE: Details of both time and cost figures are available at the Commonwealth Fund, 41 E. 57 St., New York, N. Y., and will be sent to anyone who desires additional information.

Diphtheria Immunization with Fluid Toxoid and Alum-Precipitated Toxoid*

VLADIMIR K. VOLK, M.D., D.P.H., F.A.P.H.A., AND
WILLIAM EDWARD BUNNEY, PH.D., F.A.P.H.A.

County Health Commissioner, Saginaw, Mich.; and the Former Associate Director, Bureau of Laboratories, State Department of Health, Lansing, Mich.

THE purpose of this study was to investigate the height and duration of the antitoxin response following injection with fluid or alum-precipitated toxoid. When the study began in 1936, immunization against diphtheria was attempted largely by one injection of alum-precipitated toxoid, or two or three injections of fluid toxoid. It was felt to be highly desirable to determine which of these was the method of choice. The most conclusive study would have been a comparison of the resistance to actual exposure to diphtheria following the different immunizing procedures. Since the low incidence of diphtheria made this impossible, it was decided that the next most valuable study would be a comparison of the antitoxin response and the durability of that response.

METHODS

The study has been carried out on 2,487 free-living children from rural schools and communities in Saginaw County, Mich., a county of about 1,110 square miles.

* This study was carried out under grants from the American Public Health Association, provided by the W. K. Kellogg Foundation, and from the U. S. Public Health Service, in cooperation with the Saginaw County Health Department and the Michigan State Department of Health.

Read before a Joint Session of the Laboratory and Epidemiology Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

The immunity response has been followed by blood serum titrations alone. No Schick tests were used because the Schick test itself has an antigenic effect, especially on a child with circulating antitoxin in its blood. Eliminating the Schick test made it possible:

1. To observe the comparative antitoxin response to the various immunizing procedures alone.
2. To follow the duration of the response without giving additional secondary stimulations.
3. To determine the responses to be expected in routine immunization when the Schick test is not used. The decreasing use of the Schick test made this important.

Therefore, before giving any antigenic stimulation, the children were bled. Four or five ml. of blood were taken in vacuum tubes (Keidel or Kimball). Each child was bled again 4 months after the first injection and at 12 months and every 12 months thereafter for the duration of the study.

The blood was titrated essentially by the method of Fraser.¹ The clotted blood was centrifuged at approximately 1,200 r.p.m. for 1 hour, the serum drawn off aseptically, and stored at 2-10° C. The serum of children not previously immunized was first tested to determine if it contained more or less than 0.001 unit of antitoxin per ml. by comparing the reactions in the skin of a rabbit on the intradermal injections of the following mixtures:

Serum Control	0.2 ml. serum + 0.2 ml. saline
Test of Serum for 0.001 Unit	0.2 ml. serum + 0.2 ml. toxin dilution
Standard Control	1.0 ml. N.I.H. antitoxin + 1.0 ml. toxin dilution

The antitoxin in the standard control was the standard diphtheria antitoxin of the National Institute of Health. This was diluted 1:10 with 66 per cent neutral glycerine, in which dilution it keeps indefinitely in the cold. It was then made up to 1:6,000 with saline just before use. At this dilution 1 ml. contained 0.001 unit. The same toxin (No. 358) was used throughout the study and was diluted 1:6,700–1:7,200, varying a little with each new bottle. The optimum toxin dilution was determined by mixing several dilutions of the toxin with each of four dilutions of the National Institute of Health standard antitoxin, namely, 0.001 unit per ml., 0.002 unit per ml., 0.004 unit per ml., and 0.01 unit per ml. That dilution of toxin was chosen which showed the greatest difference in size between the reactions—usually that dilution which gave a + reaction on injection of the 0.001 unit mixture, a \pm reaction to the 0.002 unit, and a negative reaction to the 0.004 and 0.01 unit mixtures. The toxin dilution was always added to the serum, the tubes were shaken, and allowed to stand $\frac{1}{2}$ hour at room temperature. The syringes were filled while waiting, and the intradermal injections of 0.1 ml. of the mixtures made within a second $\frac{1}{2}$ hour period. Clipped white rabbits were used, weighing from 5 to 8½ pounds. Forty-eight injections were placed on each rabbit, including six control injections, three at the front and three at the back. Readings were made on the 3rd and 4th day after injection by comparing the size of the reactions with those of the control injections. The reactions on the front half of the rabbits were compared with

the controls on the front half, and those on the rear half with the rear controls.

If the serum proved to contain more than 0.001 unit it was retitrated, using the following dilutions:

0.01 Unit	0.1 ml. serum + 0.9 ml. saline A
0.1 Unit	0.2 ml. A + 1.8 ml. saline B
1.0 Unit	0.2 ml. B + 1.8 ml. saline

After this titration determined the range in which the titer fell, the serum was again tested. The units tested for in the study were:

0.002	0.02	2.0	16.0
0.004	0.04	4.0	32.0
0.01	0.1	8.0	

The toxin was diluted for all mixtures in Fraser's buffer diluent which has the following formula:

Sorensen's borate—boric acid buffer $\left\{ \begin{array}{l} 12.404 \text{ gm. H}_2\text{BO}_3 \\ 100 \text{ ml. N NaOH} \\ \text{Water to 1 liter} \end{array} \right.$

To one liter add 818.1 ml. 0.1 N HCl to pH 7.9

$\left. \begin{array}{l} 1,070 \text{ ml. buffer pH 7.9} \\ 36.4 \text{ gm. NaCl} \\ 2,210 \text{ ml. H}_2\text{O} \end{array} \right\} \begin{array}{l} \text{Autoclave 1 hour} \\ \text{at } 120^\circ \text{ C.} \end{array}$

0.85 gm. gelatin $\left. \begin{array}{l} \text{Autoclave 1 hour} \\ \text{at } 120^\circ \text{ C.} \end{array} \right.$

Add gelatin and sterile H₂O to make 4,280 ml. after autoclaving.

The following procedures were used in immunization of children:

1. 1 injection of fluid toxoid
2. 2 injections of fluid toxoid (3 weeks apart)
3. 3 injections of fluid toxoid (3 weeks apart)
4. 1 injection of alum-precipitated toxoid
5. 2 injections of alum-precipitated toxoid (3 weeks apart)

The toxoid used was obtained from a commercial firm by Dr. W. T. Harrison of the National Institute of Health so that it would be representative of toxoid generally available. The alum-precipitated toxoid was prepared from the fluid toxoid used in the study. This was felt to be important because of the possibility that two different preparations of toxoid might vary in some in-

trinsic antigenic efficacy for which we have no method of determination. The National Institute of Health tests showed the fluid toxoid to contain 20 L_r per ml. and the alum-precipitated toxoid to stimulate production of an average of 2-4 units of antitoxin in guinea pigs in the National Institute of Health control test for alum-precipitated toxoid. On the re-resolution of the alum-precipitated toxoid it was likewise found to contain 20 L_r per ml. These tests were repeated and verified by the Michigan Department of Health.

A diphtheria carrier survey was carried out in the schools during the study. Throat cultures were taken at intervals from all the school children, irrespective of whether they had received immunizing injections. The throat cultures were examined by the Bureau of Laboratories of the Michigan Department of Health according to the following procedure:

Inoculate a tellurite plate and a Loeffler's plant with the specimen submitted. Incubate at 37° C. for 18-24 hours. Prepare smears from the Loeffler's slant and stain with Loeffler's methylene blue. If diphtheria-like organisms are found, re-incubate the tellurite plate for another 24 hours. Subculture typical colonies to Loeffler's medium and incubate 24 hours at 37° C. Wash off the growth with 2.0 ml. of tryptose broth. Inoculate 1 ml. subcutaneously into the abdominal wall of a guinea pig weighing 250-300 gm., and 1 ml. into a control pig of equal weight which has been previously injected intraperi-

toneally with 500 units of diphtheria antitoxin.

Autopsy pigs at death or at the end of 72 hours. Consider any cultures as toxigenic if the unprotected guinea pig exhibits edema, necrosis at site of inoculation, and hemorrhagic suprarenals, and the protected control guinea pig is normal at the end of the test period. Consider any culture as non-toxic if both pigs are normal at autopsy.

The carrier survey was felt to be essential to the evaluation of the antitoxic response obtained by the various immunizing procedures because one might expect a much higher antitoxin response in a locality with a high carrier rate of virulent diphtheria organisms and a lower response in a locality where exposure to virulent diphtheria organisms is a rarity.²

RESULTS

There are several reasons why the results of this study may be considered indicative of a safe minimum response to be expected from each of the immunizing procedures studied. They are:

1. The children were free-living children from 150 rural schools and their vicinities. A higher antigenic response might be expected from urban children or institutional children.
2. The children were living in a low diphtheria environment as shown by the results of the carrier survey (Table 1) and the incidence of diphtheria (Table 2). A higher response would be expected in the presence of a higher carrier or diphtheria rate.
3. The children were living in a northern state. Children in a southern state might be expected to give a greater antigenic response.³

The fact that 65.9 per cent of the children were 6 to 10 years of age, and 22.3 per cent were in the preschool age group (Table 3) makes the results of the study directly applicable to routine immunization against diphtheria, since these are the age groups usually concerned.

For part of the study, alternate children in a group were given two different immunizing procedures in order to have

a strictly controlled comparison. These were called "Controlled Groups." For the rest of the study, different immunizing procedures were used in alternate schools or communities. These are listed as "Uncontrolled Groups" (Table 4).

It is evident that the results are comparable between the "Controlled" and the "Uncontrolled" groups when the responses of those children having less than 0.001 unit of antitoxin at the time

of injection are compared. This suggests that, in studies on free-living children with no history of previous diphtheria immunization, it may not be necessary to have strictly controlled groups using alternate children if the children having less than 0.001 unit of antitoxin are used and if the diphtheria environments are similar. Since the results with the two groups are similar, they are combined in the rest of the paper to simplify presentation.

The antitoxic response of all children having less than 0.001 unit of antitoxin per ml. of circulating serum at the time of the first immunizing injection is given in Table 5. The response is analyzed at three different antitoxin levels; that is, in terms of the number and percentage of children developing 0.001 unit or more, 0.01 unit or more, or 0.1 unit or more of antitoxin per ml. of circulating serum.

The results in Table 5 indicate that:

1. Under the conditions of this study, two injections of alum-precipitated toxoid or three injections of fluid toxoid at 3 week intervals cause the highest and consequently the most lasting antitoxic response.

2. One injection of alum-precipitated toxoid is superior to 2 injections of fluid toxoid.

3. The immunizing procedure which raises the most children from no detectable anti-

toxin to a detectable level also raises the most children to higher antitoxin levels.

4. Some antitoxin response may be under way within 10 days of an injection of either alum-precipitated or fluid toxoid. This is in accord with the observations of Jensen.⁴

Table 5 reemphasizes the increased antigenic efficiency conferred by the alum-precipitation of toxoid, since the average antitoxin response to a single injection of alum-precipitated toxoid is so much greater than that to either one or two injections of fluid toxoid.

Fitzgerald, et al.,⁵ and Fraser and Halpern⁶ observed an increase in antitoxin following injection of alum-precipitated toxoid comparable to those we are reporting. They observed a much greater response to 3 injections of fluid toxoid than we found. In an attempt to solve this discrepancy, a group of children were injected at 3 week intervals with 0.5, 0.5, and 1.0 ml. of fluid toxoid.* The resulting antitoxin response of children having less than 0.001 unit of antitoxin at the time of injection is shown in Table 6. It is evident that the results with the Fraser toxoid and dosage was comparable to

* Obtained from the Connaught Laboratories through the cooperation of Dr. Fraser.

that obtained in the rest of the study with fluid toxoid in three 1 ml. doses at 3 week intervals. We again did not obtain the high antitoxic response observed by the Canadian workers. We are unable to explain the discrepancy.

The response to the different immunizing procedures of all children having 0.001 unit or more at the time of injection is analyzed in Table 7.

As was to be expected, the response of these children to all immunizing procedures was excellent. There is a suggestion that fluid toxoid is more effective than alum-precipitated toxoid in boosting the antitoxin level where detectable circulating antitoxin already exists. This is only of academic interest, since the immunizing of the non-immune is the important problem. The actuality of this difference could not be gauged unless the results were analyzed on the basis of the amount of antitoxin present at the time of the first injection. Table 8 gives a comparison of the response of those children having 0.001 to 0.004 units of antitoxin at the time of injection.

Although the numbers are of necessity small, Table 8 does carry the same suggestion as Table 7 that fluid toxoid causes a better response than alum-

precipitated toxoid when antitoxin is already present in a detectable amount. It is also interesting to note that even when 0.001 to 0.004 unit of antitoxin is present, three doses of fluid toxoid cause a better response than two, and two doses of alum-precipitated toxoid cause a better response than one.

It can be seen that there is little difference in the response of the different age groups to the immunization procedure used. It is important to know that the response of the preschool group is as good as any other, since this is the most important group to immunize from the standpoint of lowering the diphtheria mortality rate. Blum⁷ likewise found the response of children in the age group 2-4 to be excellent following tetanus antitoxin immunization, but reported that those in the age group 1-2 gave a lower response.

There were no reactions of an allergic nature. From a total of 1,614 injections of alum-precipitated toxoid, two definite abscesses (both sterile) and two reactions suspicious for abscesses were observed. Three of these were in children having less than 0.001 unit of antitoxin and in one having 0.1 unit of antitoxin at the time of the first alum-precipitated injection. We attribute these to technic.

DISCUSSION

This study was concerned solely with the antitoxin response to different immunizing procedures. No attempt is made to prove that any one procedure is the procedure of choice for routine immunization against diphtheria, for two reasons:

1. The ultimate basis for the evaluation of any immunization method is whether or not it protects against diphtheria, and not necessarily whether or not it confers Schick negativity or raises the antitoxin level to any definite point.

2. It is entirely possible that a procedure which results in a lower level of antitoxin than some other may still be the method of choice from the public health standpoint; that is, it might be less expensive, be easier to administer, and confer a high enough percentage of immunity to be the most efficient use of the public health dollar in prevention of diphtheria. It may be a question of choosing between the conferring of the highest possible immunity to the individual on the one hand, and the reduction of diphtheria by conferring a lower

but sufficient level of immunity to the community as a whole on the other.

This study emphasizes the comparatively poor antitoxin response to two injections of fluid toxoid with a 3 week interval and justifies the discontinuance of this procedure for immunization against diphtheria.

This study suggests that the Schick test may be omitted in routine immunization. Certainly there is nothing to be gained by the pre-Schick test in the preschool group—and it is doubtful whether there is any reason to Schick test following two injections of alum-precipitated toxoid or three injections of fluid toxoid until the child enters school—and then, as indicated in the subsequent paper,⁸ a single injection of fluid or alum-precipitated toxoid would be more logical.

SUMMARY

The antitoxin response of children to several diphtheria immunization procedures has been determined. In the decreasing order of the response they induce in children having less than 0.001 unit of antitoxin per ml. of serum at the time of injection, they are, under

the conditions of our study: two doses of alum-precipitated toxoid at 3 week interval, three doses of fluid toxoid at 3 week interval, one dose of alum-precipitated toxoid, two doses of fluid toxoid at 3 week interval, and one dose fluid toxoid.

ACKNOWLEDGMENT—We wish to acknowledge gratefully the technical assistance of Anna Sonderman, R.N., Anita Leavitt, Louise Hagaman Davis, and Nina Smith of the Diphtheria Committee staff for their untiring efforts. We also appreciate the cooperation of Dr. C. C. Young, Director, and Dr. J. P. Tripp, Associate Director of the Bureau of Laboratories, Michigan Department of Health; Dr. L. V. Burkett, Genesee County Health Commissioner; Irene Stiller, and members of the nursing staff of the Saginaw County Department of Health.

Reimmunization Against Diphtheria of Previously Immunized Children*

VLADIMIR K. VOLK, M.D., D.P.H., F.A.P.H.A., AND
WILLIAM EDWARD BUNNEY, Ph.D., F.A.P.H.A.

*County Health Commissioner, Saginaw, Mich.; and Former Associate Director,
Bureau of Laboratories, State Department of Health, Lansing, Mich.*

SEVERAL years ago, the Committee on Administrative Practice of the American Public Health Association suggested the reimmunization of previously immunized children as a means of maintaining a high antitoxin level and so extending immunity to diphtheria for an additional period of years.¹ In the following report, observations are made on the reimmunization of a group of 808 children who had been immunized 1 to 12 years previously.[†]

The objects of the study are:

1. To determine the immunity status of a group of children who previously had received immunizing injections.
2. To determine the immunizing effect of one, two, and three doses of fluid toxoid or one or two doses of alum-precipitated toxoid on previously immunized children.
3. To determine whether previously im-

munized children who at the time of reimmunization have no demonstrable antitoxin would respond better to a single injection than children without demonstrable antitoxin but with no history of previous immunization.

4. To determine whether the reactions from reimmunization with fluid or alum-precipitated toxoid were severe enough to discourage the practice of reimmunization.

Blood antitoxin titration tests instead of Schick tests were used to determine the immunity status and the immunological response.

The details of methods used in immunization and titration are given in a previous paper.²

The entire group consisted of 808 children who had been immunized previously. The years in which they had been immunized and the number of children immunized each year are shown in Table 1.

TABLE 1

Year of Original Immunization

	1922	1929	1930	1931	1932	1933	1934	1935	1936	1937	1938	1939	1940	Unknown

* Read at a Joint Session of the Laboratory and Epidemiology Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, October 17, 1941.

† Throughout the paper, the terms "immunization" and "reimmunization" have been used to mean "the primary giving of antigenic stimulation" and "the secondary stimulation after a lapse of several years" respectively. This was done to simplify the presentation. It is realized that all injected children are not necessarily immunized.

The preparations used in the original immunization were:

Toxin-antitoxin
Concentrated Toxoid
Fluid Toxoid
Toxoid with Alum Added
Alum-precipitated Toxoid

TABLE 2

Antitoxin Titer Levels at the Time of Reimmunization, and the Reimmunizing Agent Used

Antitoxin Titer at Time of Reimmunization	Total Number	Number Reimmunized with	
		Alum-Precipitated Toxoid	Fluid Toxoid
Less than 0.001 unit per ml.	432	265	167
More than 0.001 unit per ml.	376	197	179

TABLE 3

Age Groups at Time of First Immunization

Age (Years)	Under 1	1	2	3	4	5	6	7	8	9	10	11	12	13	14	Unknown
Per cent	3	3	5	8	7	15	26	16	8	5	2	0.9	0.4	..	0.1	2.6

As will be shown later, the results of reimmunization were uniformly good. It follows therefore that the nature of the primary immunization has little effect upon reimmunization response. For this reason the analysis of the reimmunization response has been made without reference to the original immunization preparation or procedure.

A few of the children had received Schick tests soon after their primary immunization treatment. Changes in the immunity of these individuals were noted by comparing the results of the Schick tests made soon after the original immunization with blood titration tests made at the time of reimmunization.

Out of the total of 808 children who had been previously immunized (this total includes both those with and without Schick tests), there were 432 or 53 per cent who had less than 0.001 unit of antitoxin per ml. of serum in their circulating blood at the time of the reimmunization injections, leaving the balance of 376 with 0.001 unit or more.

Table 2 shows the antitoxin levels at the time of reimmunization and the reimmunizing agent given.

Table 3 indicates the age of children at the time of the first immunization. It shows the majority as being 5, 6, and 7 years old.

Eight hundred and eight children were reimmunized as follows:

Fluid	Alum-Precipitated Toxoid
1 Injection: 0.1 ml.	1 Injection: 0.1 ml.
0.5 ml.	0.5 ml.
1.0 ml.	1.0 ml.
2 Injections: 1.0 ml.	2 Injections: 1.0 ml.
at 3 week intervals	at 3 week intervals
3 Injections: 1.0 ml. at 3 week intervals	

Table 4 indicates the age of children at the time of reimmunization. It shows the majority as being from 7 to 11 years old.

A comparison of antitoxin response to different immunization procedures is made in Tables 5-8. Table 5 represents a group of individuals who originally had *less than* 0.001 unit of antitoxin at the time of reimmunization. Table 6 shows a comparison of reimmunization response to a single dose of fluid and a single dose of alum-precipitated toxoid, all children having *less than* 0.001 unit at the time of reimmunization. Table 7 represents a group which had 0.001 unit

TABLE 6

Summary of the Comparative Reimmunization Response 4 Months After a Single Injection of Fluid or Alum-Precipitated Toxoid (All Children Having Less than 0.001 Unit of Antitoxin at Time of Reimmunization)

Immunizing Procedure	Total Number of Children	Antitoxin Titer		
		0.001 Unit or > per ml. per cent	0.01 Unit or > per ml. per cent	0.1 Unit or > per ml. per cent
0.1 ml., 0.5 ml., or 1.0 ml. Fluid Toxoid	122	86	79	48
0.1 ml., 0.5 ml., or 1.0 ml. A. P. Toxoid	228	97	94	64

or more of antitoxin at the time of reimmunization.

As shown in Table 5, observations were made on 432 children having less than 0.001 unit of antitoxin at the time of reimmunization. It can be seen that as little as 0.1 ml. of either fluid or alum-precipitated toxoid produced a significant antigenic response in previously immunized children. The results seem to indicate that either 0.1, 0.5, or 1.0 ml. of fluid toxoid, or else 0.1, 0.5, or 1.0 ml. of alum-precipitated toxoid confers a satisfactory immunity in the majority of previously immunized children. It is also evident that, no matter which immunization procedure was used and no matter what level of antitoxin was achieved, there was always a gradual loss of antitoxin titer with time. In this respect, the results in the reimmunized children parallel the observations made in our study on primary immunization.²

In Table 6, the results from Table 5 showing the response to a single injection of fluid or alum-precipitated toxoid are combined to give a direct comparison between the two antigens. It can be seen that the response to a single injection of alum-precipitated toxoid is slightly better than that to fluid toxoid.

As shown in Table 7, there were 376 children who, at the time of reimmunization, had more than 0.001 unit of antitoxin. This group, as was to be expected, achieved a higher average level of antitoxin than the group of children with less than 0.001 unit of antitoxin. Here again the level of anti-

toxin achieved 4 months after reimmunization gradually fell with time.

Table 8 shows the comparison between a previously immunized and a non-immunized group of children after receiving 1 ml. of fluid toxoid or alum-precipitated toxoid. Both groups had less than 0.001 unit of antitoxin at the time of injection.

It is evident from the study of Table 8 that, although neither group has as much as 0.001 unit of antitoxin per ml. of circulating blood, the previously immunized group was much more responsive to a specific antigenic stimulus. This is in accord with the observations of Dudley, May, and O'Flynn¹ who found that, in subjects known at some time to have been Schick negative, when clinical infection developed, it was followed by a rapid and high increase in antitoxin—a response absent in those not known ever to have acquired Schick immunity.

Table 9 summarizes the response of all children reimmunized with a single injection of fluid or alum-precipitated toxoid. It is evident that, on reimmunization of a group of which 53 per cent had less than 0.001 unit of antitoxin, there is a high degree of response following injection of fluid or alum-precipitated toxoid. The injection of alum toxoid resulted in a slightly higher percentage of response than did fluid toxoid. The results also suggest the advisability of giving children entering school a single injection of fluid or alum-precipitated toxoid without first performing a Schick test.

TABLE 9

Comparison of Antitoxic Response 4 Months After a Single Reimmunizing Injection of Either Fluid or Alum-Precipitated Toxoid (Including All Children Regardless of Antitoxin Titer at Time of Reimmunization)

Immunizing Procedure	Total No. of Children	Antitoxin Titer		
		0.001 Unit or > per ml. Per cent	0.01 Unit or > per ml. Per cent	0.1 Unit or > per ml. Per cent
0.1 ml., 0.5 ml., or 1.0 ml. Fluid Toxoid	239	92	90	70
0.1 ml., 0.5 ml., or 1.0 ml. A.P. Toxoid	404	98	96	78

Table 10 compares the antitoxin response to reimmunization of children who received their primary immunization more than 4 years previously with those who were injected within 4 years. The results do not suggest any loss or gain in response within the time limits studied, regardless of whether or not the children had detectable antitoxin immunity remaining. The results with

those reimmunized within 4 years also confirms the feasibility of the reimmunization at school age of children originally injected in the first or second year of life.

Table 11 emphasizes the quickness of the response of children previously immunized. The comparative slowness in response of children not previously immunized is apparent.

TABLE 10

Comparison of Antitoxic Response Between Children Reimmunized within 4 Years and Children Reimmunized More Than 4 Years After Primary Immunization, All Children Receiving a Single Injection of 0.5 ml. or 1.0 ml. of Alum-Precipitated Toxoid for Reimmunization

	1 Inj. A.P. Toxoid	0.001 or more	11	0	100	100	100

TABLE 12

Comparison of Reactions Following Reimmunization with 0.1 ml. or 0.5 ml. of Fluid or Alum-Precipitated Toxoid

Injection	Total Number in Group	Reactions			
		Mild Per cent	Moderate Per cent	Severe Per cent	General Per cent
0.1 ml. Fl. Toxoid	22	36	0	0	0
0.1 ml. A.P. Toxoid	57	58	2	0	..
0.5 ml. Fl. Toxoid	234	26	8	1	3
0.5 ml. A.P. Toxoid	240	37	14	7	3

Mild Reaction—Local tenderness detectable on pressure, small area of redness

Moderate Reaction—Local tenderness, slight pain on using arm, large area of redness

Severe Reaction—Arm so painful arm not used

General Reaction—Fever and malaise

It was believed very important to determine whether it is safe to reimmunize children. Fraser² has pointed out as a theoretical objection that the giving of doses of alum-precipitated toxoid at long and irregular intervals might possibly result in anaphylactic reactions. In this connection, it was observed that, in the entire group of 808 children, there were no general allergic reactions. It is important to remember that all possible sequences of fluid and alum-precipitated toxoid for primary immunizations and reimmunizations were used.

Table 12 shows that alum-precipitated toxoid produces a higher percentage of local reactions than fluid toxoid. However, as can be seen from this table, general reactions were infrequent following the use of either preparation.

SUMMARY

This study was undertaken to determine the reimmunization response of a group of children who had been immunized previously. It is apparent from observations made on 808 children, some of whom were followed for a period of 5 years after reimmunization:

1. That diphtheria antitoxin immunity, regardless of the immunizing procedure, is not permanent, and that, as time goes on, the antitoxin content of the blood is reduced. It is apparent that progressive reduction of antitoxin content, though slow, is very definite. This has been pointed out by other workers.^{3, 4}

2. That reimmunization with fluid toxoid

or alum-precipitated toxoid is highly effective, and one small dose produces a response in a satisfactory proportion of children.

3. That no general allergic reactions were observed in the entire group, and the percentage of local reactions was not severe enough to discourage reimmunization.

4. That the previously immunized children who had lost all demonstrable antitoxin responded much better to a single injection than children not previously immunized and without demonstrable antitoxin.

5. That reimmunization of children 5 or 6 years after immunization in infancy would maintain the blood antitoxin at a good average level.

6. That alum-precipitated toxoid is somewhat superior to fluid toxoid as a reimmunizing agent, although its comparative effectiveness as an agent for primary immunization is much more striking.

Therefore, the procedure recommended by the Committee on Administrative Practice of the American Public Health Association, consisting of immunization in early childhood and reimmunization upon entering school, is practical. Widespread use of such a procedure should approach complete eradication of diphtheria.

ACKNOWLEDGMENT—We wish gratefully to acknowledge the technical assistance of Miss Anna Sonderman, R.N., Anita Leavitt, Louise Hagaman Davis, and Nina Smith of the Diphtheria Committee staff for their untiring efforts. We also appreciate the coöperation of Dr. C. C. Young, Director, and Dr. J. T. Tripp, Associate Director of the Bureau of Laboratories, Michigan Department of Health; Dr. John D. Monroe, Oakland County Health Commissioner; Dr. Sue H.

Thompson, District Health Officer of West Branch, Mich.; Dr. Charles Benning, District Health Officer of Royal Oak, Mich.; Dr. C. A. Neafie, Health Officer, Pontiac, Mich.; and their staffs, Irene Stiller, Ralph Brown, Ray Illgen, and members of the nursing staff of Saginaw County Health Department have been very helpful to us in carrying on the study.

Properties of Strains of *Corynebacterium diphtheriae* Obtained from Various Parts of the United States*

MARTIN FROBISHER, JR., Sc.D., F.A.P.H.A.

Associate in the Department of Bacteriology of the School of Hygiene and Public Health, The Johns Hopkins University, Baltimore, Md.

IN 1933, the writer and his collaborators, working in the Eastern Health District Laboratory at The Johns Hopkins School of Hygiene and Public Health, in coöperation with the Baltimore City Health Department, undertook a series of investigations of diphtheria carriers, for the purpose of comparing the carrier rate among Baltimore school children at that time with the rate obtained by Doull and Fales and their associates in the same city and, for the most part, in the same schools, in 1921-1924.¹

At the time these studies were being organized, the prevalence of the newly described² *gravis* type of *Corynebacterium diphtheriae*, and its relation to severe and fatal diphtheria, as observed in England and Central Europe, were being discussed in all parts of the world. Little or nothing was known concerning the organism in the United States and, as a result, data were in demand regarding its distribution and epidemiological potentialities in this country. For this reason, in 1936, the Subcommittee on Diphtheria of the American Public Health Association, with the assistance of funds from the W. K. Kellogg Foundation, coöperated with

the Baltimore group, including the Department of Bacteriology of The Johns Hopkins School of Hygiene and Public Health, and the carrier studies originally planned on a local basis were broadened to include surveys of widely scattered portions of the country in several successive seasons. In addition, in 1940, arrangements were made, through the courtesy of the U. S. Public Health Service, to collect cultures of *C. diphtheriae* from persons ill with diphtheria in various cities from coast to coast.

METHODS

A standard method of carrying on the surveys was agreed upon and all collaborating agencies worked to maintain uniformity of field procedures and laboratory technic. Bacteriologists in areas where cultures were isolated from carriers for the purposes of the surveys were given instruction in, and practical experience with, the standard bacteriological method either in the Eastern Health District Laboratory, The Department of Bacteriology, or in their own laboratories, by the writer acting for the committee as the Referee on Bacteriological Procedures.

An accurate and comprehensive study of the cultural properties and virulence of each strain of *Corynebacterium* isolated was made in the Eastern Health

* Read at a Joint Session of the Laboratory and Epidemiology Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

District Laboratories or the Department of Bacteriology of The Johns Hopkins School of Hygiene and Public Health, under rigidly controlled conditions. Details of these conditions and methods have been published elsewhere.² Determinations of virulence, cultural characters and type (*gravis*, *mitis*, etc.), therefore, were the same for all, and conformed as closely as possible to standard procedures and to original descriptions of type. Indeed, an important by-product of these efforts was complete realization of the importance of uniformity in laboratory technic. This was summarized in the statement that "if reports upon the occurrence of *C. diphtheriae* in different parts of the world are to be comparable, the criteria of identification must be equivalent. The designations are not valid unless the strains under consideration have been shown to conform fairly closely to the criteria originally set up by Anderson, *et al.*, as characteristic. . . . Failure of many investigators to describe in detail the full complement of the biochemical characters of their 'gravis,' 'mitis,' and intermediate types, or the methods by which they were determined, or both, renders almost fruitless much of the work in the field."³

RESULTS

Some of the bacteriological results of the carrier and culture studies have already been published,^{4, 5, 13} but these earlier papers, although complete at time of publication, lacked important data which were obtained subsequently and which are briefly summarized in this final communication. The summary of all the work may be given under four heads, as follows:

1. *Culture collection*—Over the period of about 8 years during which these investigations were pursued, and with the collaboration of many persons,

including physicians of the Eastern Health District and staff members and students in the Departments of Bacteriology and Epidemiology of this school, personnel of various state and city health departments, officers of the U. S. Public Health Service, and several bacteriologists in England, there has accumulated in Baltimore a unique collection of over 2,000 strains of corynebacteria, all thoroughly documented as to biological properties and catalogued as to source.

The bacteria are maintained desiccated *in vacuo* and are, in most instances, the same identical individuals which were first isolated in pure culture, being separated from the throat of the patient or carrier only by the following steps:

1. Original cultivation on Loeffler slant directly from nose or throat
2. The above growth streaked on a plate of cystine-tellurite agar
3. Colony fished from the plate to a slant of Pai or Loeffler medium
4. The latter growth, suspended in serum or blood, preserved in vacuum desiccation jars

No culture, so preserved, has so far failed to grow readily on removal from the vacuum jars to blood-dextrose infusion broth. The practical value of this collection of cultures has already been realized by its use as a source of material for several investigations in this laboratory, as a source of type cultures for various investigators in various parts of both hemispheres, and as a source of data referred to in the following paragraphs.

2. *Technological improvements and biological data*—As the work progressed, many technical data of use in the public health laboratory were accumulated and some of the information gained has been valuable in improving methods for the isolation of *C. diphtheriae*, especially from carriers. An example is the formula for the cystine-tellurite agar mentioned above.^{6, 7} The formula was

found to yield a very high percentage (98 or 99 per cent) of isolations of diphtheria bacilli from morphologically positive throat and nose cultures from cases and case-contact carriers, and to detect the diphtheria bacillus and to permit its isolation from many casual, non-case-contact carrier cultures yielding negative whole-culture virulence tests or negative microscopic diagnoses, or both. Its special value in field studies was reported by Frobisher and Van Volkenburgh in 1935.⁸

Pai's egg medium⁹ which had been used to some extent in China as a substitute for Loeffler's medium was thoroughly tested, in a somewhat simplified form, during these studies. The modified "Pai's egg medium, containing no serum, was found to give as reliable results as Loeffler's medium with respect to both morphology and virulence, and to be much simpler to prepare; an important consideration to laboratories so situated that the preparation of complicated medium is impracticable or where the obtaining and storing of serum is a matter of expense or difficulty. Many small laboratories engaged in public health bacteriology encounter such difficulties."⁶ Subsequent statistical studies¹⁰ suggested that the egg medium may sometimes fail to yield expected numbers of *avirulent* strains of *C. diphtheriae* when used for initial cultures from the nose and throat, although there is no difficulty in the isolation of *virulent* strains. This matter deserves further investigation.

A considerable study of the physiological properties of *C. diphtheriae* was also made "with the hope of discovering some . . . property which might be of use in distinguishing between different groups of strains within the species limitations of *C. diphtheriae*. About 150 virulent and avirulent cultures from carriers, cases, and case contacts, including *gravis*, *mitis* and intermediate strains, were subjected to tests for their

power to hydrolyze a variety of substances including carbohydrates, proteins, glucosides, organic acids, etc., as well as for a number of other properties. . . . While our knowledge concerning a variety of biochemical properties of *C. diphtheriae* was increased by the work performed, no correlations which might be of use in establishing groups within the species of *C. diphtheriae* were brought to light."¹¹

3. *Results of carrier surveys, determination of gravis and mitis types, etc.*—The case and carrier studies carried out after 1936, in the country as a whole, yielded data which have proved of interest because, in addition to complementing, in this hemisphere, many surveys made in England, Europe, and other parts of the world, they are the first large-scale data on this subject obtained in the United States. In the interest of brevity, the principal findings may be grouped under three subheadings as follows:

a. *Geographical distribution of certain types of diphtheria bacilli*—Several facts concerning the geographical distribution of diphtheria bacilli were cited in earlier studies, and additional pertinent data collected in the last year are given in this report. Marked differences in types prevalent in certain regions are exemplified by the results of surveys carried on in Alabama and New York State. In 1938–1939, 45 per cent of 104 cultures from Alabama were *gravis* or *gravis-like*, and 28 per cent of these were virulent (Table 1, Line B). Contrasting with this was the situation in Kingston, N. Y., where no virulent cultures and no *gravis* or *gravis-like* strains were found among nearly 1,800 children during the same season. Instead, 23 strains of the *mitis* type were isolated. None was virulent (Table 1, Line F). Data showing similar differences between groups of cultures were obtained in several other areas (e.g., Saginaw, Mich., and Richmond, Va.,

* Not determined for all strains isolated. This figure is therefore an approximation only.

† Exclusive of about 200 cases or contacts.

‡ Includes about 140 case and contact cultures.

Ossining, N. Y., and Kingston, N. Y.), and have already been reported.¹³

Considering the Kingston and Alabama data in the light of recent downward trends in diphtheria carrier and morbidity rates, especially in the North, the question naturally arose as to whether these findings represented a situation in which cultures from northern latitudes were largely of the avirulent and mitis types while those in the South, in general, were more commonly virulent and of the gravis type. It was found on further investigation that this was probably not the case, and that marked differences of this sort can exist in contiguous areas in the South as well as in widely separated zones North or South. For example, a slightly more detailed study of the 1938-1939 Alabama data revealed an interesting difference between two nearby counties. In Randolph County 67 per cent of 43 carrier cultures were mitis or mitis-like in character and 16 per cent were gravis and gravis-like.* The virulent carrier rate was 2.1. In Shelby County, at the same time, of 61 cultures isolated, only 13 per cent were mitis-like, and 72 per cent were gravis or gravis-like.* The virulent carrier rate was 1.0 (Table 1, Lines C and D).

More recent findings show that gravis strains are not necessarily characteristic of Alabama diphtheria carriers, nor mitis strains of the northern children. Shelby County seems to have been an exception. For example, in Alabama, in 1939-1940 in Pike County, 92 per cent of the carrier cultures were mitis-like and none was gravis-like (Table 1, Line E). Investigating a more northerly area, it was found that, of 77 cultures obtained in the Lower East Side of Manhattan, New York City, in the same fall and winter, 10 per cent were gravis-like and 70 per cent were mitis-like (Table 1, Line G).

These facts and similar data obtained in other areas (Cleveland, Ohio, and Baltimore, Md.), all together indicate that: (a) appreciable differences in prevalence of various kinds of diphtheria bacilli may exist concurrently in populations within a few miles of each other; while (b) similarities may exist in culture types found over wide areas; and (c) latitude may have little or nothing to do with the diphtheria flora. More extensive data are obviously needed on the ecology of the corynebacteria.

b. *Differences in prevalence of different types of diphtheria bacilli in successive seasons*—The impression was gained from the results of certain successive surveys that the flora characteristic of a population group in one season may differ considerably in a later season. In some places there was little change from year to year. Unfortunately, however, surveys made in the same area in corresponding seasons of successive years, by the same technic and persons, are exceedingly rare so that no final conclusions may be drawn concerning this matter. While the data available are of great value as bases of comparison for future surveys, they serve best at present to emphasize the desirability of further investigation in the same areas and during comparable seasons.

In Baltimore, for example, the same schools in the Eastern Health District and contiguous zones were examined in several successive years, but not always in corresponding seasons or by the same methods.¹⁰ However, here the flora seemed fairly stable. Thus, in the years 1933-1937, 5.5 per cent of 237 cultures from cases and carriers were gravis or gravis-like. Only one or two gravis-like cultures were found in any one year. Seventy-five per cent were mitis or mitis-like.* No gravis-like strains were found among 17 cultures isolated in 1939, but 88.2 per cent were mitis-like,

* The remaining cultures were indeterminate in character.

the remainder indeterminate (Table 1, Lines K and L).

On the other hand, of 90 cultures obtained from carriers in Alabama in the fall and winter of 1937-1938, 59 (66 per cent) were mitis and mitis-like and 9 (10 per cent) gravis or gravis-like. The proportions differed somewhat in the winter of 1938-1939, while in the spring of 1939-1940, of 49 carrier cultures, 92 per cent were mitis or mitis-like and none was gravis-like.* The former figures are based on Lee, Chilton, and Marshall Counties, the latter on Pike County (Table 1, Lines A, B and E). In Virginia, of 34 cultures obtained from carriers during 1937-1938, none was gravis-like and 32 (94 per cent) were mitis or mitis-like.* In 1938-1939, of 17 cultures isolated during carrier surveys, 11 (65 per cent) were gravis or gravis-like and 2 (12 per cent) were mitis-like* (Table 1, Lines I and J). Here again, the areas studies in successive seasons were different. In the Lower East Side of Manhattan, New York City, during the early months of 1940, 8 (10 per cent) of 77 carrier cultures were of the gravis or gravis-like type, while 54 (70 per cent) were mitis or mitis-like. In the following December, 33 strains were isolated from 498 children, and all of them were mitis or mitis-like (Table 1, Lines G and H).

Differences in the ratio of avirulent to virulent strains or in the virulent carrier rate, or both, were observed in the data collected from year to year in some sections, but not in others. But here again, most of the differences reported are representative only of large general areas, and entire fall-winter-spring survey periods, because not exactly the same populations were examined in each season, and the surveys were not always carried on during exactly the same weeks or months of

each year. The season-area data pertinent to these surveys are shown in Table 1. In Alabama, 18 of 90 cultures (20 per cent) isolated in 1937-1938 were virulent, and 29 of 104 cultures (28 per cent) were virulent in 1938-1939. Contrasting with these figures are those for the season 1939-1940, in which only 2 of 49 cultures (4 per cent) were virulent (Table 1, Lines A, B, and C, Columns 8 and 9). The same counties were not examined each season, but all were near Montgomery. The situation was different in Baltimore where, in 1939, 5 virulent cultures (31 per cent) occurred among 17 strains isolated from 1,102 children (Table 1, Line L). In the same areas, in surveys carried on during 1934-1936, 35 virulent cultures (34 per cent) had appeared among 104 isolated from 3,228 children. Similar to this situation was that in the Lower East Side of Manhattan. Here, during early 1940, of 77 cultures taken from 2,360 children, 14 (18 per cent) were virulent and, in the latter part of 1940, 6 (18 per cent) of 33 cultures obtained from 498 children were virulent (Table 1, Lines G and H, Columns 8 and 9).

Three impressions emerge with some degree of clarity from this rather confusing collection of data. First, bacteriological findings in one season are of no value in predicting the bacteriological situation in a subsequent season anywhere. Second, with respect to the seasons and areas investigated, the ratio of virulent to avirulent strains in the various population groups studied is generally static or downward.† Third, with one or two exceptions, the mitis-like types of *C. diphtheriae* seem to be generally in the majority and may be increasing in prevalence.

c. *The gravis type of C. diphtheriae in persons with clinical diphtheria, their immediate contacts, and casual carriers*

* The remaining cultures were indeterminate in character.

† This does not necessarily apply to carrier rates, although it does in some areas.

in the United States—One of the major objects of this study was to obtain accurate information concerning the frequency of occurrence of the gravis and other types of *C. diphtheriae* in persons with clinical diphtheria and their immediate contacts, as well as in healthy casual carriers, in the United States as a whole. With the coöperation of many interested workers, 178 cultures of *C. diphtheriae* were obtained from clinical cases of diphtheria and from their familial or immediate contacts, during the season 1939-1941 from the places shown in Table 2. In this group of cultures, as is shown in the table, the mitis and mitis-like types were about 9 times as common as the gravis and gravis-like types. Two hundred and seventy-four other cultures were collected from carriers and miscellaneous sources during the same period from various

other places in the country. In this group also the mitis and mitis-like types were greatly in the majority (10:1). All were newly isolated by various bacteriologists. In the whole collection of 452 case, carrier, and contact cultures obtained from all areas in 1939-1941, there were about 9.5 times as many mitis and mitis-like as gravis and gravis-like cultures. This is in general agreement with previous experience in Baltimore where the mitis-like strains greatly predominated, and where there was relatively little change in the situation over a period of years. It is also in agreement with recent findings in New York City where Seligmann has found the mitis, undeterminate and avirulent strains to be greatly in the majority.¹⁷

In the country as a whole, therefore, it seems that, except for small, local, and probably temporary concentrations

of the gravis type, such as have occurred in Alabama and Virginia, and in one small, explosive outbreak in Belair, Md., in 1936, the chance of finding a gravis or gravis-like strain of *C. diphtheriae*, as measured by the surveys of 1933-1941, has been at most not more than 1 in 9. The chance of finding a *virulent* gravis or gravis-like strain in carriers has been even smaller than this; probably no more than about 1 in 40 considering the country as a whole since, of about 180 gravis and gravis-like strains isolated since 1933 in *all* surveys, only about 45 (25 per cent) were virulent. Since these figures include gravis-like as well as *true* gravis* strains, the possibility of finding the latter is still less than 1 in 40, and is more likely to be 1 in 100 or more in most areas.

These observations indicate that, during the period of the surveys, in the areas covered by them, the gravis type of *C. diphtheriae* has been of little clinical significance and is not, at the time of writing this report (June, 1941) a constant or pressing problem to health officers or physicians in general in the United States. It must not be forgotten, however, that some strains of *C. diphtheriae* may be "susceptible, at times, of a tremendous exaltation of virulence, aggressiveness or dispersiveness. The enhancement of virulence (for human beings) does not seem to be manifested in the usual animal tests and may not always be accompanied by gravis cultural characters, but it seems to be found frequently in strains possessing these characters. This enhancement of virulence seems to convert them into extraordinarily dangerous parasites not (greatly) hampered by immunity as we

ordinarily measure it (in human beings). Such strains were involved in the Leeds outbreak and form the basis of the original description of the gravis type of diphtheria bacillus. Therefore, *if* gravis strains are most susceptible of sudden great enhancements of virulence, their increasing prevalence in any community may constitute a potential menace."⁵ A possible example of such a development may be seen in the explosive outbreaks reported in Halifax and Portsmouth, Nova Scotia, in 1940-1941. Strains kindly forwarded to the author by Dr. J. H. Mueller and Dr. E. B. Schoenbach of Harvard University have been of the gravis type.

Perhaps the United States typifies the areas "with mild epidemics and low morbidity" referred to by Seligmann: "In countries with widespread epidemics and severe outbreaks the existence of sharply differentiated types of diphtheria bacilli, often clinically in agreement with the nomenclature of the British authors, is readily confirmed. In countries with mild epidemics and low morbidity, difficulties in differentiating types are often encountered and, if types are found, they do not seem to be of any clinical significance. In such areas one observes many avirulent and atypical strains that cannot be classified as belonging to any one of the described types."¹² The latter two sentences would describe the present situation in the United States.

d. *Establishment of base-line data for future comparison*—In closing this portion of our summary, it is realized that objections may justly be raised against any definite or final conclusions of a comparative nature drawn from the present survey results because of lack of uniformity with respect to season and population groups in each area. It cannot be gainsaid, however, that these surveys provide, as indeed they were intended to do, bases for future comparative studies which are exceptionally

* *True* gravis strains are characterized by the usual properties of *C. diphtheriae* and by: fermentation of starch and glycogen; formation of large "scallop" and irregular colonies on chocolate-tellurite agar; formation of pellicle and early alkalinity in broth; failure to produce soluble hemolysin in broth. *Gravis-like* strains may lack one or two of these properties. *Mild* strains are generally negative or opposite in all respects.

useful because of the unusual degree of uniformity of technic, completeness of record, and other important details which have obtained throughout the whole coöperative effort.

One complaint common to nearly all of the reports of the collaborating members of the Subcommittee on Diphtheria published from time to time, and especially in the Supplement to the March (1940) issue of the AMERICAN JOURNAL OF PUBLIC HEALTH,¹³ has been to the effect that: "Unfortunately no data are available from previous studies of this nature for comparison with the present survey results." or "It is not known what the situation has been in previous years so that no idea of trend can be formed at present." These statements will not be necessary in the future and the committee may well feel gratified that this is so.

4. *Studies of avirulent strains*—It is the experience of most investigators that incidental observations made during the activity of a major research project have sometimes proved to be of no little interest in themselves. So, during the present group of surveys, collateral studies, especially of virulence of corynebacteria, have yielded data which seem to have considerable theoretical and practical value *per se*.

Investigations of virulence of different types of *C. diphtheriae* begun in the summer of 1940 led to the discovery that not only virulent but also the so-called avirulent strains of *C. diphtheriae** are highly lethal when injected intracerebrally into mice. This was reported briefly in 1940, and problems arising from it are still under active investigation.¹⁴

A point of interest in this connection, long under discussion by epidemiologists, concerns the possible rôle of these so-

called avirulent strains in the maintenance of at least a part of the natural ("silent") immunity (as judged by the Schick test) found in children under 10 years of age. In some areas as many as 92 per cent of the children are naturally immune. Virulent carrier rates do not always seem adequate to the maintenance of such widely distributed natural immunity. Data have been obtained in preliminary investigations made in this laboratory, and already reported in abstract,¹⁵ indicating that immunization with these organisms may give some protection against virulent strains, but the results are as yet merely suggestive. Detailed information may be published later.

Additional studies of virulence have revealed the fact that 7 to 14 day old chicks (unless protected with antitoxin) are highly susceptible to diphtheria toxin and to virulent cultures, and *not at all* to avirulent strains or diphtheroids, and so may serve as substitutes for guinea pigs and rabbits in routine virulence tests, or in estimations of the potency of toxins, antitoxins, etc., with the advantage that they are readily obtainable at all times from hatcheries or the laboratory incubator at a cost of 8 to 15 cents apiece.¹⁶

SUMMARY

1. A study of strains of *C. diphtheriae* isolated from healthy, casual carriers, persons with clinical diphtheria, and the familial or other immediate contacts of the latter, has been conducted in collaboration with national, state, and local health agencies in the United States. A large collection of pure cultures (about 2,000) representing 17 states from New York to California and Minnesota to Mississippi, has been carefully studied and described and is maintained desiccated *in vacuo* in the material in which originally isolated.

2. Investigations carried on in the laboratory concurrently with the field studies have led to several improvements in methods for isolation of *C. diphtheriae* from the throat, especially of carriers.

3. Carrier surveys have shown that any

* Organisms indistinguishable from ordinary *C. diphtheriae* except that they cannot be shown to be toxigenic by means of rabbit and guinea pig tests.

type of diphtheria bacillus, e.g., gravis or mitis, virulent or avirulent, may predominate and at times may be the only type present in some communities but not in others. It was found that this phenomenon may be extremely localized or very general, and that, under present conditions in the United States, conclusions in regard to type prevalence or rates are not valid beyond the confines of a county or state, and often a town or village.

4. The data suggest that changes may occur from year to year in any given area in the prevalence of gravis, mitis, and other types of diphtheria bacilli, and in the ratio of virulent to avirulent and mitis to gravis strains as well as in the absolute numbers of either. However, further information is needed concerning these problems before generalizations can be made. In the meantime, descriptions of diphtheria carrier rates, types, virulence, etc., should state accurately the time as well as the area covered, in addition to the methods used in obtaining the data.

5. Many of the strains of the gravis type of *C. diphtheriae* encountered in carriers in the United States during these studies are wholly avirulent when tested by the usual methods.

6. In a group of over 175 cultures obtained from clinical cases of diphtheria, and their household contacts, between November, 1939, and March, 1941, in various parts of the United States, there were about 10 times as many mitis and mitis-like strains as gravis and gravis-like. About the same ratio was found among 181 carrier cultures obtained in 1939-1941 from Alabama, Baltimore, New York City, and Utah (11:1). Among 452 cultures obtained from all sources in 1939-1941, 361 were mitis or mitis-like, and 38 were gravis and gravis-like (a ratio of about 9.5:1).^{*} The mitis-like type of *C. diphtheriae*, therefore, is at the time of writing (June, 1941), about 10 times as common as the gravis-like type in the United States. Since only about 1 in 10 of the latter is of the true gravis type, and virulent at the same time, probably not more than about one strain of *C. diphtheriae* in over 100 in the United States is of the virulent and genuinely gravis type except in a certain few, sharply localized areas where outbreaks have occurred.

7. The gravis type of *C. diphtheriae* is not an important health problem in the United States at present, but may become so at any time.

8. The data presented or referred to herein constitute a sound basis for future investiga-

tions on the epidemiology and bacteriology of diphtheria in the United States.

9. Studies of the virulence of organisms of the genus *Corynebacterium* showed that (a) 7 to 14 day old chicks are, in many respects, more desirable subjects for testing the virulence or toxigenicity of diphtheria bacilli, and for measuring the potency of toxin, than are guinea pigs and rabbits, and are an entirely practical substitute for these purposes, within certain limits; (b) although mice are highly resistant to virulent cultures of *C. diphtheriae* and to diphtheria toxin injected intraperitoneally or subcutaneously, they are highly susceptible to these materials injected intracerebrally; (c) not only are they susceptible to virulent cultures and to toxin, but they succumb with almost equal regularity, and exhibit exactly the same highly characteristic symptomatology when similarly injected with cultures of *C. diphtheriae* which are avirulent as determined by the rabbit, guinea pig, and chick tests.

ACKNOWLEDGMENT—It would require much more space than is available to thank individually and adequately all who have contributed to this report. Only through the wholehearted coöperation of the Commissioner of Health of the City of Baltimore, Directors of the Eastern Health District of Baltimore, the members of the Subcommittee on Diphtheria of the A.P.H.A., the National Institute of Health, Directors of the State Bacteriological Laboratories, and the individual bac-

teriologists therein and many other interested scientists both here and abroad has the work been possible. Special acknowledgment is due to Dr. E. I. Parsons, Research Assistant at the Johns Hopkins School of Hygiene and Public Health, who has done much of the laboratory work since November, 1937.

Nearly 100 cultures were sent by Miss Margaret Beattie, of the University of California, while Dr. A. S. Gilliam, of the U. S. Public Health Service, arranged for many of the cultures from cases and contacts.

The author is personally indebted to present and former members of the Departments of Bacteriology and Epidemiology of this School, and especially to Dr. Thomas B. Turner, Dr. Kenneth F. Maxcy, and the late Dr. Wade Hampton Frost, for their advice and encouragement during the years occupied by this work.

Public Health Activities of the American Red Cross

ALBERT McCOWN, M.D., DR.P.H., F.A.P.H.A., AND
AMOS CHRISTIE, M.D.

*Director and Assistant Director, Medical and Health Service,
American National Red Cross, Washington, D. C.*

THE questions we have been asked in the months since our association with the American Red Cross have led us to the conclusion that for an organization that has functioned as long and that has been as prominently in the public view as the American Red Cross, there is a surprising lack of sound knowledge as to what its objectives are and how it operates.

It is, therefore, the purpose of this paper to review, define, and to reemphasize the responsibility and function of the Red Cross as a public health adjunct.

Since its organization the Red Cross has included medical and health services and public health work among its major activities. The very connotation of the words "Red Cross" brings up the idea of services of health and welfare.

Most of us can agree that the protection of the public health is a function of government. Likewise we can agree that voluntary health agencies should continue to exert their efforts toward supplementing and supporting the work of these official agencies. In this understanding of function and relationships the Red Cross makes a significant contribution to the national welfare by its educational and service efforts in the field of public health.

Being semi-official, non-political, and

non-partisan, with an emblem known everywhere, a prestige gained from accomplishment in doing the job and 3,743 local Chapters in the United States, the Red Cross will continue to make these contributions, in peace and in war, to improve the public health and welfare.

The activities of the Red Cross in foreign service, in disaster relief, and in public health nursing are well known. Its instruction courses in First Aid, Water Safety, Accident Prevention, Home Nursing, and Nutrition have furnished leadership which has improved and extended what the official agencies have today. Broadly speaking, all services of the Red Cross have health and welfare significance, but the activities of some are so pertinent to our present defense and war efforts that some detail is indicated.

DISASTER RELIEF

For purposes of definition, a disaster is a situation, usually catastrophic in character, in which numbers of people are suddenly plunged into helplessness and suffering.

The immediate objective behind disaster aid is that of meeting emergency needs, be they medical and surgical—or food, shelter, clothing, and the replacement of household goods and property. The ultimate objective is to assist

the victims of such catastrophies in taking up life where they left off when the disaster struck. The Red Cross does not replace all losses caused by disasters—since some of these losses occur among those who are self sustaining through reserve funds, insurance, or through available community facilities. It does attempt to meet immediate needs and rehabilitate those who, because of the disaster, would be destitute. With this program it supplements, does not duplicate, the public and private resources of the community.

The Disaster Relief Service operates through its national staff and through the facilities of its local Chapters, utilizing their welfare, health, and other services. In this service the Red Cross clearly defines its relationship to existing medical and public health agencies.

The American Red Cross recognizes that the primary responsibility for the care of the sick and injured in disasters rests with the local physicians. Red Cross medical service in Disaster Relief does not substitute for the services of local physicians and dentists, but coop-

When Disaster Strikes*

erates with them by assisting in the organization and direction of the medical and relief work and by providing the facilities which they may lack. Every effort is made to maintain and reestablish as quickly as possible the predisaster relationships between physicians or dentists and their patients. If emergency hospitals are needed in the first few days, these are closed as soon as practicable and the patients returned to their physicians.

We believe that this broad program of relief and welfare is an endeavor representing the Red Cross at its peacetime best. With a background of experience and a national organization used to supplementing local aid when disaster strikes, the Red Cross is in a position to operate and cooperate effectively in disasters caused by disease, flood, tornado, earthquake, and belligerent enemy action.

RELATIONSHIPS WITH OFFICE OF CIVILIAN DEFENSE

Any review of the activities of the Red Cross Disaster Service naturally suggests the functional relationships between the Red Cross and the Office of Civilian Defense. In the agreement between the Chairman of the American Red Cross and the Director of the U. S. Office of Civilian Defense, the Red Cross has agreed to make available all of its facilities in time of emergency caused by enemy action. Recognizing the basic responsibility of government, it is the duty of every Red Cross Chapter and Branch to aid in the most efficient marshalling of the resources of the community. It is further agreed that duplication should be avoided, and that the training courses required in civilian defense and the long established nation-wide facilities of the Red Cross should be utilized to the fullest extent.

Services required in civilian defense activities should be made available by Chapters to local Defense Councils.

Chapters should cooperate to the fullest extent and, during the period of emergency, should operate subject to the authority of the Defense Councils or appropriate governmental officials. Red Cross at all times will maintain administrative and financial control of its immediate operations.

In the comprehensive planning required for emergencies caused by enemy action, it is inevitable that confusion will arise as to function and responsibility. As we have viewed this problem on the national level and have heard reports from local areas, two factors it seems are responsible for this confusion.

1. The unwillingness of some individuals in local Chapters of the Red Cross to realize the need of integration of all services in time of disaster under one responsible authority.

2. The desire of certain Office of Civilian Defense representatives to take over and supervise all functions of all voluntary agencies before and during the emergency.

Much of this confusion, we believe, could be avoided if all local Red Cross Chapters would realize the need of coordination of activity and central control at the time of disaster, and if all Civilian Defense organizers would realize that the Red Cross Chapters have their regular programs to carry on before emergency strikes and are not subject in preemergency periods to the authority of civilian defense.

SERVICES TO THE ARMED FORCES

It is erroneously assumed by some that the Red Cross is primarily responsible for the health of soldiers and sailors and the wounded in time of war. This is not the function of the Red Cross, but is the function of the Medical Departments of the Army and Navy. Without attempting to outline the numerous specialized activities which are involved, the scope of the Red Cross services to the armed forces may be broadly described as follows: The Red Cross conducts social service

and recreation activities for the benefit of members of the armed forces in Army and Navy hospitals wherever they may be. This includes medical and psychiatric social service in the general hospitals of the Army and Navy for the large number of patients who require this specialized assistance. The program on behalf of the hospitalized service men is particularly designed to aid service men during the convalescent period before they are able to return to duty, a period when morale is likely to be lowest. This service also provides for cases arising among service men which may involve communication with, and sometimes aid to, their families for the solution of special difficulties.

FIRST AID

First Aid as taught by the American Red Cross stresses the immediate emergency care given the victims of an accident in the absence of a physician. A good instructor will emphasize the negative aspects—what not to do—as well as the positive. Much confusion as to procedures outlined in the course would be avoided if it were constantly kept in mind that First Aid Instruction is designed primarily for the layman in giving emergency care before the arrival of a physician.

From June, 1910, to December, 1941, the Red Cross First Aid division issued three million certificates for completion of its Standard Course. Since entry of the United States into World War II the Red Cross has issued over five million textbooks. Certificates for the completed course are now averaging over 300,000 each month—or four million a year.

NURSING SERVICE

The Nursing Service of the American Red Cross is charged by act of Congress with the responsibility for maintaining a reserve of nurses adequate at

all times to meet the needs of the armed forces. The Army and Navy expect to supplement their Nurse Corps from this reserve, all members of which have been certified by the American Red Cross as meeting the requirements of the Army and Navy Nurse Corps. This procedure relieves the Army and Navy of the preliminary investigation of all applicants and enables them to concentrate on the problems of assignment. A Red Cross nurse, once she is assigned by the Army or Navy, becomes a member of the Army and Navy Corps and is entitled to all benefits accruing to Army and Navy personnel.

This enrollment of Red Cross nurses becomes vitally important when the United States is at war. During the past twelve months 13,166 nurses were added to the Red Cross First Reserve roster. In addition there are now 60 American Red Cross nurses on duty in England, working as a part of the Red Cross-Harvard communicable disease unit, and a unit of 75 nurses, half of whom are now on duty, to supplement nursing service to the civil population in Hawaii.

In meeting disasters which occur in normal times and not as a result of total war, Red Cross Nursing Service plays an active part. There were only 22 days during the last fiscal year in which no nurse was engaged in disaster nursing, and at present the Red Cross maintains on call throughout the country a small reserve of nurses experienced in disaster nursing.

There are still many sections of the country where the official health agencies have not developed a nursing program. It is in these areas that the Red Cross Chapters are carrying on public health nursing. It is recognized as fundamental that the Red Cross Nursing Service pioneers and supplements—does not supplant—state and local nursing programs.

In the promotion of positive health,

it is recognized that the people themselves should assume some responsibility for maintaining their own health standards by awareness of symptoms which indicate ill health. To meet this need courses in Red Cross Home Nursing are offered. These are taught by professional nurses, and consist of at least 24 hours of practical instruction in how to keep the family well. The objective is to provide simple nursing care in the home to members of the family who do not need continuous hospital and nursing care. Last year 80,000 certificates were granted; this year it is estimated that more than a half million people will complete the course.

In view of the present demand for an adequate supply of nurses, and recognizing that the most important objective is to increase in every way the normal supply of graduate nurses, it yet seems clear that nurses' aides and assistants of several different kinds are needed to care for the sick and to prevent illness in our country in this time of war. It was, therefore, decided in July, 1941, that the Volunteer Special Services of the Red Cross and the Red Cross Nursing Service should collaborate in the development of a nationwide program for the training of Volunteer Nurses' Aides. In 45 states and the District of Columbia. 449 Chapters are carrying on such programs, and the American Red Cross has been designated by the Office of Civilian Defense as the sole training agency for these volunteer nursing aides.

NUTRITION

The Red Cross nutrition program today has a vital double significance in the total war effort of the nation. It helps build civilian power behind military power by providing men and women throughout the country with the knowledge of food needs and food values upon which stamina, working efficiency, and morale depend. It is

primarily a long-range, continuing program of education directed to all income groups.

The Red Cross nutrition program is also an emergency program, training groups of lay volunteers in the preparation and serving of food in large quantities under emergency conditions in readiness for situations that might arise from disasters or enemy action.

JUNIOR RED CROSS

The American Junior Red Cross is a division of the membership of the American National Red Cross. Its 1942 estimated enrollment of 14 million is restricted to school pupils, including children in public, private, and parochial schools.

The purpose of the Junior Red Cross is to promote positive health, to provide opportunities for the participation of youth in worth while service activities, to give practice in responsible citizenship, and to assist in promoting international understanding.

This reserve of youth presents a dynamic potential and design for healthy living.

VOLUNTEER SPECIAL SERVICES

The purpose of Volunteer Special Services is to maintain in every Chapter regular services to the community, such as Production, Canteen, and Motor Corps. This provides a group of volunteer workers trained by year-round activity for prompt and efficient service in emergencies, those peacetime emergencies such as floods, fires, tornadoes, and the greater emergency of war. For example, last spring the Red Cross was requested to produce for the Army a reserve of 40 million surgical dressings and the Production Service is approaching the completion of this very practical task.

MEDICAL AND HEALTH SERVICE

In 1940 and 1941 the following new

projects were undertaken as a part of Red Cross participation in the national emergency program.

Enrollment of Medical Technologists—As of April 30, 1942, 25,196 inquiries had been made by medical technologists, 7,452 applications had been received, and there was a total net enrollment of 3,853. A sensitive index of the increased activity of the Red Cross since the attack on Pearl Harbor is shown by the increase in the number of inquiries from persons desiring to enroll as medical technologists. In contrast to the 1,061 inquiries received from June 30 to November 30, 1941, a period of 5 months, there were 1,357 inquiries received during the month of December alone.

The Doctors for Britain Project—In cooperation with the Office of Insular and Foreign Operations, the Medical and Health Service has assisted in answering the appeal of the British Red Cross to the American Red Cross to enroll American doctors to meet the shortage of doctors in British military and civilian hospitals. The doctors recruited are serving on the staffs of the Emergency Medical Service and in the Royal Army Medical Corps.

The Project for the Correction of Remediable Defects of Registrants Rejected for Military Service—The project for the correction of remediable defects of registrants rejected for military service was undertaken at the request of the Medical Advisory Committee of National Selective Service, and was a cooperative project of Selective Service, the District of Columbia Medical Society, the District of Columbia Dental Society, the Health Security Administration of Washington, D. C., and the American Red Cross. Objectives of the study were:

1. To determine the number of deferred registrants with remediable defects
2. To determine the number willing to have such defects corrected

3. To estimate the cost of remedying such defects

The findings of this study are now being used by Selective Service in estimating costs in state-wide rehabilitation projects.

The Blood Donor Service—In January, 1941, the American Red Cross and the National Research Council were requested by the Surgeons General of the Army and Navy to organize a cooperative project for collecting human blood to be processed into dried plasma for the medical departments of the Army and Navy.

The American Red Cross with the help of certain Chapters in the larger cities is responsible for enrolling the volunteer donors, safeguarding their interests, and delivering the blood collected to licensed biological companies who have contracted to process plasma. The Medical Division of the Research Council is responsible for instituting and directing all the technical phases of the work, particularly as it relates to the technic of taking blood from the donor and selecting or approving the collecting units to be used.

The original request presented by the Surgeons General called for the collection of a minimum of 10,000 pints of blood plasma to be dried and to be available for treatment to the armed forces. In May, 1941, the amount requested was increased to 215,000 units. This amount was increased materially following the attack on Pearl Harbor and the declaration of war. All told, a total of 1,280,000 units have been requested as of April 4, 1942.

To meet these requests, the Red Cross has opened Blood Donor Centers as rapidly as laboratory facilities to process the blood have become available. On December 7, 1941, 9 Centers were in operation. As of April 4, 1942, 18 Centers are in operation. 217,731 pints of blood have been collected, and total donations are being obtained at

the rate of more than 17,000 a week.

Blood collected by the 18 Red Cross Centers is shipped daily in refrigerated containers to the laboratories which have agreed to process it into dried plasma for the Army and Navy. Because of the many technical and financial factors involved, including the fact that the blood must reach the laboratory within 24 hours after it is drawn, the location of Centers has been restricted to areas near cities in which the processing laboratories are located.

Volunteers have responded willingly to the Red Cross call, and numerous cases have been reported in which emergency transfusions of plasma have saved or helped to save the lives of wounded American soldiers and sailors. Arrangements have also been made whereby emergency supplies of dried plasma will be available through the Red Cross in event of civilian disaster in this country.

Red Cross Blood Donor Centers are located in New York, Philadelphia, Baltimore, Buffalo, Rochester (N. Y.), Indianapolis, Detroit, Pittsburgh, St. Louis, Boston, Cleveland, San Francisco, Milwaukee, Los Angeles, Chicago, Cincinnati, Brooklyn, and Washington, D. C.

THE FUTURE

Today the activities of the American Red Cross are focused on meeting the demands of adequate defense and the needs of our fighting forces. But when the war is over and victory is secured, needs of reconstruction in this country and all over the world will tax the resources not only of the Red Cross but of all other agencies of good will. As the appeal came and was met after the last war, so it will be met again. In providing these services the Red Cross will not have to be called in—it will be there.

A New Technic of Health Education for Use in Baby Stations

JULIUS LEVY, M.D., F.A.P.H.A., MAYHEW DERRYBERRY,
PH.D., F.A.P.H.A., AND IVAN MENSCH

*Director, Division of Child Hygiene, Department of Health, Newark, N. J.;
Senior Health Education Analyst; and Junior Social Science Analyst,
U. S. Public Health Service, Washington, D. C.*

INTEREST in the use of tests as a technic for motivating the general public to acquire information has recently been stimulated by the use of quiz corners as teaching devices in health education and other fields.* In Newark, N. J., the Baby-Keep-Well Stations have adapted with considerable success the popular quiz session to an educational purpose, through the employment of "True or False" contest methods with groups of mothers who attend conferences.

As originally planned, using true-false statements as an educational device had as its primary objective instructing mothers in proper procedures for infant care. When the plan was put into operation, however, it developed that it was equally valuable for other purposes. It pointed out to the physicians those facts about baby care that were relatively or completely unknown to many of the mothers, and it also uncovered a number of wrong ideas which the mothers had. By concentrating on facts that were unknown and on the correction of wrong impressions, the physicians were able to make their instruction much more profitable. Furthermore, if he had previously

taught some point now being tested, a physician could judge how effective his instruction had been.

The test questions constructed for initial trial dealt with the following phases of maternal and child hygiene:

- Feeding
 - Artificial or bottle feeding
 - Breast feeding
 - Cod liver oil
 - Orange juice
- Development
 - Habit training
 - Sleep
 - Teething
- Common infant disorders
 - Constipation
 - Cradle cap
 - Crying
 - Diarrhea
 - Vomiting
- Care of diaper and skin
- Clothing
- Fresh air

The questions were prepared by the physicians and were, in general, based on actual experiences at baby stations.† Many of them were intended to present mistaken or commonly held ideas such as: "Crying injures a baby's lungs." "Teething causes colds." "Belly bands keep the back straight."

After the first contests in the fall of 1940, succeeding ones have been con-

* See, for example, "Using Tests as a Medium for Health Education," Mayhew Derryberry and Arthur Weissman, *Public Health Reports*, vol. 55, 1940, pp. 485-489, and "The Quiz Corner as a New Informational Technique," Bureau of Agricultural Economics, United States Department of Agriculture, July, 1941.

† The use of the quiz session in Baby-Keep-Well Stations and the original set of questions were suggested by Dr. Ralph N. Shapiro, a member of Dr. Levy's staff.

ducted at intervals ranging from 1 to 3 months, with from 5 to 15 participants at each. The physicians at the stations have, in each instance, announced the date of a contest several weeks in advance and reminded the mothers in the interval. In addition to the physician's reminder, the nurses during home visits have encouraged mothers to attend.

Although in general the quiz sessions have been conducted as contests, a few physicians have preferred to omit the competitive feature and have, instead, a question-and-answer period. In each instance the physician introduced the session with a brief informal talk in which he explained the method that would be used, and usually compared it with the radio quiz programs with which most people are familiar.

In conducting the contests, two distinct methods have been used. When the first method is followed, each mother in turn is asked a question. About 25 questions are used, so that each participant has an opportunity to answer once or twice, to give reasons for her own answers, and to comment upon those given by others. According to the second method, the group is divided into competing teams. The division may be arbitrary, based on seating arrangement, for example, or on some characteristic such as the number of children a mother has. In the team arrangement the usual method of scoring has been to give one point for each correct answer and an additional one or two points' credit for a correct explanation or reason for the answer. If the individual who gives the correct answer (true or false) cannot also furnish a correct explanation, the other side is given a chance to do so. The physician who conducts the contest also briefly summarizes the information after each question has been discussed.

In the time allotted to a contest with its attendant discussion (usually less than an hour) the physicians find that

they can use 18 to 25 questions, selecting those pertinent to the problems most commonly found in their particular stations. Since there are available 160 questions* from which to select, the physician has considerable latitude with respect to the topics he may wish to have discussed. By conducting the contest before the child health conference, it has been found that in general attendance has been improved.

Since the true-false contest was a new technic in health education, there was need for some evaluation of its effectiveness, when used by several physicians, before its real value could be determined. In order to find out more exactly how the method operated, stenographic transcripts of contests conducted by 7 physicians, each in a different health station, were taken between November, 1940, and April, 1941.

Five of the physicians used about 25 questions each, but the other 2 used 146 and 62, respectively. In the latter two contests, the percentage of questions about which there was no comment, discussion or explanation was 60 in the first case, and 90 in the other. The doctor sometimes said, "Yes, that's right," or "No, that's wrong," but gave no further interpretation. It would appear that at least those two contests achieved only a very limited amount of teaching, since there is nothing in the record to indicate that the physicians even made certain that correct answers were not the result of guess work.

Contrasted with the type of contest which is little more than a recital of questions are the other 5 of the 7 analyzed. There was discussion and explanation in over 90 per cent of all instances and in no case was a question passed by without some comment. In

* Mimeographed copies of the questions are available for limited distribution on request directed to the Health Department of the City of Newark, N. J., or to the Division of Public Health Methods of the National Institute of Health at Bethesda, Md.

two of the contests there was not a single question to which the answer was not discussed.

In the type of situation when there is secured not merely information in the form of discrete items of fact, but an understanding of related facts and an explanation of reasons, it is surely fair to say that real teaching has been achieved. The physician, therefore, has opportunity to find out what the participants know or do not know and also to present new or unfamiliar information, correct wrong impressions, and make sure that reasons are properly related to practice. That can only be done, however, if the physician observes certain cautions in using the contest technic in his child health station. As one observer remarked after seeing a true-false contest: "The success of the contest depends almost entirely upon the person who runs it, and how he does it." The manner in which the physician conducts the quiz is most important to the effectiveness of this method of teaching mothers. This implies active participation by the physician, not a mere recital of a series of items.

The first two contests discussed above illustrate test situations in which the educational value was reduced and definitely limited by the use of large numbers of questions. Mere recital of questions consumed a major part of available time and allowed little or no explanation. The "all right," "yes," "that is correct" type of comment by the physician serves as praise for the one participant to whom it is directed and is a source of satisfaction only to her. However, others present can derive no educational benefit from non-informative comment; hence a valuable opportunity for teaching is lost when there is not additional explanation of answers. Such discussions need not be long or very detailed. The following transcripts emphasize the importance of the physician's position as educator:

1. Always shake a lot of powder on the buttocks when the baby wets. True or false?

Doctor A

Mother: False.

Dr.: Why is that wrong?

M.: It's not necessary. It sticks and cakes. You can oil the baby, use olive oil. For one thing, I have heard you can give the baby pneumonia from the dust.

Dr.: This mother has thought about this. It will cake around the creases. Dust the powder on a puff and put it on. But the baby cannot get pneumonia from putting powder on the buttocks.

Doctor B

Mother: False.

Dr.: Correct.

2. Never use table sugar in the formula—there is not enough nutrition in it. True or false?

Doctor A

M.: False.

Dr.: Why?

M.: Because I never heard of any other kind of sugar to use for a baby.

Dr.: Table sugar is just as good for a small baby as any other sugar. Only in special cases do we use other sugars.

Doctor B

M.: That is false.

Dr.: You are right.

3. Teething causes colds in babies. True or false?

Doctor A

M.: False.

Dr.: Why?

M.: Teething does not cause any kind of illness. Baby may not have been dressed properly. It may have been in a draft.

Dr.: That is what we are trying to bring out. Teething only causes teeth.

Doctor B

M.: False.

Dr.: That's right.

In any evaluation of the quiz technic in health education, it is necessary to consider, in addition to its effectiveness in terms of learning, the attitude that it

produces in participants. The following transcripts are indicative:

Physician: I should like to ask you mothers what you think of these contests. Do you like this method?

Participant: Very much.

Physician: Do you think it makes much difference if you know *why* things are done?

Participant: I think if you know *why* you do these things, you are more apt to *do* them, and do them *right*.

Physician: Do you like this session, mothers?

Participant: Yes. Very much.

Physician: All of you?

Participants: Yes. You learn something. Have questions on older children next time.

The physicians conducting the contests have also expressed their opinions of the technic in such ways as:

Dr. A: I think it's the best means of getting discussion. It's the best way the Baby Station can get all the mothers to take part.

Dr. B: The contests are nice, but I think the information you want to get across is better delivered by the 5 or 10 minute talks we give all the mothers before each conference. The contests are popular though, the mothers make mistakes and all laugh, and we have a lot of fun.

Dr. C: The best plan is to have the contest before the conference. In that way you have better interest and more mothers stay.

Dr. D: About 40 or 45 minutes is the optimum length of time for the contest. It doesn't work well if you take much more time than this. And each station should space them at least 3 months apart. You can't have the quizzes more often than that if you want to keep the mothers interested in the game. But 3 months is just about the right time to repeat the contest with the same mothers.

The discussion and the quoted comments and criticisms above, taken together, highlight the characteristics of a good contest. Briefly stated, these may be considered the following:

1. *Participation* by all who attend.
2. *Informality* and the "game" spirit.
3. *Emphasis* on subjects of current interest and also on subjects unknown or relatively unknown to the participants.
4. *Adequate discussion* and explanation of the reasons for the answers.

5. A *coördination and summary* (on the part of the physician) of the information brought out during the discussion.

6. *Length* not to exceed 40 to 45 minutes for maximum interest to the participants.

Through the use of the True-False contest in baby stations, one of the primary interests motivating mothers to attend child health conferences is satisfied. The mother's desire for service and information brings her to the station. Physical examination of the baby, and the physician's recommendations constitute the service, but the mother also receives information on maternal and baby care during the conference.

The health education technic described here can increase the amount of information about maternal and child hygiene which the mothers get and can also aid physicians to determine where teaching is most needed and how it will be most effective.

SUMMARY

1. An adaptation of the popular quiz program has been introduced in baby stations.

2. Quiz contests can assist a baby station physician in giving information about maternal and child hygiene and thus aid in educating mothers in adequate health procedures by a popular technic, new in the field of public health education.

3. By means of contests, both physicians and mothers learn. The physician finds what subjects of maternal and child hygiene require special emphasis because they are unknown or relatively unknown to the mothers—information that can be utilized in improving subsequent child health conferences.

4. How the contest is conducted depends principally upon the physician who serves as moderator and educator in the test situation. The amount of teaching done is directly related to the way in which the quiz period is handled by the physician.

5. Characteristics of a good contest are:

- a. *Participation* by all the mothers
- b. *Informality* and the "game" spirit
- c. *Emphasis* upon subjects of current interest and other pertinent problems
- d. *Adequate discussion* and explanation of reasons for answers
- e. *Coördination and summary*, by the

physician, of the information brought out during the discussion period.

f. Length not to exceed 40 to 45 minutes for maximum interest.

6. Contests not having the characteristics

above have little value in health education.

7. Although it has not been experimentally demonstrated, it is believed that variations of the quiz technic can be used in other types of public health clinics.

For frontier prayer when St. Louis was young was the Old Cathedral, which still stands on the river front.

Development of Tuberculosis and Changes in Sensitivity to Tuberculin in an Institution for the Feeble-minded*

A Ten Years' Study

DAVID ZACKS, M.D., AND PHILIP E. SARTWELL,
M.D., M.P.H.

State Department of Public Health, Boston, Mass.

IN 1930 a survey was made of the inmates of the Walter E. Fernald State School in Massachusetts, an institution for the feeble-minded, primarily for the purpose of studying the comparative sensitiveness of the Pirquet and Mantoux methods of tuberculin testing, but with a view also to determining the extent of the tuberculosis problem in this hospital.^{1, 2} All inmates were tuberculin tested and given an x-ray of the chest. Ten years later as many of these individuals as were still living at the school were reexamined to determine what changes had occurred in their sensitivity to tuberculin and in their x-ray findings. Both surveys were conducted by the staff of the Division of Tuberculosis, Massachusetts Department of Public Health, with the cooperation of the institution staff.

The number originally tested and x-rayed was 1,656, of whom it was possible to reexamine 1,023, in addition to reviewing the records of those who had died in the school during the interim. All inmates had been given an intracutaneous tuberculin test with 0.01 mg. of old tuberculin, and those who

failed to react had been retested with 1.0 mg. Unfortunately, a record was not preserved of the individual reactions to different dilutions of tuberculin in 1930, all reactors to either 0.01 mg. or 1.0 mg. being recorded as "positive" on the medical records. However, a table was available showing the distribution of positive and negative reactions to the two dilutions by age groups in 1930. The same technic of intracutaneous testing was followed in 1940 as closely as possible. In both surveys the tests were performed and reactions interpreted by physicians experienced in this work. It is recognized, however, that there were variables which could not be entirely eliminated, such as variations in the lots of tuberculin used and individual differences in the interpretation of skin reactions and reading of x-rays.

Owing to the lack of adequate facilities, inmates found to have tuberculosis could not always be segregated from others as completely as was desired, and it will be seen that the original non-reactors frequently developed a positive test while in the institution. For the purposes of this study we are not concerned with the 51 inmates found to have significant tuberculosis in 1930, of whom 34 were again x-rayed in 1940,

Mean age of inmates tested in 1930: 25.9 years

Mean age of inmates retested in 1940: 38.3 years

the other 17 having died. Also excluded from consideration were 14 cases reported to have died of tuberculosis whose 1930 x-ray films had been lost or destroyed, so that they could not be said with certainty to have been free from tuberculosis when first examined. For every person included in this study and classified as having died of tuberculosis or found diseased in 1940, we have the 1930 x-ray and have agreed upon reviewing it that the patient was free from pulmonary tuberculosis at that time.

An analysis of the results of the tuberculin testing by age in 1930 and 1940 is presented in Table 1. Each line in this table refers to a particular group of inmates; *e.g.*, the 43 children shown as having been retested in 1940 in the 15-19 age group are members of the group of 56 who were tested in the age group 5-9 in 1930. This arrangement was made to facilitate the comparison of the same groups over the period. This table shows that the individuals tested in 1930 now have a higher incidence of positive tests in each age group, as would be expected after an interval of 10 years. In order to compare the percentages of reactors in similar age groups at the time of testing, one should refer to Table 2, in which it is seen that for the same age groups the percentages were higher in 1930 than in 1940 up to

the fourth decade of life, after which they remained close to 100 per cent in both years. This also might be expected in view of the general reduction in tuberculosis morbidity and mortality in the community.

TABLE 2

Percentages of Reactors in 1930 and 1940 by Age at Time of Test

Age Group	Per cent of Reactors to 0.01 or 1.0 mg. Tuberculin	
	1930	1940
15-19	77	67
20-24	84	78
25-29	92	87
30-39	97	95
40-49	98	99
50 and over	95	99

Turning now to the study of individuals, we have shown in Table 3A what happened to those who failed to react to the test in 1930. Here the age groupings are those of the original test period. Of the 131 persons whose tests were negative in 1930, 72, or 55 per cent, became reactors over the 10 year period. The application of the Chi-square test to the series indicates that the differences in frequency of conversion of a negative to a positive test by age are not statistically significant and could be due to chance. The same is true of the difference by sex, as seen in Table 3B.

TABLE 3A

Findings on Retest in 1940 of Previous Non-reactors, by Age

Age (As of 1930)	Number Retested	Number Positive to 0.01 mg.	Number Positive to 1.0 mg.	Total Number Positive	Expected Number Positive	Per cent Positive
5-9	22	7	3	10	12.1	45
10-14	56	25	10	35	30.8	62
15-19	33	14	5	19	18.1	58
20 and over	20	4	4	8	11.1	40
All ages	131	50	22	72	72.0	55

Value of Chi-square=4.02.

Probability of this age distribution in conversion to a positive test occurring by chance is > 0.2 .

TABLE 3B

Findings on Retest in 1940 of Previous Non-reactors, by Sex

Sex	Number Retested	Number Positive to 0.01 mg.	Number Positive to 1.0 mg.	Total Number Positive	Per cent Positive
Males	93	39	16	55	59
Females	38	11	6	17	45
Difference (males-females)	14 ± 9.5

When we study the frequency with which tuberculin-positive individuals became negative, we find, as Table 4A shows, that the average frequency of reversion is 3.3 per cent over a 10 year period, but that the frequency is distinctly higher in the younger age groups. For all persons under 15, it is 12.7 per

cent; for those over 15, 1.7 per cent. The difference is 11.0 ± 3.0 , which is statistically significant. In other words, the excess in reversions of a positive test to negative among children is greater than one might expect from chance alone. Table 4B shows that males and females behaved alike in this respect.

TABLE 4A

Per cent dying of tuberculosis		2.9	...	0.4%
Difference (reactors-non-reactors)		2.5±1.0		

Tables 5 to 8 deal with the frequency of clinical tuberculosis in the group. Fourteen deaths during the 10 years were ascribed to tuberculosis. Autopsy was obtained in 6; positive sputum was reported in 3 others; in another group of 4, while no sputum reports are found, there were typical tuberculous lesions in the lungs by x-ray. The remaining case died after transfer to another institution, of tuberculous meningitis. One of the autopsied cases also died of meningitis.

Table 5 gives the age distribution of those dying of tuberculosis between 1930 and 1940, and classifies them according to their previous tuberculin reactions. It also shows the deaths as percentages of the number tested in 1930, or roughly as mortality rates. It should be realized, however, that the percentages given are not true mortality rates because the population at risk was declining somewhat during the period and was not equal to the original number tested; furthermore, the time interval was 10 times that conventionally used in computing death rates. It will be noted that the mortality rate over the 10 year period was significantly higher among previous non-reactors than reactors, and that the non-reactors who died were on the whole younger than the reactors; this latter finding is of course due to the fact that most of

the non-reactors were found in the younger age groups.

TABLE 6

Cases of Tuberculosis Discovered in 1940 Survey, by Age

Table 8 shows the intervals which elapsed between the study in 1930 and the time of death, for those inmates who died of tuberculosis after having had a normal chest x-ray. There were no deaths in the first 4 years; and the previous reactors appear, on the whole, to have died somewhat earlier than the non-reactors.

When the cases were classified by the hospital buildings occupied at the time of the 1940 survey, it was noted that 3 of the 7 living cases of tuberculosis first diagnosed at this time were from one section, North Building. The incidence here was 3 out of 116 x-rayed, as contrasted with 4 out of 907 x-rayed in the rest of the institution. Three of the 14 patients who died of tuberculosis prior to the 1940 survey were recorded as living in this same building at the time of the original survey.

Furthermore, out of the 116 resurveyed inmates of North Building, there were 13 non-reactors who became reactors, and the percentage of positive reactions, both for the entire building and within the age groups separately, was higher than in the rest of the institution. The median age of inmates of North Building was 21.6 as against 24.2 for the entire school.

The crude incidence of positive reactions was 96 per cent for North Building, and 90.8 per cent for the rest of the institution; this difference is statistically significant. It is also of interest that there were no reversions of a positive test to negative in this building. North

Building houses the male inmates of lowest mentality whose mental condition makes them least capable of observing rules of hygiene.

COMMENT

This group provided an unusual opportunity for investigation of the epidemiology of tuberculosis. Most similar studies are conducted with persons followed for varying lengths of time, which necessitates the use of a method of analysis based on "observation years" or the adaptation of the life table principle. Both of these methods are undesirably complex, and the observation years method fails to take into consideration varying degrees of risk to which persons may be subject at different periods after the beginning of observation. No such calculations were here necessary, because the entire group was followed for the same fixed period of time.

Our interpretation of the data on incidence of infection by age is that, for inmates under the age of 30 at least, the total exposure to tuberculosis in their homes and since entering the institution has been less than it was 10 years ago for the corresponding age groups. This requires the assumption that the 633 patients discharged, paroled, or dying subsequent to 1930, did not differ from those who remained, with respect to tuberculous infection. The figures also show, however, that fairly heavy exposure has continued within the school, for there has been a considerable increment of persons infected since 1930 in each age group up to 30 years of age. That the total exposure of this group has been greater than that of public school children, for example, is shown by Table 9, which contrasts them with other groups surveyed by the department.

Why the re-test should show a higher frequency of reversions from positive to negative in the younger age groups we cannot explain. More evidence to con-

TABLE 9

Comparative Results of Tuberculin Testing with 0.01 mg. O. T. in Massachusetts

firm or refute this finding should be obtained before an explanation is offered.

The higher incidence of tuberculosis in initial non-reactors was of particular interest to the authors because of our own studies indicating that public school children with a positive reaction develop tuberculosis more often than non-reactors.³ Many advocates of both views can be found; the majority probably look upon the uninfected person as showing a higher incidence. We do not feel that the results of this study are necessarily incompatible with those referred to above, because the groups studied differed widely in composition and environment. The public school children were living normal lives in an environment which usually afforded little exposure to tubercle bacilli, as shown by the small annual increase in percentage infected. In the Fernald School, on the contrary, there was heavy exposure, as indicated by the more rapid rise in the proportion infected with increasing age.

A hypothesis to fit these observations can be advanced with the aid of the following assumptions: First, that pulmonary tuberculosis can develop in the previously infected person, both from fresh infection or superinfection, and from endogenous reinfection. Second, that the previously uninfected person is more likely to break down than the infected one, when heavily exposed to

tuberculosis—that is, that old infection confers some protection against disease resulting from new exposure. Then one may expect that, in persons whose environmental contact with tuberculosis is heavy and continuous, most of the cases will develop among previous non-reactors; while among persons with little exposure, a relatively large proportion of cases will result from endogenous reinfection, the total number of such cases being of course much smaller than in the former group. In other words, among the public school children endogenous reinfection played a relatively important rôle, while in the Fernald School it was overshadowed by the part played by continued contact with tuberculosis. The percentage of reactors to tuberculin in the second and third decades is well above that encountered in other groups which the department has tested recently. The comparison is made on the basis of reactions to 0.01 mg. of tuberculin because of the fact that only this strength was used in the other groups.

It will be noted that the inmates were not classified and studied according to their exposure to tuberculosis within the institution. This was because it was not felt that such a classification could be made with accuracy in view of the presence of tuberculosis cases which could not be entirely segregated, and the poor hygiene practised by these patients.

Attention is called to two other recent studies which dealt with similar material. Flahiff⁴ found that among persons admitted to a mental hospital in Jamaica, B.W.I., where tuberculosis was prevalent, the rate of onset and the death rate from the disease were higher in those who did not react to tuberculin on admission than in those who were sensitive to tuberculin on admission. Plunkett, Weber, Siegal and Donk⁵ made an investigation of the inmates of a state school for mental defectives in New York State which showed a marked difference in the frequency of development of a positive tuberculin test and incidence of tuberculosis, depending on whether the individual was exposed to an infectious case. Every case of reinfection type tuberculosis which developed could be associated with the presence of an infectious case in its immediate environment. It was noted that the rate of change from negative to positive reactions was higher in all age groups among males. We found a similar sex difference in the total number of non-reactors who became positive, but it was not statistically significant.

SUMMARY AND CONCLUSIONS

Of 1,656 inmates of a school for feeble-minded who had been tuberculin tested and x-rayed in 1930, 1,023 were restudied in 1940. The percentage of

positive reactors was somewhat higher than in 1930, but when compared by age groupings at the time of the test, there was a slight falling off up to the age of 30.

Former reactors reverted to a negative state more often under the age of 15 than above this age. Tuberculosis developed most frequently, and conversions from a negative to a positive tuberculin reaction were most common among inmates of the building for patients of lowest mental status.

The subsequent incidence of tuberculosis was higher among those who failed to react to tuberculin in 1930 than among the reactors.

Food Establishment Sanitation in a Municipality*

FERDINAND A. KORFF, F.A.P.H.A.

Director, Bureau of Food Control, City Health Department, Baltimore, Md.

IT is true as Rosenau¹ has said that all public health work is based upon the four fundamental needs of human welfare, namely, food, shelter, defense, and propagation. The safeguarding of the food supply of a community, it appears then, is one of the essential functions of a health department. The responsibility for the inspection of food establishments in municipalities is almost invariably assumed by this department. In states, as well, this responsibility is generally vested in health departments.

The fundamental principles of sanitation of food establishments require that the protection of the health of the consumer against dangerous foods and the general cleanliness and appearance of the establishment be given first consideration. This combined activity requires all-out efforts of the food inspection personnel; it is not really a health department function to be active in preventing fraudulent trade practices.

Slack² has pointed out that during recent years the conception of the duties of the food inspector has undergone a great and important change. Whereas formerly his activity was largely devoted to the search for adulterated, spoiled, and unwholesome food, and prosecution of the dealer, the intelligent food inspector of today seeks to co-operate with the dealer to insure the

marketing of foods of high quality. It is, as he says, the joint responsibility of the producers, the dealer, and the inspector to see that the food offered to the public should not present a health hazard, whether from the viewpoint of containing disease producing organisms or from any other of the various ways in which food may be harmful to health.

PRIMARY OBJECTIVE OF FOOD ESTABLISHMENT INSPECTION

The primary purpose of food establishment inspection from the public health point of view is to prevent food poisoning and infections transmitted by food. In order to prevent illnesses the underlying causes must be known. Then there must be developed a practical procedure for applying the means of prevention.

To prevent food illnesses, the causes of which are given in Table 1, the combined sciences of bacteriology, chemistry, engineering, epidemiology, pedagogy, toxicology, and statistics must be applied. For example, in combating botulism, familiarity with both bacteriology and canning principles is necessary. Consumers and merchants must be informed of the necessity for destroying spoiled canned food. Cannery and housewives must be taught that specific times and temperatures must be adhered to for each product canned.

Familiarity with the Salmonellas, a study in itself, must be had. Havens³

TABLE 1
Causes of Food Poisoning and Infections

	<i>Foods Often Implicated</i>	<i>Usual Time of Onset</i>
<i>Of Bacterial Origin</i>		
<i>Clostridium Botulinum</i> toxins	Improperly processed canned and bottled food	12 to 24 hours
<i>Staphylococcus enterotoxin</i>	Custard pastries, cooked ham, hollandaise sauce, sliced cooked meats	3 to 6 hours
<i>Salmonella</i> infections	Sliced cooked meats, meat and poultry salads, "warmed over" foods, custard-filled pastries	6 to 18 hours
Enteric infections Typhoid fever Bacillary dysentery Tularemia	Oysters, raw milk, other dairy products Salads, "warmed over" foods, milk and other dairy products Wild rabbits (by handling)	3 to 38 days 1 to 7 days 1 to 10 days
<i>Of Nonbacterial Origin</i>		
Inorganic chemicals Arsenic, Lead Fluorides Antimony Cyanides Cadmium, Zinc Copper, Barium Others	Any food accidentally contaminated	Several minutes to hours, depending upon dosage
Poisonous animals and plants	Rhubarb leaves, mussels in certain seasons, poisonous mushrooms, poisonous fish	Variable
Animal parasites	<i>Trichinella</i> in pork <i>Diphyllobothrium</i> in some fish <i>Taenia</i> in beef	Several days to weeks
Allergies and environmental circumstances	Specific foods consumed by persons allergic to these foods Consuming food while exposed to dangerous gases (CO), high temperatures, etc.	Immediate to several hours

states, "No other group of bacteria, with the possible exception of the streptococci, present such a varied assortment of bacteriological problems, pathological manipulations, and epidemiological peculiarities as do those closely related bacteria of which the paratyphoids may be taken as the type." Preventing the *Salmonella* type of food poisoning requires teaching skill. Public health educational methods must be applied to teach individuals and groups of food handlers to keep clean, to bring into use ample lavatory facilities conveniently installed, and to bring about efficient refrigeration of ready-to-eat foods. In this latter effort, the fundamentals of refrigeration must be known;

often it is extremely advantageous to call upon the engineer for specific instruction in refrigeration engineering.

In order to prevent infections of food by the enterotoxin producing *Staphylococci*, it must be recognized that open sores and skin abrasions in food handlers are possible sources of these organisms. The reheating of custard-filled pastries as suggested by Stritar, Dack, and Jungewaelter,⁶ and Gilcreas and Coleman,⁷ must be explained in detail to bakers. Chefs in hotel kitchens must be taught the reason why hollandaise sauce should be discarded within 4 or 5 hours after it has been made. Meat plant operators under both federal and municipal supervision must be con-

vinced that the newer type of ready-cooked and tenderized hams should be processed, prepared, and wrapped with a minimum amount of hand contact, and that regular medical inspection for skin abrasions should be maintained for all persons touching this type of food.

While the investigation of cases and outbreaks of typhoid fever and dysentery is the duty of the epidemiologist, material aid can frequently be given by the food inspection personnel, particularly in preventing recurrence of these diseases. A review of records of receipts and sales of shellfish dealers facilitates tracing shellfish to their source if this food is implicated. Known typhoid fever carriers must be convinced of the danger of handling food intended for others and for the need of voluntarily withdrawing from such activities. Dysentery infections may be prevented by applying the same methods as for the *Salmonella* infections. Tularemia can be prevented by banning the sale of wild rabbits. The enforcement of this prohibition requires the patrolling of railroad and truck terminals and wharves during certain seasons and can be carried out along with the enforcement of the compulsory shellfish certification requirement. All milk sold in a municipality should be pasteurized under the supervision of personnel trained for this duty.

Food illnesses caused by poisonous chemicals can be prevented by equipping the food inspector with simple testing outfits. Fluorides, arsenic, and cyanides can be detected readily by means of such portable equipment. Enforcing restrictions against the use and sale of fluorides, except of the tinted variety, prohibiting the use of cyanide-containing metal polishes in food establishments, and advising against the use of bare copper, galvanized and cadmium-plated, and some types of gray agateware food containers, and poisonous chemicals employed as insect and

rat eradicators, should be a part of the daily routine in guarding against food contamination by poisonous chemicals.

The importance of thorough cooking of pork and some fresh water fish should be explained to food merchants and consumers and also to civic, educational, and religious organizations, as an effective means of preventing illnesses caused by parasites found in these foods.

Information concerning poisonous plants and animals, the fact that food consumed under certain unfavorable environmental conditions may cause symptoms resembling food poisoning, and that certain individuals may be allergic to some wholesome foods, should be emphasized to food merchants and consumers at group meetings.

COÖPERATION WITH FOOD INDUSTRY ESSENTIAL

It is essential that the coöperation of representatives of the food industry and others be obtained, for it can readily be seen that in attempting to protect the consumer against the food-borne diseases, education and coöperation are the principal weapons of the health officer. Except in some instances, as for example, the prohibiting of the sale of wild rabbits to prevent tularemia and cyanide silver polishes in food establishments, legislation cannot be used as the only preventive measure. The food handler must be instructed in the fundamentals of food sanitation. Education of the employed food handler, however, can be effective only when the owner of the food establishment endorses such a procedure. The effectiveness of compulsory medical examination of food handlers is still debatable among public health officials, with the majority apparently not in favor of this costly procedure. Education of food handlers seems to be supplanting this old-time practice. The reheating of custard-filled pastries, exerting care in ham processing and handling, and the washing of hands

after leaving the toilet require the wholehearted interest and coöperation of the industry with the health official. Supervisory personnel of organizations within the food industry can be trained in relatively short periods of time and used as unofficial food inspectors of their own organizations and, with the coöperation of the industry, can be of valuable assistance as liaison personnel between the official inspector, the food handler, and the management.

It is most important that regular contacts be maintained with state and federal food control officials and neighboring municipal food inspection personnel. Regular scheduled meetings should be planned, at which time experience during inspections, results of special investigations, new legislation, and new methods should be reviewed and discussed.

In obtaining corrections of undesirable conditions relating to food establishments, it has been found also that educational methods are by far the most effective way to obtain results. This method is one of the three mentioned by Rosenau,¹ "There are three ways of obtaining results, (1) through military or arbitrary ways; (2) through legislative or punitive ways; and (3) through the establishment by education of standards through group consciousness." Modern public health administrative efforts are apparently leaning toward the last method. This is as it should be. Modern police departments have adopted educational procedures as aids in enforcing certain laws and in crime prevention. The interest of a coöperative public can be capitalized to aid in effecting corrections of undesirable conditions that would be difficult to obtain by compulsion. Included in the coöperative public groups, of course, are members of the food industry. An educational procedure that has proved effective is the semi-regulatory one that combines regulatory action with education,

namely, that of health department hearings. At the conference or hearing, past and current findings during inspections are brought out, and instruction, advice, and warnings as needed are given to the individual or entire industry directed to appear for such conferences.

GROUPING OF FOOD ESTABLISHMENTS

For ease of assignment and inspection, it has been found by over ten years' experience that it is expedient to group food establishments located in a municipality into three classes: (1) wholesale, (2) manufacturing, and (3) retail. Food manufacturing establishments include bakeries, canneries, dairies, refineries, and other factories of this type. Warehouses, railroad terminals, wharves, cold storage plants, etc., comprise the wholesale establishments. Under retail establishments are included kitchens of schools, hospitals, homes for the aged and orphanages, retail markets, food stores, restaurants, hotels, and similar establishments. This grouping of food establishments creates a first, second, and third line of defense respectively against unwholesome food reaching the consumer.

ASSIGNMENTS FOR INSPECTIONS

It has been found in large municipalities that assignments for routine inspections by census tract subdivisions of the community result in more effective coverage of all retail food establishments. The use of census tracts as small units or as individual communities also aids in obtaining information concerning improvements in food establishment sanitation from year to year, and makes statistical analyses of results more profitable.

ESSENTIAL FORMS

A duplicate inspection record form has been found to be convenient* and serves the threefold purpose of (1) pro-

* Samples obtainable from the author.

viding a means of giving written instructions to the food establishment owner; (2) providing a permanent file record of the findings during inspection, eliminating the necessity of posting to a second form inspection findings; and (3) supplying the information on the copy for transfer to a punch card where desirable.

ALLIED ACTIVITIES

In addition to the basic duty of maintaining inspection of food establishments to prevent food illnesses, and to maintain them in a good sanitary condition, a food control bureau must necessarily engage in other activities. Filth in food should not be tolerated, regardless of the fact that it may be harmless. A project on this activity carried to completion is valuable in sensitizing the food industry against carelessness. Adulteration, misbranding, and mislabeling of foods must not be entirely overlooked, but when found it is more expedient to report these findings to state or federal agencies for action by those who are primarily responsible for this type of activity.

Food utensil washing and disinfection must be given consideration and should be a basic and continuous project. Each inspector should be trained to determine rinse water temperatures in dish washing machines, to test the strength of chlorine solutions, and to be able to swab food utensils without contamination of the swab. A compact food utensil swabbing bottle for this purpose has been described.⁸

Complaints pertaining to food or food handling methods must be investigated quickly and given immediate attention to be of value in correcting undesirable conditions in a community. While it is admitted that often only 10 per cent of the complaints are justified, these 10 per cent often lead to corrective measures being applied to all food establishments in the community.

Dual water supplies, cross-connections, inadequate ventilation and lighting, garbage and waste disposal, insect and rat eradication, occupational hazards among food handlers, reviewing plans for new plants and alterations to existing plants are other problems that must receive attention. In all of these additional activities no attempt should be made to operate without aid from other bureaus or divisions within the health department or in the state health agency. In the investigation of food poisoning outbreaks it has been found that a team of investigators consisting of a physician, usually the epidemiologist, a bacteriologist or chemist or both, and the food official, facilitates intelligent interpretation of findings and eliminates a great deal of unnecessary laboratory work. Preferably the physician connected with the health department should make the contact with the physician attending the ill persons; the food official or physician may obtain information from the individual cases and may secure all samples of food available and of body discharges. No sample is submitted for laboratory examination until the findings and facts are reviewed by all members of the team, and only the food or foods common to all of the persons made ill are submitted for bacteriological or chemical analyses.

In the investigation of dual water supplies and cross-connections a sanitary engineer should be consulted. In occupational hazards the occupational disease physician, if available in the health department, is called upon for aid. Ventilation, lighting, and garbage and waste disposal are types of problems which should be discussed with industrial hygiene or sanitation personnel of the department.

TRAINING OF PERSONNEL

Regardless of the basic training of the food establishment inspector, in-service

instruction is needed as a constant supplement. Chemists, bacteriologists, and sanitary engineers are scientifically trained for this type of position, yet in-service training must be continued during the entire period of actual duty. As an example, the science of nutrition must be taught to the basically trained food inspector. The fortification of milk and other foods has a certain popularity. It leads to advertising racketeering and therefore has not especially endeared itself to some public health officials. The newer findings in food sanitation must be taught and research problems, even in food inspection activities, should be planned and discussed as part of the in-service training.

SUMMARY

Food inspection in a municipality has developed into a comprehensive field, requiring knowledge of the causes of food poisoning and food infections and utilizing all of the sciences practised by public health officials in preventing these illnesses and in maintaining the food establishment in a clean condition. The corrective measures employed include educational methods in the main. The coöperation of all public health, industrial, and lay agencies is of importance in this educational procedure.

Economic aspects of food control, while desirable, should be given secondary consideration over those of more public health importance.

Record keeping should be simple; punch cards and sorting machines are recommended where the numbers of

records warrant. Assignments by census tracts should be made, keeping pace with the best health department practice. Personnel adequately trained in bacteriology, chemistry, and sanitary engineering only should be employed for food establishment inspections. In-service training must be continued regardless of the basic training of the employee.

In food establishment inspection, as in all public health work, the population of the community should be studied. Procedures that are to be employed to prevent food poisoning and undesirable conditions in food establishments should fit in with the temperament of the community. A health-conscious community will usually respond to educational methods sponsored by the health department. The procedures mentioned are those that can be adopted in a moderately large community or modified for smaller communities.

A Simplified Medium for Pathogenic Organisms

N. GROSSOWICZ AND ISRAEL J. KLIGLER,
Ph.D., F.A.P.H.A.

Department of Hygiene and Bacteriology, Hebrew University, Jerusalem

THE recent advances in our knowledge of the nutritional requirements of bacteria have opened the possibility of simplifying the standard media at present in use in bacteriological laboratories. The obstacle in the path of such simplification is the fact that each of the more parasitic forms has specific requirements of its own, and consequently it is not easy to find an extract which will combine the accessory substances found both in meat extract and in serum.

This note reports our experience with a new medium, relatively simple in composition, easy to prepare and satisfying the requirements of some of the more fastidious organisms encountered in daily work. It is the by-product of studies now in progress on the growth accessory substances for *Streptococcus hemolyticus* and *Pneumococcus*.

The medium consists of the following ingredients:

A. Peptone—Salt Solution

Peptone (Difco)	5.0 gm.
NaCl	5.0 "
Na ₂ HPO ₄ · 12H ₂ O	2.5 "
KH ₂ PO ₄	0.35 "
MgCl ₂ · 6H ₂ O	0.3 "
H ₂ O	1,000 ml.

B. Tomato Juice 40–60 ml.

Solution A is prepared in the usual way and autoclaved. If an agar medium is desired, 20 gm. of agar are dissolved in a portion of the water and added to the hot peptone salt solution before

autoclaving. To the sterile liquid or solid medium are added 4 to 6 per cent of a sterile extract of tomatoes (Solution B).

The tomato extract is prepared from fresh, washed tomatoes (preferably the variety used for juice) either by a juice press or by passing them through a meat grinder. The watery pulp is filtered through filter paper. The clear filtrate is neutralized to pH 7.0 (usually 6.0–7.0 ml. N/1 NaOH is required to 100 ml. of filtrate), and sterilized by steaming in the Arnold sterilizer or by filtering through a Seitz filter.

The original filtrate has a reaction of pH 4.2 and if left unneutralized can retain its activity for months. It is best, therefore, to sterilize it before neutralizing and to add the requisite amount of NaOH as and when required. Steaming in the Arnold or boiling for a few minutes does not reduce appreciably the activity of the extract; autoclaving, however, destroys a large part of the activity.

Tomato juice is fairly rich in accessory substances needed by bacteria, such as thiamin, riboflavin and nicotinamid, as well as in some other substances not yet identified. It has been used before as a source of growth accessory substance. Thjötta and Avery (1921) used it as a source of factor "V" for *Hemophilus influenzae*. Jenkins (1923) recommended its use for the cultivation of streptococci; the proposed medium

did not prove satisfactory presumably because the author autoclaved the extract and thus destroyed the major portion of the accessory substance. Kulp and White (1932) used it for growing lactobacilli by adding 40 per cent tomato juice to a peptonized-milk-peptone medium.

Our medium has many advantages over the standard medium used at present. It is very easy to prepare. There is considerable saving of time—since no clearing or filtering of the medium is necessary. It is much less expensive than meat extract or meat infusion media. And finally it is suitable for growing some organisms which do not grow readily on standard broth or agar. In addition to the easily cultivated colon-typhoid group of bacteria, *Brucella*, *Pasteurella*, *Lactobacillus*, *Streptococcus*, *Pneumococcus*, and *Corynebacterium*

diphtheriae give good growth on this medium.

Comparative growth tests made in the tomato medium and in standard laboratory broth or broth plus serum showed up to the advantage of the first. Tubes containing the same volume of nutrient solution were given equal small inoculations (0.1 ml.) from the same diluted saline suspension of bacteria prepared from a 24 hour agar-slant culture. After incubating for 20 or 40 hours, the respective tubes were centrifuged at high speed to obtain complete sedimentation, the sediments resuspended in 5.0 ml. saline and the relative density determined in the photoelectric colorimeter (Evelyn 1936). The results of one series of experiments are given in Table 1.

These figures show clearly that the proposed medium is not only superior

TABLE 1

Relative Growth Densities of Various Organisms in Standard Broth, Serum-broth, and Tomato Juice Broth (T.J. Broth)

Culture	Medium	Colorimeter Reading (100=No Growth)	
		20 hr. Growth	40 hr. Growth
1. <i>Streptococcus hemolyticus</i> H 7276	{Broth Broth + 10% serum T.J. broth	97 80 90	96 79 69
2. <i>Streptococcus hemolyticus</i> (Richards strain H. McIlwain)	{Broth Broth + serum T.J. broth	97 74 71	97 76 64
3. <i>Pneumococcus</i> H 6480	{Broth Broth + serum T.J. broth	96 71 77	93 83 35
4. <i>Corynebacterium diphtheriae</i> (gravis)	{Broth Broth + serum T.J. broth	89 85 85	60 48 43
5. <i>Pasteurella leptiseptica</i>	{Broth Broth + serum T.J. broth	99 96 97
6. <i>Lactobacillus</i>	{Broth T.J. broth	72 46
7. <i>Escherichia typhi</i>	{Broth T.J. broth	57 35
8. <i>Shigella dysenteriae</i> (Shiga)	{Broth T.J. broth	72 49
9. <i>Brucella abortus</i> I	{Broth T.J. broth	96 78
10. <i>Brucella abortus</i> II	{Broth T.J. broth	88 83

to the more expensive standard broth, but that it generally is as good as or better than broth containing 10 per cent serum. The results on solid media parallel those in fluid media but do not lend themselves to quantitative comparison.

The results given above are typical of those obtained with a large series of strains from different sources. Tests were also made with a variety of obligatory anaerobes. Growth in McIntosh anaerobic jars on the T.J. agar was as good as on 1.0 per cent glucose-blood agar, but was better than that on 1.0 per cent glucose-agar.

This medium has also proved satisfactory as a basis for a variety of special media:

1. Addition of 10 per cent blood gives an excellent medium for cultivating *Neisseria* and *Hemophilus*.

2. It is as good as Loeffler's medium for cultivating *Corynebacterium diphtheriae* from swabs. Tests made in our diagnostic laboratory with 100 routine swabs gave the same results as Loeffler medium, and because of its transparency the colonies on this medium can be more readily differentiated from those of other organisms. Toxin production appears to be as good as on other media, but no quantitative test has as yet been made.

3. The addition of minimal amounts of tellurite 0.03–0.04 per cent to this medium offers a satisfactory differential medium for the various sub-types of *Corynebacterium diphtheriae* as well as for the common diphtheroids. Xerosis and Hoffmanni are readily differentiated from true diphtheria organisms. After 48 hours mitis can be differentiated from gravis and intermediate, but the last two are not readily distinguished.

Corynebacterium xerosis, gives heavy growth, black colonies.

Corynebacterium hoffmanni, slight growth, colorless colonies.

Corynebacterium diphtheriae (gravis), medium sized greyish colonies with a dark center.

Corynebacterium diphtheriae (mitis), small colonies, black with only a slight greyish rim.

4. Both MacConkey and Kligler medium can be readily prepared with T.J. agar as a base.

SUMMARY

This note presents a new basic standard medium which has many advantages over the one at present in use in bacteriologic laboratories. It is a simpler medium, more easily prepared with considerable saving in time and materials. It supports growth of all common pathogenic bacteria as well as many of those having special requirements, such as the streptococci, pneumococci, diphtheria bacilli, and lactobacilli. The *Neisseriae* do not grow on this medium without the addition of blood.

This medium can also be used as a base for the common differential media: tellurite for diphtheria, the various typhoid media, etc.

This medium is at present in use in the army laboratories in Palestine, and in our own class work.

Recommended Qualifications for Public Health Nursing Personnel*

1940-1945

SINCE the publication of "Minimum Qualifications for Those Appointed to Positions in Public Health Nursing" in 1936,[†] far-reaching developments have taken place that need to be considered in setting new goals for the next five years. The years 1935-1940 have seen the greatest expansion of public health nursing in its history, due in large part to the health provisions of the Social Security Act. Despite the pressing need for nurses to fill available public health nursing positions, there has been an increasing appreciation by administrators of the importance of appointing nurses specifically prepared for the public health nursing field. The Social Security Act has assisted in this trend by making provision for many nurses to get the needed preparation as well as requiring through a later amendment that appointments be made under a merit system of personnel administration.

The completion of the revised *Curriculum Guide for Schools of Nursing* by the National League of Nursing

Education in 1937 has given impetus to the enrichment of the undergraduate curriculum so that the nurse may be more adequately prepared to make her contribution to the health and social welfare of the community in whatever field she enters. However, since this requires a faculty prepared to assist in the integration of the health and social aspects of nursing throughout the curriculum, emphasis has been placed increasingly on the importance of faculty preparation in these areas by many schools. Also, it is apparent that the graduates from the schools which offer such an enriched curriculum, with a wide range of clinical experience including communicable and mental diseases, will be considered potentially the most promising for public health nursing service. The membership list of the Association of Collegiate Schools of Nursing and the National League of Nursing Education's list of accredited schools will be helpful in furnishing another basis for the selection of graduate nurses for public health nursing.

The growth of merit systems as a method of selecting personnel both in official and nonofficial agencies has made for greater understanding by agencies and by citizens of the need for specific requirements for the various positions in the field of public health nursing. The qualifications recommended here have been formulated in the light of these present trends in qualifications for public health nurses wherever they may be employed.

Determined effort to reduce further

* Preliminary Report of the Subcommittee on the Educational Qualifications of Public Health Nurses of the Committee on Professional Education, American Public Health Association.

This Report has been approved by the Education Committee of the National Organization for Public Health Nursing and by the Committee on Professional Education of the A.P.H.A. It is published here to permit the members and Fellows of the Association to review it and to offer criticisms and suggestions prior to its further consideration.

This Report, like all other statements of the committee, on professional and technical qualifications in public health, is subject to periodic revision in order that it may be kept abreast of the best thought.

[†] Published in *Public Health Nursing*, March, 1936, (page 172).

certain existing health problems, such as crippling in children, maternal and neonatal hazards, tuberculosis, and the venereal diseases, has made emphasis on special services in these areas necessary. Each of these is recognized as one part of the whole family health service, and, as such, is most adequately carried on by the field nurse who is responsible for all phases of the public health nursing program. The nurse, however, needs help from consultants who in addition to the necessary equipment as supervisors have had preparation in the special field in which they are engaged.

Mindful of these trends and realizing that the first principle underlying the improvement of service is the appointment of qualified personnel, the Education Committee of the National Organization for Public Health Nursing and the Committee on Professional Education of the American Public Health Association recommend these qualifications for those appointed to public health nursing positions as the goal for 1945. They are based on the principles: (1) that one of the most essential requisites in public health nursing is the ability to work effectively with people, (2) that the public health nurse must be a competent nurse with sound basic theoretical and clinical preparation in nursing and with an understanding of its social and health aspects, (3) that additional study, including supervised field experience, is essential to prepare the graduate nurse for the specific functions of public health nursing, (4) that continued in-service education including qualified supervision (see II, A of outline) is necessary to further the development of the nurse's potentialities for improved service to the individual family and community, which is the goal of all public health nursing.

PERSONAL FACTORS IMPORTANT

While the following qualifications may

seem to stress academic preparation and professional experience, personality remains a major factor in successful public health nursing service, and therefore must always be given due consideration. Also, good physical health as determined by a preemployment examination should be considered essential because without it the other qualifications are rendered less effective.

Improvement in the technic of personal interviews and the collection of credentials, through study of personnel methods in other fields, will help in developing more accurate methods for the selection of applicants with fundamental requisites. Tests and other measurements need to be studied as a means of determining individual abilities and capacities.

On the other hand, it is important for both the nurse and the employer to understand the purpose and value of theoretical preparation for public health nursing. University study should be an economical means to the end of greater competency in daily work and not an end in itself. It is a means for the nurse to review under guidance past and present practice in this field in order to become familiar with sound, workable principles and thereby avoid some of the trial-and-error learning common to all new workers. It is an opportunity to gain additional tools, both in content and method, which will make work in the field more pertinent and more productive.

Unusual competence in the work to which the nurse is assigned is the only sound basis for promotion to greater responsibility, and the one most frequently used. Well utilized graduate study should assist in the development of such competence. The amount of study suggested in these recommended qualifications is believed to represent the minimum needed for each type of worker described.

While these qualifications apply spe-

cifically to new appointees, the importance of corresponding additional preparation for those already appointed should receive careful consideration in relation to each nurse. Under certain conditions, it might be desirable for agencies to adopt a policy urging those appointed within the last few years to meet within a specified period of time the recommended theoretical preparation for the respective positions.

I. STAFF NURSES*

A. For the nurse working on the staff of an official or private agency under the direct supervision of a nurse supervisor who meets the qualifications herein set forth—

Duties: To carry on the direct nursing service of the agency in the home, clinic, conference, school, or industry.

Preparation:

1. General education—High school graduation or its educational equivalent which meets college entrance requirements. Education on a college level is desirable.

2. Basic nursing education—Graduation from an accredited† school of nursing connected with a hospital having a daily average of 100 patients, with the necessary affiliation, which gives the nurse a broad clinical experience in medical nursing, including acute communicable disease, tuberculosis, and the venereal diseases; psychiatric and pediatric nursing (including the care of children with orthopedic and cardiac conditions); and an understanding of the social and health aspects of nursing, both physical and mental, through an integrated program of instruction in

classroom, ward, outpatient department, with appropriate use of community facilities.

3. State registration.

4. Postgraduate study—Completion of the year's program of study in public health nursing in a university program approved by the National Organization for Public Health Nursing, previous to or within five years after appointment.

B. For the nurse in an official or private agency not working under direct supervision—

Duties: In addition to carrying on the direct nursing service of the agency as in A, to assist in organizing the service; to work with lay and professional groups; to carry on the activities in special situations such as the school and industry.

Preparation:

1. General education—Same as listed for staff nurse under A.

2. Basic nursing education—Same as listed for staff nurse under A.

3. State registration.

4. Postgraduate study—Completion of the year's program of study in public health nursing in a university program approved by National Organization for Public Health Nursing, before appointment.

5. Experience—At least one year's experience under qualified nursing supervision in a public health nursing agency in which family health is emphasized.

II. SUPERVISORS AND EXECUTIVES

A. For the supervisor—

Duties: To supervise the staff nurses in an official or private agency and to assist in their growth and development; to plan and develop the nursing program for which she is responsible in relation to the total program of the agency; to correlate it with that of other agencies in the educational, social, and health fields; to study and evaluate the program within her own area.

* See Minimum Qualifications for Nurses Appointed to School Nursing Positions. *Pub. Health Nurs.*, Feb., 1938, p. 169. Also Desirable Qualifications of Nurses Appointed to Public Health Nursing Positions in Industry. *Pub. Health Nurs.*, July, 1939, p. 410 and *A.J.P.H.*, 29, 7:789 (July), 1939.

† Accredited by the state board of nurse examiners.

Preparation:

1. General education—College degree.
2. Basic nursing education—Same as listed for staff nurse under I, A.
3. State registration.
4. Postgraduate study—Same as listed for staff nurse under I, B., and in addition, a course in principles of supervision.
5. Experience—At least two years' experience, one of which was under direct, qualified nursing supervision in a public health nursing service in which family health is emphasized.

B. For the consultant—

Duties: To assist in analyzing the needs and developing the service in the special field; to correlate this service with other services offered by the agency and with the programs of other agencies; to advise regarding policies, technics, and procedures in the special field; to participate in the supervisory and staff-education program of the agency in cooperation with the other supervisory personnel.

Preparation:

1. General education—College degree.
2. Basic nursing education—Same as listed for staff nurse under I, A.
3. State registration.
4. Postgraduate study—Same as listed for staff nurse under I, B., and in addition a course in principles of supervision and advanced preparation in the special field, including content in that field, courses in general education, and methods of making and using studies.
5. Experience—At least two years' experience, one of which was under direct, qualified nursing supervision in a public health nursing service in which family health is emphasized, and at least one year's experience as a generalized supervisor.

C. For the educational director or instructor in public health nursing—**Duties:**

In public health nursing agencies—to plan and to direct the educational program for the new nurse, for the student, and for the staff as a whole, and to correlate and develop the resources of the agency and of related community services for teaching purposes.

In schools of nursing—to assist in directing, to correlate, and to participate in the efforts to give the undergraduate student the concept of the social and health aspects of nursing, both physical and mental, through an integrated program of instruction in classroom, ward, and outpatient department, with appropriate use of community facilities.

Preparation:

1. General education—College degree.
2. Basic nursing education—Same as listed for staff nurse under I, A.
3. State registration.
4. Postgraduate study—Same as listed for staff nurse under I, B., and in addition, courses in principles of supervision and in the philosophy and principles of education.
5. Experience—At least two years' experience, one of which was under direct, qualified nursing supervision in a public health nursing service in which family health was emphasized, and at least one year's experience as a supervisor in a public health nursing service.

D. For the director—

Duties: To administer the nursing service of the official or private agency; to determine with the administrative official or the board the policies and program to be followed; to interpret the needs of the nursing service to the administrative officials, to the board, to committees, and to the community; to participate in community planning and action in health and social welfare.

Preparation:

1. General education—College degree.
2. Basic nursing education—Same as listed for staff nurse under I, A.
3. State registration.

4. Postgraduate study—Same as listed for staff nurse under I, B., and in addition, courses in supervision and in principles of administration.

5. Experience—At least three years' experience, preferably in more than one type of agency—i.e., official and private—including experience in supervision.

E. For the director of a university program of study—

Duties: To assume direct responsibility for the planning and administration of the program.

Preparation:

1. General education—Graduate degree.

2. Basic nursing education—Same as listed for staff nurse under I, A.

3. State registration.

4. Postgraduate study—Completion of the year's postgraduate program of study in public health nursing in one of the university programs approved by the National Organization for Public Health Nursing, before appointment, and advanced university courses in general education and in supervision and administration in public health nursing.

5. Experience—A minimum of five years' public health nursing experience, preferably in more than one agency,

one year of which should have been in a general public health nursing agency with direct, qualified supervision, emphasizing family health. This experience should include experience as a staff nurse and experience as a supervisor, executive, or educational director.

Public Health Activities Against Tuberculosis in Mexico*

VICTOR FERNÁNDEZ MANERO, M.D.

Chief of the Federal Department of Health in Mexico, Mexico City

WITH its wide variety of living conditions due to altitude, variations in rainfall and other conditions governing agriculture and industries, Mexico has a broad range of tuberculosis rates. The problem can best be

does not greatly exceed the number of deaths for the same period.

TABLE 1

Tuberculosis Mortality in Mexico

Years	Pulmonary	All Forms
1922	68.23	78.83
1923	27.34	76.06
1924	59.30	68.70
1925	66.28	74.67
1926	58.84	67.22
1927	60.21	66.34
1928	60.80	67.01
1929	61.02	67.67
1930	61.42	68.71
1931	61.82	70.03
1932	74.84	65.72
1933	55.16	61.66
1934	38.16	52.68
1935	39.13	54.27
1936	39.37	54.08
1937	39.36	54.09
1938	55.38

evaluated by a study of the death rates of the country as a whole and of the individual states. In general, the high rates are found along the coast of Mexico and along the northern border, while lower rates are the rule in mountain states. Death rates are higher in the large cities than in the smaller towns, with the exception that mining districts often present higher rates than the agricultural regions around them.

Little can be learned from a study of morbidity as yet, for even in the capital the number of reported cases

* Read before the Health Officers Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

TABLE 2

Tuberculosis Mortality in the Federal District

Years	No. of Cases Registered	Deaths	Death Rate Per 100,000
1934	1,036	1,301	88.11
1935	1,082	1,345	87.89
1936	1,801	1,312	82.73
1937	2,236	1,370	83.36
1938	1,868	1,417	83.19
1939	1,647	1,473	83.44

Some information is contributed by surveys with the use of tuberculin to determine the number of sensitive individuals. The greatest number of these tests has been made in children up to the age of 14 years, using the von Pirquet technic. Three such surveys gave the following results: one of nearly 20,000 school children, one of 4,224, and another of 861 children, all in Mexico City, gave the same percentage of positives, 52 per cent. Results for specific ages are not available. In another series, 14,131 children attending child hygiene centers in Mexico City were tested with the results shown in Table 3.

Of the children with positive von Pirquet who were subsequently exam-

TABLE 3

Tuberculin Test (von Pirquet) in Infants

Age-Years	No. of Infants Tested	Per cent Positive
0-1	11,036	1.6
1-2	2,087	4.6
2-3	164	11.0
3-4	283	14.8
4-5	297	17.8
5-6	239	15.6
6-7	25	20.0

ined by x-ray, 0.4 per cent were found to have active tuberculosis.

Measurements of sensitivity to tuberculin have been made on a limited scale, and they show something of the prevalence of infection with tuberculosis in the capitals of five states, Veracruz, Morelos, Hidalgo, Mexico, and Michoacán, in all of which tests were made with the same technic. A single injection of 0.1 of a 1 to 10,000 dilution of old tuberculin prepared by the National Institute of Hygiene was injected intradermally, and readings were made 48 hours later.

The percentage of positives obtained varied in the age group 5-9 years from 17 per cent in Toluca and Morelia to 28 per cent in Pachuca; in the adolescent group, ages 10-14 years, from 28 per cent in Morelia to 41 per cent in Pachuca; in the young adults, ages 15-29, from 36 per cent in Morelia to 60 per cent in Jalapa; and in the age group 30 years or more from 59 per cent in Morelia to 97 per cent in Jalapa. The numbers examined in these age groups were: in Pachuca 4,264, in Morelia 2,418, in Cuernavaca 366, in Toluca 423, and in Jalapa 622.

Studies of the mortality rates and the scattered tuberculin test indicate that two features which are commonly found in other countries are true of the tuberculosis problem in Mexico; the age group most affected is that of young adults, from 15 to 30 years; and peasants who move to the crowded cities apparently show a greater susceptibility to tuberculosis than those born in the city environment.

These data give a rough sketch of the present tuberculosis problem. Speculation with reference to the causes of low mortality in certain regions and high mortality in other regions may well be postponed until more epidemiologic information is available. In the meantime we shall discuss the steps which have been taken in the past to

attack the problem and the recent developments which are intended to provide us with additional knowledge and additional facilities for the control of the disease.

Organized efforts for the reduction of the incidence of tuberculosis have been in operation for about 10 years. The leadership of the agencies involved has been, during the entire time, in the hands of the Division of Tuberculosis of the Federal Department of Health. Responsibility has been shared with the Departments of Public Welfare and Education. In addition, private initiative is represented by a National Tuberculosis Committee. Coördination between governmental and private agencies is assured by the position of the Federal Director of Health as ex officio President of the National Tuberculosis Committee. Yet this committee is autonomous and has its own Board of Trustees, its Bureau of Technical Advisers, its Information and Propaganda Bureau and its Finance Committee, and it has complete responsibility for the handling of its own funds.

The earlier years were devoted to developing the internal organization of the governmental entities associated in the work, to the establishment of the first dispensaries and hospitals, and to the development of clinical methods which would be most effective for large scale operations. During those years the National Tuberculosis Committee was relatively inactive. With the beginning of 1941, the time appeared ripe for the public to take a more direct part in financing anti-tuberculosis activities and there was inaugurated an active campaign which has brought subscriptions of nearly 4,000,000 pesos for the construction of new institutions. The committee recognizes the uncertainty which is associated with occasional drives to obtain financial support, so it is now studying means for obtaining a more regular income with

general participation of all social groups. It has under consideration stamp sales and also a plan for general insurance with special reference to tuberculosis.

The facilities already available for handling cases of tuberculosis include about 1,000 beds in public hospitals, and 100 in private institutions. There are 8 dispensaries for ambulant cases in Mexico City and 25 in the remainder of the Republic. There is also in operation a preventorium of 50 beds maintained by the Federal Department of Education in one of the suburbs of the capital. For a more indirect attack on the problem, systematic educational work is being done by the Department of Public Health in coöperation with the Federal Department of Education. The Department of Labor is taking measures to improve working conditions in industrial districts. The department of Agriculture is encouraging the development of family gardens and the use of more adequate diets in rural territory. The Department of Public Welfare is taking measures to improve the diet of the city residents, including the establishment of large low cost restaurants under the supervision of trained technical personnel. The National Committee on Housing and other organizations are fighting overcrowding and other unhygienic features of home construction. There are other institutions which have great potential value in the fight against tuberculosis and are now ready for mobilization in the attack. Among these are 289 centers of hygiene and health units with 443 physicians and approximately 1,500 nurses and also the coöperative medical groups organized by the Department of Health among small farmers. There are 121 of these groups, with 170 physicians, 10 dentists, and 225 nurses. For case finding and follow-up work in the homes, these groups will be of the greatest value when there

are more adequate facilities for treatment. Naturally the work which these groups are doing now against malaria and hookworm disease and in their efforts to improve environmental sanitation will be of great help as adjuncts to the direct efforts against tuberculosis. Public health expenditures in the Republic as a whole have increased in 10 years from \$0.08 Mex. to \$0.34 per capita for the Republic as a whole.

These are the means with which we expect to work in fighting this scourge in Mexico. Thus far, the actual clinical work has been hard, for the inadequate number of hospital beds has made it necessary to increase the turnover per bed to its maximum. Therefore, the 220 beds in the principal tuberculosis hospital have been used chiefly for surgical treatment, of which the volume is larger per bed than that in similar hospitals elsewhere. The dispensaries have been used for pneumothorax treatment of ambulant cases, and tuberculosis wards in general hospitals for the isolation of advanced cases in their terminal stages. This policy has emphasized the protection of the family by isolating the patient or by rendering his sputum negative, but of necessity it has omitted the provision of long periods of rest for many patients who might have benefited.

Because our campaign is in its early stages, and the public is not yet prepared to take full advantage of it, our clinicians have severe handicaps. Sixty-eight per cent of the patients when first reported show bilateral lesions; 50 per cent show cavities, and nearly 12 per cent present cavities in both lungs. Under such conditions extreme care is necessary in the selection of cases for surgery, and effective use of hospital beds by skillful technic and good judgment is essential.

The Federal Department of Health and the National Tuberculosis Committee feel that the period of develop-

ment of methods and of preliminary organization has been sufficiently extensive and, working together, they are now trying to develop to full capacity all of the resources which are available for their fight against this plague. The program for this year and those immediately following is to be devoted to the building of more hospitals and a rehabilitation farm in the Federal District, with an additional sanatorium for each of our coastal regions, at a total cost of about 5,000,000 pesos.

The program will increase the number of available beds by about 1,700, all of them devoted exclusively to the care of patients suffering from tuberculosis.

This is the situation of Mexico, so far as tuberculosis is concerned, and upon these plans we base our hopes for a better country and a healthier and happier people, your neighbor, your brother in ideals, in creeds and in thought, for a united and civilized American Continent.

THE BROAD VISIONED LAYMAN AS AN AID IN PLANNING

PERHAPS one of the shrewdest observers and interpreters of current events and affairs is Mr. Raymond Clapper, the columnist. Though occasionally he builds a fire under the near great or even the great, usually he writes in a restrained manner, free of the omniscience and cocksureness to which many columnists are addicted. In connection with the war effort in general, and in particular relation to production, he made this comment in the June second issue of the *New York World-Telegram*, "The expert again has been caught with his nose so deep down in the details and in traditional ways of operation that he missed the possibilities. Experts are indispensable. They are the fellows who get the job done. But sometimes it has to be started by the outsider who is just too ignorant to know about all of the difficulties. He hasn't sense enough to know there is a limit to what can be done, and, sure enough, time and again he turns out to have been nearer right than the men who knew all about it."

One cannot but agree that this observation is sound as regards plans for expansion of public health work after the war. Those who are in the thick of public health activities are rated experts and possibly, as such, are inclined to resent comments and suggestions from outsiders. But an inevitable cost for expertness is to be found in a lack of perspective, particularly as this perspective relates to broader issues. The expert is so occupied in the precise measuring or routine felling of individual trees that the direction of the prevailing wind and the position and significance of the woods in question are likely to go unobserved. In contrast, it is not an uncommon experience of health experts, in dealing with those whom they consider laymen, to obtain now and then some shrewd observation, apparently quite naïve in its inception, which disposes of a great writhing mass of questions for which the experts could find no common answer. In similar situations, too, one hears from time to time lay suggestions which, because of simplicity and boldness, we in public health would never have considered as a possible course of action. Now two things may be done in such circumstances. One might exhibit the tired tolerance of the professional for the amateur, and

indicate that fools may ask questions beyond the ability of the wise to answer; or due consideration may be given to each such suggestion which carries merit, regardless of its source and, most of all, regardless of its orthodoxy.

Not only do we recommend the latter course, but further we urge on public health experts the discussion of their post-war plans, large or small, with intelligent laymen who in their own fields have encountered problems generically the same. Obviously, the lawyer would not know much about viruses or vitamins, but in applied psychology he could give most professionals all the aces in the deck and beat them hands down. At the other end of the scale are those in the exact sciences, who generally know things rather than people. Behind them is such a rigid discipline of training, and in their daily work they must exhibit such an exactness of thought, that their basic-principle ideas may safely and productively carry over into fields outside their immediate specialties. Similar observations might be made on benefits to be derived from conference with the historian, the educator, the industrialist, the labor leader, the plain businessman; and if one in health work wants really to feel the public pulse and see his problems and plans as others see them, let him talk with the taxi driver, the tenant farmer, the man with the shovel, the butcher's boy.

We need these associations in our planning for the future. Naturally, from them would come many crack-pot suggestions. Sheer ignorance and stupidity would occasionally give rise to puerile observations, and prejudices would not infrequently color the advice that one got. Nevertheless there would be much that is worth while if one chose his consultants wisely, and the fresh viewpoints and unfettered suggestions thus obtained would stimulate the expert to strike out for far horizons. A good mind is worth exploring, regardless of whether that mind is in the skull of a banker, a businessman, or even a politician.

THE NEED FOR CONTINUING STUDY

NO inconsiderable part of the scholar's armamentarium is the knowledge of where to look for information, and the availability of texts, monographs, journals, reprints, etc., when wanted. For one whose work is in a university or a large health department with library facilities, this matter of getting information is made amazingly easy. Discussions with his associates, with visiting colleagues, an abundant supply of periodicals, shelves of rich source materials, current indices, and even bibliographic and abstract service make reception of current and past knowledge easier than remaining uninformed.

One who lives in such circumstances; therefore, likely to forget the plight of those laboring on the far frontier of public health work: the medical officers of health, the public health nurses, the engineers, and others on the staffs of rural health departments. Seldom do these people have the stimulating experience of visitors and, outside of their immediate staff associates, there are not locally any others in their respective professions who are engaged in public health work. Their reading material, with few exceptions, is limited to such books and professional journals as they might be able to pay for from their own slim salaries. Their departmental budgets for their programs with skin-tightness, and there is no slack for purchase of reference texts or periodicals. Even when at the end of the year there is some unlooked for balance in the contingent or miscellaneous fund, the

local agency lacks authority to spend it for such a luxurious purpose as books—or is too hard pressed by some other need even to consider an expenditure for this purpose.

We know too much of the rural budget and of state and local problems to visualize or advocate a library in each small health department. Yet we know, too, that continuing study and current reading is an acute need of those who work, unsung, in difficult circumstances. And we feel that the situation is worse than it need be. It is deficient not because of any opposition to it by those higher up, but rather because there has been a tendency to overlook it under the necessity of meeting demand services. In all fairness, too, it must be said that some state health departments are trying to overcome the situation through news letters, a central lending library, institutes, and regional conferences. These measures help, but after all they do not serve the same purpose as readily available books and regularly received journals. Would it be stretching too far the definitions of "equipment" or "supplies" or "upkeep" to consider books and journals as coming under one of these budgetary headings? In the end it is just as important, possibly even more important, to feed the minds of the staff as it is to get furniture for the office, provide coal for the furnace, or repaint the front door.

WHAT AND WHO IS AN EPIDEMIOLOGIST?

Comments on an editorial published in the April, 1942, issue of the JOURNAL:

From Ralph E. Wheeler, M.D., of Vanderbilt University Medical School, comes this comment:

"Like his prototype, the clinician, the epidemiologist (the 'Doctor' of actually or potentially sick *groups of human beings*) is an observer with many strings to his bow. First of all he is clinician enough to be able to identify ailments by making and evaluating observations in a wide variety of fields—history, physical and laboratory—as they apply to the individual. If he can't actually make these observations he at least knows enough about making them so that he can 'ride herd' upon those who do. Second, he is statistical analyst enough to use statistics where their use is indicated in the collective field: primarily to find groups maximally at risk. The rate, commonly used to express this risk, is not a bad shibboleth by which to test the genuine-

ness of one who calls himself an epidemiologist. If he quibbles mightily over the numerator and grabs up anything that offers for a denominator, he is really a clinician at heart. If he accepts anything that offers—be it only reported cases—for the numerator and bickers endlessly over the denominator he is probably a biostatistician. If he frets indefinitely over both numerator and denominator he is more likely to be an epidemiologist. It is not possible to say that individuals in this latter category *are* epidemiologists because clinical and statistical ability are but two of the necessary qualifications. With these two skills alone one can merely explore ways of transmission (or risk) of manifest illness in gross categories. Finer categories of susceptibility are available through the laboratory where confirmatory evidence on suspected modes of transmission and *sources* may

also be identified. Nor can the word 'laboratory' be construed too narrowly: bacteriology, chemistry, parasitology, and physics contribute their share.

"Beside having clinical, statistical and various laboratory facets the epidemiologist is a basic observer in other fields—at least trained and experienced—in sanitation and sociology. General

biology and geology as hobbies suddenly loom large as professional aptitudes at times.

"In the broad warfare on disease, the epidemiologist leads task forces against particular objectives. He adapts his forces to the nature of the objective. To get the most out of each weapon at his disposal, he should have had both training and experience in its use."

M. J. Rosenau, M.D., of the School of Public Health, University of North Carolina, has this to say:

"An epidemiologist is a disease detective. This definition would not suit an historical epidemiologist, and on the other hand a statistical epidemiologist would have difficulty in fitting a curve to any definition supplied by an experi-

mental epidemiologist. An applied epidemiologist who looks practical realities in the face would consider any definition of the other kinds of epidemiologists as a description rather than as a definition. Anyhow, a shoelather epidemiologist would have no quarrel with Dr. Watson if he called him a disease detective."

C.-E. A. Winslow, Dr.P.H., Professor of Public Health, Yale University School of Medicine, contributes the following comment:

"The question raised by your editorial 'What and Who Is an Epidemiologist?' can, I think, only be answered in rather broad terms. I think anyone may claim this title who is either advancing or applying knowledge in relation to the causation and control of herd diseases (not necessarily limited to those of microbic origin). There are at least three major lines along which knowledge of this kind may be developed; statistical epidemiology, clinical case studies (as developed by Opie and Paul), and experimental epidemiology—just as in chemistry we

may have physical chemists and physiological chemists. Except in the field of experimental epidemiology we must include both those who contribute to basic scientific knowledge, and those who apply such knowledge in the field of health department practice. A scholar who analyzes the history of epidemiological thinking certainly deserves a place in the scheme, and so does the health official working in the field of communicable disease control—at least if his applications are made on the basis of the best available fundamental knowledge. In the area of either theory or practice he should have special training, but we cannot exclude those who have obtained this training by the road of arduous experience."

BOOKS AND REPORTS

Four Treatises of Theophrastus von Hohenheim Called Paracelsus—Translated from the original German, with introductory Essays by C. Lilian Temkin, George Rosen, Gregory Zilboorg, Henry E. Sigerist—Edited, with a preface, by Henry E. Sigerist. Baltimore: Johns Hopkins Press, 1941. 256 pp. Price, \$3.00.

One of the most influential nonconformists in science was the Swiss physician Paracelsus (1493–1541). His bitter opposition to the then current orthodox medical canon had little influence at his time. His ideas, however, powerfully assisted in 16th and 17th century application of chemistry to medical practice. His semi-mystical speculation made him a hero to many 19th century Romantics.

Dr. Temkin's translation of the *Sieben Defensionen* offers an excellent personal picture of Paracelsus and his ideas. Dr. George Rosen's translation of *Von der Bergsucht und andern Bergkrankheiten drei Bücher* is a significant interpretation of the first important treatise on occupational diseases. From his personal experiences, Paracelsus had direct acquaintance with miners' diseases and his observations constitute the origin of industrial medicine and hygiene. Paracelsus realized the importance of what we would now term "public health measures." Unfortunately he seemed to have no practical suggestions for preventing the conditions he described so well.

Another pioneering work of Paracelsus in his *Von den Krankheiten, so die Vernunft berauben*, translated here by the psychiatry historian, Dr. Gregory Zilboorg. This deals with mental disorders and in many ways seems to anticipate modern views. Contrary as usual to the then customary belief,

Paracelsus approached mental disorder in a rationalistic manner, relatively free from demonism, and based on his own experiences. He appreciated the significance of unconscious and sexual factors in mental disorder, and otherwise showed many manifestations of modern psychiatry trends.

Dr. Sigerist translates the poetic *Liber de nymphis, sylphis, pygmaeis et salamandris et de cacteris spiritibus*. This is one of the most artistic, and philosophical of the writings of Paracelsus, but also one of the most difficult to appraise.

For the practical public health worker of today, the treatises *On the Miners' Sickness* and *On Diseases that Deprive Man of His Reason* are the contributions of Paracelsus most likely to hold interest. Dr. Sigerist and his associates deserve appreciative congratulations on issuing this important historical study at this time. CHAUNCEY D. LEAKE

Doctors Anonymous—*The Story of Laboratory Medicine*—By William McKee German, M.D. New York: Duell, Sloan and Pearce, 1941. 300 pp. Price, \$2.75.

In this book the author makes a convincing plea for the recognition of the pathologist, who, he says, is "the unknown man of medicine," yet much of the diagnosis of disease and a great deal of the treatment are based on his discoveries and findings. He has no desire to exalt the pathologist unduly since no one specialty in medicine is greater than the others, all parts functioning together for a real scientific life. A history of the past 50 years, which covers pretty well the time since modern pathology had its birth, is particularly good reading, informative, and dramatic.

Every physician knows the value of

the post-mortem and is aware of the many superstitions which existed and blunders made before study of disease in the cadaver was allowable. Every honest physician knows of blunders in diagnosis which could have been avoided by bacteriological and pathological tests.

In surgery the frozen section done on the spot often determines the extent and character of the operation. The many facts brought forward in the numerous case histories cited are convincing arguments for the greater recognition of the part played by the pathologist in the everyday practice of medicine. This was recognized by the American Medical Association and the American Society of Clinical Pathologists; so in 1936 the American Board of Pathology was incorporated with authority to issue certificates of proficiency in the special field of pathology to those meeting the required standards.

In spite of what we know, a recent survey, 1939, shows that there are only 4,673 departments of pathology in the 6,166 approved hospitals, and these were directed by only 3,601 medical graduates, the conclusion being that only about one-fifth of these men have qualifications equal to those required for certification by the American Board of Pathology.

The pathologist is important from other standpoints. Too many cases of murder—poisoning, for example—have gotten by through lack of proper examination by a trained man—"Crime without punishment." The author takes a well deserved slap at what he calls "coroner's thrombosis," a diagnosis made from superficial examination.

The book is also of necessity more or less a study of human nature as discussed under "Fads, Fashions and Disease." A slap is also made at medical ethics which too often interfere with the correction of blunders. The author asks "ethics or diagnostics?"

Though the book is evidently intended

for the public, the doctor is not neglected. It is pleasantly written and, with the exception of one chapter, can be understood by the public. Modern medicine is likened to a tree—the trunk and branches suggest clinical medicine; the roots, invisible below the soil, are the science of the laboratory. They all go, however, to the formation of the same living, growing thing.

The book can be commended without hesitation. The printing and make-up are excellent. The author has fallen in with the fad of having an introduction by a popular writer. Once again let us impress on the writing public that "Good wine needs no bush."

MAZÛCK P. RAVENEL

Industrial Waste Treatment Practice—By E. F. Eldridge. New York: McGraw-Hill, 1942. 401 pp. Price, \$5.00.

This book is based on industrial waste data collected by the author as research associate of the Engineering Experiment Station at Michigan State College. Some of the material was originally published in 1938 in *Bulletin* 82 of the Station. The book greatly enlarges and revises the data in this bulletin and brings between two covers the most complete and authoritative discussion of industrial wastes published. For some years there has been need for just such a volume as this—one that will serve as a guide to engineers and plant operators faced with industrial waste problems.

The book devotes a chapter to each industry in the United States contributing troublesome industrial wastes. These include wastes from beet sugar, milk, canneries, tanning processes, pulp and paper mills, textile mills, meat and slaughter houses, laundries, metal industries, gas and coke manufacturing, fermentation wastes and oil. In each chapter the manufacturing processes are described, the composition of the waste

materials given, and treatment processes and sludge disposal methods discussed. That the author has done well with his subject is well exemplified in his handling of the complicated and varied processes in textile manufacturing.

The value of the book is enhanced by chapters on the industrial waste problem, general stream pollution theory, the characteristics of industrial wastes, standard methods, structures and equipment employed in general sewage treatment practice, the laboratory analysis of industrial wastes, and a chapter on the treatment of domestic sewage when combined with industrial wastes. This last chapter is one of the most useful in the book and might profitably be enlarged in the next edition.

Analytical procedures for biochemical oxygen demand, suspended solids, acids and iron in pickling liquors, chlorine demand, cyanide, phenol, oil and grease as found in industrial wastes are included in a separate chapter. Emphasis is placed on determinations of biochemical oxygen demand and suspended solids as being of the most significance in indicating the strength of industrial wastes. The need of diluting many industrial wastes before determining the suspended solids by the Gooch crucible method is mentioned, and the steps to be followed are given. It would seem that the substitution of the Buchner funnel for the Gooch crucible might be an alternative.

The explanation of E. B. Mallory's activated sludge theory in the chapter on methods of sewage treatment is the clearest published and it will surprise the reader to find it in such detail in a book on industrial wastes.

The author quotes J. K. Hoskins as concluding that the organic pollution contributed by industry is about equal to that contributed by the entire population. Eventually industry will be required to go as far with waste treatment as has been expected of municipalities

in the treatment of sewage. The book in outlining the methods of industrial waste treatment now available is a valuable contribution to the sanitary engineering field.

LEROY W. VAN KLEECK

The Golden Jubilee of the Association of Military Surgeons of the United States—A History of Its First Half Century, 1891–1941—By Edgar Erskine Hume, Colonel, Medical Corps, United States Army. Washington: Association of Military Surgeons, 1941. 371 pp. Price, \$2.00.

Under the leadership of Dr. Nicholas Senn, a brilliant surgeon of Chicago and a prominent Surgeon in the National Guard, the Association of Military Surgeons of the United States was founded in Chicago during September, 1891. Those participating in the founding were National Guard Surgeons from several states. In this volume the author presents an interesting history of the association.

The Association of Military Surgeons of the United States has played an important part in developing and maintaining interest in medical military preparedness among the medical profession in this country during the past half-century. This is a worth while contribution for military medicine is a distinct specialty. Physicians and dentists, however thoroughly grounded in their professional work, must receive special training in order to fit them for service with the military and naval forces.

This history, dealing with the first 50 years of the work of the association, presents a complete, chronological account of the founding, the annual meetings, and the other events of importance in the affairs of the organization. Photographic cuts of all the presidents, editors, as well as facsimiles of documents and title pages of historical interest are included. The official journal of the association has been published

under one title or another since the founding of the association in 1891. The present name, "The Military Surgeon," has been used since 1901.

Colonel Edgar Erskine Hume, a distinguished officer of the Medical Corps of the Regular Army, the author of this history, is unusually well qualified to serve as a historian for the association. He has been a member of the organization for some 25 years. During about half of that time he has held office or served on the Executive Council. He has attended 20 of the 47 annual meetings, and has been personally acquainted with a majority of the men who have held office in the association. Colonel Hume has also represented the association at several international meetings of military surgeons held abroad and in the United States.

This is a valuable handbook where may be found in readable and compact form the essential facts relating to the Association of Military Surgeons.

R. C. WILLIAMS

Fatigue of Workers, Its Relation to Industrial Production — By the Committee on Work in Industry of the National Research Council. New York: Reinhold, 1941. 165 pp. Price, \$2.50.

This book is a report of the hearings of the above committee summarized and presented in an interesting manner by George C. Homans. The title of the report is misleading since it does not deal with fatigue, as usually implied by this term, but with the psychological and sociological factors which control the output of industrial employees and their attitude to work and management.

The first section, which is quite unrelated to the remainder of the book, presents briefly the experimental studies of Dill and McFarlane on the effects of heat and high altitude. In the next section, clinical psychoneurotic conditions which may result from industrial

maladjustments are illustrated in three cases studied by Dr. Canby Robinson.

The greater part of the report is devoted to studies, made by the Western Electric Company, of a selected group of employees over a period of years. The output of the workers was shown to be far less affected by the physical environment, hours of work, etc., than by psychological factors and the social conditions of work. The studies emphasized the need of workers to self-expression which resulted in the formation of informal organizations by the employees. These controlled their output, behavior, etc. The personal interview and other methods used by the Western Electric Company to produce a closer association between management and employees are discussed.

Labor's viewpoint on self-expression and labor unions is represented by Harold Ruttenberg. Problems involved in setting output standards and time allowances for tasks are discussed by Dr. Jacob Blair. The final section is a review of Chester Barnard's book *The Functions of the Executive*.

This report is very timely since it presents scientifically the fundamental problems which control industrial relations and output. ANNA M. BAETJER

Stedman's Shorter Medical Dictionary — By Thomas L. Stedman. Chicago: American Publishers Association, 1942. 277 pp. Price, \$2.50.

A "completely revised and enlarged" edition of this widely circulated dictionary should be as useful for most purposes as the unabridged edition. However, it is regrettable that the information on the acute communicable diseases apparently has not been brought up to date since the death of Dr. Stedman and should certainly be brought into conformity with the official report of the American Public Health Association.

REGINALD M. ATWATER

Heating, Ventilating, Air Conditioning Guide (20th ed.)—*New York: American Society of Heating and Ventilating Engineers*, 1942. 1,136 pp. Price, \$5.00.

This volume presents, in accordance with its established policy, the latest authoritative information of value to heating, ventilating, and air conditioning engineers. Many changes have been made in the text material; new material where such was available has been added; and a new chapter on fundamentals of heat transfer has been included. As before, the volume is divided into several sections dealing, in general, with types of heating, cooling, and air conditioning systems and their control, as well as the fundamental thermodynamic principles and their application to this field. Numerous examples are given illustrating methods of computation, and, as in previous editions, there is included a Manufacturers' Catalog Data Section describing available equipment. C. P. STRAUB

Proceedings and Papers of the Twelfth Annual Conference of the California Mosquito Control Association—*Notes and Transcription by Margaret A. Prefontaine, Edited by Harold Farnsworth Gray. Richard F. Peters, Secretary-Treasurer, 3093 Life Sciences Building, Berkeley, California*, 1941. 143 pp. (with notes on the identification of California mosquitoes by William C. Reeves). Price, \$1.00.

The proceedings of the Conference were divided, in effect, into four symposia; namely, encephalitis in California, mosquito control in relation to national defense, new information on the entomology of mosquitoes, and mosquito control operations in California. Only the symposium on encephalitis lends itself to review, and its three interesting papers should be read in the original.

Serological surveys indicate the es-

tablishment and coexistence of western equine and St. Louis virus in rural, agricultural sections of the central valley of California where the encephalitides they cause are endemic, as well as in supposedly non-endemic (coastal) areas and Yakima Valley in Washington. Evidently the St. Louis virus has been present for some time and not recently imported as supposed formerly. Antibodies for the western type virus predominate in humans, horses, domestic fowls, and wild rodents, but antibodies for both types are found frequently in the same animal, particularly in horses.

There is a definite seasonal prevalence of encephalitis in horses and man, with the peak of incidence being reached in late summer and the peak for horses usually preceding that for man. Evidence is presented that transmission is probably from domestic animals to a biting insect to man. While ticks (*Dermacentor andersoni*) and the cone-nosed bug (*Triatoma sanguisuga*) may be natural vectors of western virus, it is probable that mosquitoes are the principal vectors. Mosquitoes of the genus *Aedes* can transmit western equine virus and *Culex tarsalis* have been found infected naturally with both western and St. Louis viruses. Epidemiological evidence apparently incriminates the latter mosquito. There may be more than one mosquito vector, and possibly special vectors from animal to man and from animal to animal. However, the transfer of viruses in nasal secretions has not yet been ruled out.

ROBERT BRIGGS WATSON

Food and Drug Regulations—*By Stephen Wilson. Washington: American Council on Public Affairs (2153 Florida Ave.)*, 1942. 177 pp. Price, \$3.25 (cloth); \$2.50 (paper).

From the opening statement of the introduction by Professor W. H. Hamilton to the last sentence of the final

chapter, this book is replete with important facts, incidents, and excerpts of debates leading up to and through the passing of both Federal Food and Drug Acts of 1906 and 1938. One chapter is devoted to the history of food and drug legislation from the days of the Athenians and Romans to the passage of the Pure Food and Drug Act of 1906. Then follow three chapters of the history of this latter Act, its difficulty in administration, and its weaknesses. The campaign for a new federal food, drug and cosmetic law with its ultimate passage in 1938 and its causes and consequences are discussed in the last three chapters.

This book should be obtained by every food and drug control official because it is a complete story of food and drug legislation of the federal government. There are practically no errors in printing, the type is clear and easily readable, and there are many references.

No mention however, is made of state and local food and drug legislation. The title of the book, therefore, could very well be, "Federal Food and Drug Regulations." FERDINAND A. KORFF

Superior Children through Modern Nutrition—*By I. Newton Kugel-mass, M.D. New York: Dutton, 1942. 332 pp. Price, \$3.50.*

In this book intended for laymen, the author strives for erudition. For example, among the vitamins he lists vitamins I, J, L, M, P, T, U, and W, attributing to some of them an importance in human nutrition not yet proved.

His data vary each time he quotes figures. The vitamin A content of a quart of milk is given on page 29 as 150 units, whereas on page 34 a pint of milk is stated to yield 1,000 units; in the table on page 37 one "serving" of milk contains 720 units, while in the table on page 317 one serving con-

tains 570 units. The book contains many similarly careless statements.

Such pseudoscientific pronouncements as the following are unacceptable. "Does nursing sap a mother's strength? . . . Since breast milk is derived from nutrients in the mother's blood there is no depletion of strength, but only extra utilization of her daily diet" (page 122). "When a solid food is offered for the first time and the infant refuses or vomits it, the probability is that his organism is allergic to this food and unable to utilize it properly" (page 222). "Without the right start during the formative months of fetal life, a lifetime of nutritional devotion to the cause of good teeth will not correct this maternal mistake" (page 95). "In fact the child on an ordinary diet only develops his optimal quota of brain well after the sixth year. If breast fed his intelligence quotient is apt to be higher than if artificially fed because breast milk contains 100 per cent more galactose than cow's milk" (page 89).

Undue stress is placed on the prevention of constipation. Among the many references to this condition is found the statement (page 227), "Constipation in the infant is inevitable if little importance has been attached to emptying the bowel or insufficient time devoted to this act. Bowel control may be instituted by proper training during the first months of life." The giving of prune juice is advised as early as two weeks of age for the prevention of constipation; the use of orange juice for its vitamin C content is recommended in the first week of life on page 46, whereas the feeding schedule on page 182 advocates it at one month of age.

The defects of this book tend to outweigh the usefulness of other portions. Because the uninformed mother cannot distinguish between fact and fiction in the field of childhood nutrition, the book is not to be recommended.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Federal Venereal Disease Program in Action—In this series is told what the War and Navy Departments and the U. S. Public Health Service and the Social Protection Section of the Defense Health and Welfare Services are doing about controlling syphilis and gonorrhea.

ANON. (Four papers) Fit to Fight—and Fit for Life, "Best Traditions of the Service . . .," "Health Is the States' Foundation . . .," Safeguards Plus Salvage. *J. Social Hyg.* 28, 1:3 (Jan.), 1942.

Venereal Disease among Industrial Workers—Four and a half per cent of the first million draft selectees had syphilis. One of every 42 in the general population has the disease now. How great is the loss of time and efficiency due to the disease we shall never know, but it is evident that public health administrators, employers, and employees ought to be on the job preventing that loss. "In time of peace industrial hygiene is a tool. In time of war, we must make it a weapon."

ANON. Health Builds Manpower. (An editorial summarizing seven papers on V. D. in industry.) *J. Social Hyg.* 28, 2:108 (Feb.), 1942.

Vitamins Important? So Are Emotions—Six articles giving a bird's eye view of nutrition with a mental health slant, prepared primarily for classroom teachers, but of equal value for health educators, full- or part-time.

BINGLER, C. A Word to Teachers About Eating Habits (and five related papers). *Understanding the Child* 9, 1:3 (Apr.), 1942.

Some Light upon the Great Darkness—We may consider the possibility now of preventing several forms

of cancer in man by attacking the disease at its origin instead of remaining on the defensive until the disease has opened the attack. This is the hopeful conclusion of an able discussion of the question, Why does a patient get cancer?

CRAMER, W. The Origin of Cancer. *J.A.M.A.* 119, 4:309 (May 23), 1942.

About Leeuwenhoek, et al.—In this discourse covering four and a half centuries of public health and the place of the laboratory at the end of that time, there is much quotable material. One nugget: "We do not want too many epidemiologists whose chief functions . . . are the compiling of convincing itineraries to cover where they went and what they did on their latest peregrination, . . ."

DOLMAN, C. E. The Changing Place of the Laboratory in Public Health. *Canad. Pub. Health J.* 33, 5:185 (May), 1942.

Today's Lepers Are Lucky—As the day may come when you may have need to tell someone this reassuring story, make a note that there is available an excellent description of the modern leprosarium at Carville. Each year from 40 to 60 new cases are discovered and admitted.

FAGET, G. H. The Story of the National Leprosarium (U. S. Marine Hospital) Carville, Louisiana. *Pub. Health Rep.* 57, 18:641 (May 1), 1942.

Laboratory Note—Chicks are recommended as a substitute for rabbits or guinea pigs in testing virulence of the diphtheria bacillus.

FROBISHER, M., JR., et al. The Use of Chicks in Testing the Virulence of *Corynebacterium diphtheriae*. *Am. J. Hyg.* 35, 3:381 (May), 1942.

For Radium Dial Painters—Increased demand for luminous dials and time pieces has put radium painting on a broader scale. With properly vented work tables and established safe shop practices, it can be done without jeopardy to health and life. This article tells how.

HEMEON, W. C. L., and EVANS, R. D. Ventilation Requirements for Radium Dial Painting. *J. Indust. Hyg. & Toxicol.* 24, 5:116 (May), 1942.

Shall We Save Children's Teeth?—After age six, so dental surveys have shown, permanent teeth are attacked at a constant rate of three-fourths of a tooth per child per year. Thirty million children would accumulate 22,500,000 carious teeth each year, but they could be cared for with only 18 per cent of the American dentists' available time and the more important prophylactic work need not take a disproportionate share of this time either. Many public health officials assume that the job to be done is too great, and the cost prohibitive, so they do nothing. This paper persuasively proposes that as something can be done, something should be done to tackle the job realistically.

KNUTSON, J. W. Appraising the Dental Health Program. *J. Am. Dental Assoc.* 29, 4:543 (Apr.), 1942.

Polio Epidemic Studied—Epidemiologic evidence indicates that, during one poliomyelitis outbreak, the infection was spread mainly not by contact but by certain vectors unknown. Animals, houseflies, blowflies, mosquitoes, and fleas are considered as possible vectors. On the whole, the picture indicated spread of infection by place rather than person.

LUMSDEN, L. L. An Epidemiological Study of Poliomyelitis in Mississippi in 1941. *Pub. Health Rep.* 57, 20:729 (May 15), 1942.

Contacts, Not Fomites, Spread Scabies—Three British papers on the

transmission, the treatment and the control of scabies will interest those of us who may be pestered with the control of this condition. Evidently in England there has been an increase in the endemic infestation. Recognition of early cases and control of carriers, rather than fomites, are the great needs.

MELLANBY, K., *et al.* Transmission and Prevention of Scabies (and two related papers). *Public Health* 40, 8:150 (May), 1942.

Rejectees with Syphilis and Gonorrhea—In one state, public health nurses are assigned to the army induction stations where all selectees are examined. A quick blood test and a microscopic examination inform the authorities in a few hours which of the selectees are venereally infected. Before each of these leaves the station he is interviewed by the nurse, plans are made for his treatment, and information about the source of infection is obtained. Would that every state did as much!

MOORE, H. B., and DILL, E. R. Venereal Disease Program for Rejectees. *Pub. Health Nurs.* 34, 5:266 (May), 1942.

Public Health in the War—Today health agencies face their supreme test, that of adapting themselves to broader purposes than that for which they were organized, concludes the Surgeon General. What he has to say to the Conference of State and Territorial Health Officers suggests that some of us are not making too successful a beginning on meeting that supreme test. If you haven't already done so, read this paper, and the proceedings of the conference which follow it.

PARRAN, T. Opening Remarks to the Fortieth Annual Conference of the United States Public Health Service with the Conference of State and Territorial Health Officers. *Pub. Health Rep.* 57, 19:691 (May 8), 1942.

Lily Painting Department—Here is proof that the risk of tuberculosis

is very great for colored associates of sputum positive cases—if you should be in need of this proof.

PUFFER, R. R., *et al.* Tuberculosis Studies in Tennessee. *Am. J. Hyg.* 35, 3:367 (May), 1942.

First Aid Treatment for Gas—

What to do—and emphatically what not to do—in giving first aid to victims of lung irritants, mustard and tear gases, nerve and blood poisons, carbon monoxide, and phosphorus. Certainly every health worker should be ready with this information, and this is an excellent article.

WAITT, A. H. War Gas Cases. *Am. J. Nurs.* 42, 5:489 (May), 1942.

Proprietary Vitamin Products—

Although the needed intake of the vitamin B complex may be obtained from a satisfactory diet of ordinarily ob-

tainable foods, many American diets are low in this essential. A survey of a number of vitamin B preparations indicates that many of them are wholly inadequate sources. The economic waste involved in producing and using these questionable dietary supplements must be great.

WILLIAMS, R. J. The Approximate Vitamin Requirements of Human Beings. *J.A.M.A.* 119, 1:1 (May 2), 1942.

More About Vitamins—If you are one who likes occasionally to take his intellectual nose from the grindstone of severely “practical” information anent his job, then you may enjoy these two entertaining though scholarly papers on what we know, what we don’t know, what we hope to know about vitamins.

WILLIAMS, R. R., and WILLIAMS, R. G. Vitamins in the Future. *Science* 95, 2466:335 (Apr. 3), 1942.

The auditorium will seat up to 11,500 persons.*

The Seventy-first Annual Meeting in St. Louis

YOU who have been to St. Louis before won't recognize her face or figure when you rail, bus, motor, or plane into town October 25 or 26 for the annual convention of the American Public Health Association.

For one thing, that old dirty face is gone. The city's smoke elimination program, which has been given nationwide publicity, has been increasingly effective since its inauguration two years ago. Her citizens are literally breathing freer—and the old lady, herself, is becoming more vain each day as she adopts the use of cosmetics and soap and water—painting and sand-blasting—for a fresh appearance.

St. Louis's old figure also is becoming more streamlined. Do you remember the sprawling river front? The old buildings have been torn down and a beautiful park—the Jefferson National Expansion Memorial—has been planned. Government model housing projects also are under way and some predict that St. Louis, long known as the city of beautiful homes, soon will be known as the "model city."

THE GATEWAY TO THE WEST

The story of St. Louis is one of the most colorful pages in American history. Just 401 years ago, in 1541, the Spanish adventurer, Hernando De Soto, and a handful of goldseekers discovered the Mississippi River. Two hundred and twenty-three years later, in 1764, Pierre Laclede and Auguste Chouteau founded its greatest city—St. Louis.

From fur trading outpost to industrial center—from French and Spanish rule to American Democracy—from 30 hardy pioneers to 1,500,000—through fires and floods, Indian raids and wars, financial panics and depressions, St. Louis has become ever more virile and far sighted. It is one of the nation's most modern cities now. But the colorful landmarks of the sturdy frontier town still stand.

FRONTIER LANDMARKS

Outstanding is the old Courthouse at Broadway and Chestnut Street. It was there that the famous Dred Scott case was tried—a case on the legality of slavery which changed the course of

The Meeting of the Waters, by Carl Milles—on Aloe Plaza across the street from Union Station.

American history. Slaves once were sold at the stone auction block at the east door. It was the starting point of the Daniel Boone trial. It was there that Henry Clay attended court and sold real estate.

Even closer to the river is St. Louis's oldest building—the Old Rock House—a famed rock structure once used as a depot for supplies and furs for traders. Not far from it is the nationally known Old Cathedral on the river front, site of the first Mass in 1764. The origin of St. Louis is epitomized on the portico with three inscriptions—French, Latin, and English. To sweeten the bell's tone, 200 Spanish dollars were cast with other metal. Not far from the heart of the city stands Grant's Log Cabin, occupied by the famous Civil War general when he was a St. Louis resident.

Among other points of interest to the history-minded visitor are the site of the old National Hotel, which once housed Daniel Webster, Abraham Lin-

coln, and others; the Eugene Field House, where St. Louis's famous poet was born and lived most of his life, and the Dent-Grant House, where General Grant married Julia Dent.

For a living story of what made Missouri great, the visitor has only to see the rare historic collection at Jefferson Memorial, located at the entrance to the grounds of the 1904 Louisiana Purchase Exposition, in Forest Park. Rare books, precious manuscripts, Indian relics, and objects of pioneer days are housed in the Memorial.

Upon these solid foundations of law and freedom, religion and art, trade and industry—typified in these old landmarks—St. Louis was built.

MODERN ST. LOUIS

But what of modern St. Louis? St. Louisans like to boast that one never is at a loss for things to see or do.

If you arrive by train, the first thing that strikes your view is the beautiful

statue by the famed Swedish sculptor, Carl Milles—"The Meeting of the Waters"—directly across from Union Station. The fountain symbolizes the junction of the Mississippi and Missouri Rivers, while the huge railway station, modeled after the gates of Carcassone, is the actual junction of rail lines, 19 of them from all sections of the country.

Going to your hotel, which is but a short ride from the station, you cannot help noticing the beautiful downtown buildings—the magnificent new Civil Courts Building, the United States Customs and Courthouse, the old City Hall and Municipal Courts Building.

"OLE MAN RIVER"

Perhaps you'd like to see a little more of the city before your convention opens? Of course, you'll want to go down to the old river front to watch the tugs slowly pushing barges loaded with vital war materials down the river. Now and then, a colorful, old river packet of the type described by Mark Twain moves slowly upstream, in sharp contrast to the sleek coast guard cutters

and small motor launches. Near impressive Eads Bridge, the world's first steel-truss bridge, built in 1874 at a cost of nearly \$10,000,000, you'll see the world's largest inland excursion boat—the million dollar, streamlined, and air-conditioned S. S. Admiral.

Perhaps you'll have time for the short ride to one of the country's largest parks. Out at Forest Park, there is something for every taste. Do you like sports? In the park, as in other spots throughout the city, are facilities for golf, baseball, fly-casting, tennis, picnicking.

CIRCUS DAY

Do you get a kick out of a circus? Well, St. Louis has one every day at the Zoo, reputed to be one of the most complete exhibits of animal life in the world. And no trip to St. Louis is complete without a jaunt or two to Forest Park to watch the chimpanzees, elephants, and cats strut their stuff in twice or three times daily shows. Two rare pandas, Happy and Pao Pei, tumble around constantly for the visitors' amusement.

Flowers bloom all year in St. Louis. Here is a scene at the famous Shaw's Garden.

"Ole Man River—she just keeps rollin' along." Visitors to St. Louis are especially anxious to see the Mississippi, the world's most colorful waterway.

Each year, millions of visitors watch Jimmy, the trained chimp, and his "gang" turn backward somersaults, ride bikes, smoke cigarettes, play in an orchestra, and put trained ponies and dogs through their paces. Others like to watch the feeding of barking sea lions, the clumsy wanderings of the bears, or the awe-inspiring force-feeding of the giant boa-constrictor.

The zoo is huge. It covers more than 77 acres and houses thousands of mammals, birds, fish, and reptiles. Its most outstanding feature is its unusual back-to-nature barless "cages." Every effort has been made to simulate the natural surroundings of the particular animals' habitats.

Are you interested in art? The St. Louis Art Museum officials have dem-

onstrated that one does not have to be in the lorgnette class to enjoy fine painting and sculpture. The policy of appealing to the great class of people who have had no special training in art was foremost in the minds of the museum's founders—and a policy which has been followed throughout its history since it was originated in free evening drawing classes sponsored in 1874 by Washington University to the present day.

The museum is housed in a huge million dollar building of Bedford stone on "Art Hill," in the central western section of Forest Park. An impressive statue of bronze—"St. Louis, the Crusader"—stands before the building. Among the most interesting exhibits at the museum are the period rooms, which include medieval displays, a Gothic

Court, early French rooms, a Hispano-Moorish Court, and five American and five European period rooms. There are excellent collections of Oriental rugs and Chinese ceramics.

FLOWERS IN OCTOBER

Do you like puttering around in the garden? Then, don't miss seeing the floral exhibits at the Jewel Box in the park. The St. Louis Park Department offers a changing display of plants from 500,000 floral specimens grown in the park greenhouse. The Jewel Box is uniquely designed in the modern manner in steel and glass. Incidentally, you also will want to see the Missouri Botanical Garden, better known as Shaw's Garden, down in South St. Louis. It is rated with the Kew Gardens of London as the greatest in the world from the standpoint of completeness of collections. Its 75 acres are especially noted for rare lily hybrids and orchids.

Yes . . . and there are many more interesting things to be seen in St. Louis, too—just ask any of the friendly people you run into on the street. St. Louisans

brag that their amusement spots—night clubs, theaters, stage plays—can't be beat. But, they are even more proud of their churches, schools, hospitals, and homes. They like sports teams and their symphony. . . .

ALL-AMERICAN CITY

The St. Louisan is an all-American. For to St. Louis have come residents of every other section of the country. He has the strength of the North, the friendliness of the South, the experience, knowledge, and tradition of the East, the far-sightedness of the West.

Make arrangements now to attend our annual convention in St. Louis, October 26 to 30. Clear your desk; jot it down on your memo pad. For one of the most helpful and interesting conventions in the history of the American Public Health Association, we'll see you in St. Louis!

This is the physical setting for the Association's 71st Annual Meeting. In the August JOURNAL we shall tell you what St. Louis has to show you as a public health worker.

CLOSING DATE FOR SUBMITTING FELLOWSHIP APPLICATIONS

MEMBERS who may be interested in applying for Fellowship in the A.P.H.A. are hereby advised that Fellowship applications should be received not later than August 1, to insure consideration at the 71st Annual Meeting.

WANTED: The following issues of the *American Journal of Public Health*—July and August, 1941; and January, 1942. The Association will be glad to pay postage.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Franklin V. Boyd, M.D., St. Landry Parish Health Unit, Opelousas, La., Director
 Edward W. Colby, M.D., 173 Water St., Exeter, N. H., Health Officer, Eastern Health Dist., State Board of Health
 James M. Coram, M.D., Health Dept., Beckley, W. Va., Raleigh County Health Officer
 Thomas D. Fitzgerald, M.D., M.S.P.H., University Health Service, Ann Arbor, Mich., Physician
 Richard P. Good, M.D., 308 Armstrong Landon Bldg., Kokomo, Ind., Vice-President, City Board of Health
 Thomas L. Harvey, M.D., 805 Lincoln Ave., Newport, Tenn., Director, District Health Dept.
 Eugene L. Kidd, M.D., Chehalis, Wash., Lewis County, Health Officer
 Helen P. Lanting, M.D., M.S.P.H., Gladwin, Mich., Director, Tri-County Health Dept.
 Clarence R. Lindgren, M.D., Lane County Court House, Eugene, Ore., Lane Co. Health Officer
 Alexander S. Mack, M.D., 320 Locust St., Oak Harbor, Ohio, Ottawa County Health Commissioner
 Charles W. Reid, M.D., Madison-Tensas Bi-Parish Health Unit, Tallulah, La., Director
 Reuben F. Reider, M.D., D.P.H., 307 S. Wright St., Champaign, Ill., Director, Champaign-Urbana Public Health Dist.
 Oscar Rogol, M.D., C.M., 135 Main St., Seymour, Conn., Health Officer, Town of Oxford
 William T. Veal, M.D., 99 Water St., Stonington, Conn., Health Officer
 Michael A. Viggiano, M.D., New Martinsville, W. Va., Wetzel County Health Officer
 J. Margaret Warner, City Hall, Burlington, N. J., Sanitary Inspector, City Board of Health
 Winfield E. Wight, M.D., 24 Goodwin Court, Thomaston, Conn., Health Officer
 Angelo M. Williams, M.D., M.P.H., 56 Highland St., Burgettstown, Pa., Dist. Medical Director, State Dept. of Health

Laboratory Section

James H. Baker, M.A., 110 W. 18th St.,

New York, N. Y., Chemist, Gar-Baker Laboratories, Inc.

Ernest H. Blaustein, A.B., 36 Quincy St., Roxbury, Mass., Student, Massachusetts Institute of Technology

Hernando Groot, M.D., 55 Shattuck St., Boston, Mass., Student, Harvard School of Public Health

Roberto Nevarez, M.D., 59 Hancock St., Boston, Mass., Student, Harvard School of Public Health

Ross A. Snider, M.S., E. Third & Kilgour Sts., Cincinnati, Ohio, Asst. Chemist, U. S. Public Health Service

Gustave B. Ulvin, Ph.D., 130 W. Garfield Blvd., Chicago, Ill., Chief Chemist and Bacteriologist, Sidney Wanzer & Sons

Bernard Witlin, Sc.D., P. O. Box 3378, Honolulu, T. H., Bacteriologist, Territorial Board of Health

Engineering Section

Norman G. Ambrosini, B.S., 105 South F. St., Aberdeen, Wash., County Sanitarian, Grays Harbor Public Health Dept.

Ernest C. Anderson, M.S., Wichita Health Unit, Wichita Falls, Tex., Asst. Public Health Engineer, U. S. Public Health Service

Holbrook A. Bourne, M.P.H., 550 Main St., Hartford, Conn., Acting Director, Bureau of Food and Sanitation, City Board of Health

Edward B. Carroll, A.B., 709 Ridgeway Ave., Morgantown, W. Va., Senior Sanitarian, Public Health Training Center

Lieut. Henry M. Chick, Station Hospital, Fort Jackson, S. C., Sanitary Corps, U. S. Army

Ralph S. Lake, 427 E. State St., Rockford, Ill., Chief Plumbing Inspector, City of Rockford

Lieut. Irvin M. Lefton, M.S.P.H., 4028 North 16th St., Milwaukee, Wis., Student (Army Sanitation), Carlisle Barracks, Pa.

Edmund G. Wagner, B.S., Univ. Campus, State Dept. of Health, Minneapolis, Minn., Public Health Engineer, Div. of Sanitation

John B. Wallace, B.S., P. O. Box 204, New Martinsville, W. Va., Sanitarian, Wetzel County Health Dept.

Harry W. Weeks, 637 W. Edwards St., Springfield, Ill., Asst. State Director, Com-

munity Sanitation, State Dept. of Public Health

Industrial Hygiene Section

- Knowlton J. Caplan, M.S., St. Louis County Health Dept., Clayton, Mo., Industrial Hygiene Engineer
David M. Gould, M.D., 8302 16th St., Silver Spring, Md., Asst. Surgeon (R), U. S. Public Health Service
Clarence Kooiker, M.D., U. S. Public Health Service, Washington, D. C., Asst. Surgeon (R), States Relations Div.
Cedric Northrop, M.D., 1412 Smith Tower, Seattle, Wash., Tuberculosis Control Officer, State Health Dept.

Food and Nutrition Section

- Helen P. Hostetter, M.S., 620 Mills Bldg., Washington, D. C., Editor, *Journal of Home Economics*, American Home Economics Assn.
Louise S. Moody, B.S., LaMoille, Ill., Nutritionist, State Dept. of Health
Leone Pazourek, M.S., 212 W. Monroe St., Springfield, Ill., Nutrition Consultant, State Dept. of Public Health
Benjamin P. Sandler, M.D., 1224 Walton Ave., Bronx, N. Y., Physician, Navy Yard Dispensary

Maternal and Child Health Section

- Leonard Parente, M.D., M.P.H., 126 Church St., Hamden, Conn., Student, Yale Univ.

Public Health Nursing Section

- Helen Brazonis, 308 W. Walnut St., Carbonale, Ill., Public Health Nurse, State Dept. of Public Health
Martha Buric, Logan County Health Dept., Logan, W. Va., Public Health Nurse
L. Dorothy Carroll, B.S., 305 Euclid Ave., Morgantown, W. Va., Asst. Public Health Nursing Consultant, U. S. Public Health Service
Helen M. Culp, R.N., Box 791, Lawton, Okla., Public Health Nurse, U. S. Public Health Service
Bernadine M. Dougherty, R.N., 149 North St., New Martinsville, W. Va., Clinical Nurse, Wetzel County Health Dept.
Bertie J. Ferrell, Logan County Health Dept., Logan, W. Va., Public Health Nurse
Genevieve E. Finnen, P. O. Box 104, Newport, Ky., Public Health Nurse, U. S. Public Health Service
Virginia V. Hand, 2213 Marshall Ave., Elm

- Grove, Wheeling Station, W. Va., County Health Nurse, City-County Health Dept.
Isabelle R. MacCann, 1512 Virginia St., Charleston, W. Va., Dist. Nursing Supervisor, State Dept. of Health
Helen M. Marcy, R.N., A.B., Box 1263, Lakeview, Ore., Lake County Public Health Nurse
Marguerite A. Maxwell, 205 Maple St., New Martinsville, W. Va., Maternity and Delivery Service Trainee, State Health Dept.
Mary H. Reese, R.N., P. O. Box 974, Las Cruces, New Mexico, County Nurse, Dona Ana County Health Dept.
M. Virginia Welch, 222 E. Oak St., Arcadia, Fla., Public Health Nurse

Public Health Education Section

- Mary K. Ferguson, R.N., 551 Lytton Ave., Palo Alto, Calif., Health Nurse, Stanford Univ.
Donald B. McMullen, Sc.D., 801 E. 13th St., Oklahoma City, Okla., Assoc. Professor, Dept. of Hygiene and Public Health, Univ. of Oklahoma School of Medicine
Dr. Manuel Gonzales-Rivera, Av. El Euzkara 85, Colonia Industrial, Mexico City, Mexico, Supervisor General, Dept. de Salubridad Publica
Adele P. Schlosser, B.A., 839 Howard Ave., New Haven, Conn., Student, Yale School of Public Health
Rachel E. Spinney, M.S.P.H., 65 Wethersfield Ave., Hartford, Conn., Health Education Secretary, Hartford Tuberculosis and Public Health Society

Epidemiology Section

- Martin D. Baum, D.V.M., 116 Temple St., Los Angeles, Calif., City Veterinarian and Director of Milk and Meat Inspection, City Health Dept.
Lt. Commdr. James E. Fetherston, M.C., U. S. N., U. S. S. Seattle, Navy Yard, Brooklyn, N. Y.
John B. Gerberich, M.A., 2350 Fourth St., Cuyahoga Falls, Ohio, Laboratory Asst. in Bacteriology, Kent State Univ.
John S. Kitching, M.D., D.P.H., 453 W. 12th Ave., Vancouver, B. C., Canada, Epidemiologist and Asst. Senior Medical Health Officer, Metropolitan Health Committee

Unaffiliated

- Amos H. Englebeck, 1904 First Central Tower, Akron, Ohio, President, Summit County Board of Health

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

U. S. CIVIL SERVICE COMMISSION

The Commission has announced unassembled examinations for Junior Public Health Nurse at \$1,800 a year and Junior Graduate Nurses at \$1,620 a year, under which the training and age requirements of announcements No. 88 and 103 of 1941 have been amended. Persons interested should communicate with the U. S. Civil Service Commission in Washington or obtain the amended announcements at any first or second class post office.

PHYSICIANS NEEDED IN CANAL ZONE

The U. S. Civil Service Commission announces an examination to secure physicians for clinical service in the Panama Canal Zone. Graduation from a class A medical school subsequent to May 1, 1920, is required, and the applicant must be under 50, 25 to 35 years of age preferred. Entrance salary \$4,000. Persons interested should communicate with the U. S. Civil Service Commission, Washington.

POSITIONS AVAILABLE

Physician with either public health training or experience in local health department administration to serve as health director in a county health department in mid-western state. Salary \$4,000 and \$500 travel (flat rate). Well established department with offices in attractive little city of 10,000. Write Box T, Employment Service, A.P.H.A.

Wanted: Trained Public Health Nurse, starting salary \$1,500 per year and traveling expense, increase to \$1,620 within 6 months. Saginaw County Health Dept., Saginaw, Mich.

Western state department of health will consider applications from physicians to fill four existing vacancies among county health officers, one vacancy in venereal disease control and positions as laboratory technicians. Write Box S, Employment Service, A.P.H.A.

County Public Health Nurses for New Mexico. Must have four months' post-graduate instruction under one of the recognized public health nursing courses and one year's experience. Must drive and have a car. Address inquiry to State Health Department, Santa Fe, N. M.

PUBLIC HEALTH ENGINEER

Responsible professional public health engineering involving field investigations and office studies in the application of

sanitary measures. The more difficult engineering and sanitation field surveys include supervision over public water supplies, sewerage systems and sewage treatment plants and review of plans for same, and promotion and supervision of sanitation programs. Minimum qualifications: Training and experience equivalent to 3 years' civil engineering experience, including 2 years in public health or sanitary engineering; or completion of an academic year of graduate study and a year's experience in sanitary or public health engineering; and graduation from a college of recognized standing with a major course in civil or sanitary engineering. The salary range is \$205 to \$250 per month depending upon experience. Apply Box E, Employment Service, A.P.H.A.

OTHER VACANCIES

Southwestern state health department seeks 2 physicians for assignment to district health units, personally to conduct several small venereal disease clinics on a rotating schedule. Experience preferred but not required. Salary \$3,000, plus actual travel allowance not to exceed \$1,200. Write Box V, Employment Service, A.P.H.A.

The New Mexico State Department of Public Health will consider applications for the position of Assistant Director of the Maternal and Child Health

Division. Address inquiries to the State Department of Public Health, Santa Fe, N. M.

Wanted: Trained Public Health Nurse, starting salary \$1,500 per year and traveling expenses. Increase may be expected within 6 months. Shiawassee County Health Department, Corunna, Mich.

Sanitarian Wanted: Starting salary \$1,800 per year with travel allowance of \$50 per month. Man must have his own car. Bachelor's degree followed by at least one year's course or its equivalent in subjects necessary for one entering the public health field, or an engineering degree plus one year's experience in sanitary or public health engineering required.

A course in public health training may be considered as an equivalent for a part of the experience requirement. Apply Director District Department of Health No. 6, Central Office, Newberry, Mich.

Wanted: Nurse for county health work. Salary \$1,800 per year with travel allowance (additional) of \$500 per year. Address District Health Department 2, West Branch, Mich.

Instructor in Bacteriology, Medical School, large midwestern university, M.D. (or Ph.D. or D.Sc. in Bacteriology); Male. Salary \$1,800 to \$2,500 according to age and experience. Write Box D, Employment Service, A.P.H.A.

POSITIONS WANTED

ADMINISTRATIVE

Teaching or administrative position desired by physician, aged 48. Experienced teacher in preventive medicine and public health, now employed at prominent medical school; 20 years' experience in municipal health administration and epidemiology. A-491

Physician, B.S., M.D., and M.S.P.H., University of Michigan, aged 35, experienced city-county health administration and as director university student health service. Will consider permanent responsible position offering good income. A-492

Physician with 25 years full-time experience in public health administration is available for immediate appointment. Moderately hard of hearing; otherwise fully able. Salary \$4,500 or better. A-497

WOMEN PHYSICIANS TRAINED IN PUBLIC HEALTH

Woman aged 34, M.D., University of Basle, Switzerland, M.S.P.H. DeLamar Institute, Columbia University. U. S. citizen. Excellent references. Especially interested in industrial hygiene. A-493

Woman aged 41, M.D. Columbia University, M.S.P.H. DeLamar Institute, experienced in epidemiology and research, seeks position offering administrative experience. A-494

Woman physician, aged 48, M.D., University of Vienna. Excellent European pediatric experience. Seeks position in pediatrics, administration or statistical research. A-495

HEALTH EDUCATION

Health Educator, Negro, man with background of High School administration and M.S.P.H. from University of Michigan, seeks position in Health Education. Public agency or educational field. Excellent references. H-497

Health Educator, M.A. in Education, 10 years' background in community organization for public health education, also teaching of personal and community health at high school and college levels. Public health nurse, able to teach mental and social hygiene as well as general health education. East preferred. H-498

Teacher and research worker, man, Ph.D., age 52. Extensive record as college professor of biology and hygiene and investigator, for the past two years engaged in research. H-499

Health Educator. Man with M.S. in preventive medicine and public health. Negro. Seeks position in Health Education or field work with official or non-official agency. H-500

Woman with master's degree in health education, 12 years' successful experience in public school and college teaching, administration and research. Will consider position in normal school, public schools, or in official or nonofficial health agencies. Prefers South or East. Available at once. H-501

LABORATORY

Milk Sanitarian and Technologist, age 37, Ph.D., Bacteriology, Wisconsin, 10

years' experience in milk and food sanitation from industrial and official angle, seeks administrative position with opportunity for research or investigational work preferred. L-381

Chemist, Sc.D., Biochemistry, Johns Hopkins University. Age 31. Public health laboratory experience, teaching experience. Desires position with promise of advancement, preferably in commercial organization. L-461

Bacteriologist, young man 28, with B.S. in industrial science, experienced in newspaper work, salesmanship and now employed in state department of health laboratory, seeks position as bacteriologist or doing promotional work of public health nature. L-465

MISCELLANEOUS

Well trained ophthalmologist desires position in public health work. M-450

Veterinary Doctor, M.P.H., University of Pennsylvania, age 27, with two years of practice, seeks position in food, meat, milk, or livestock sanitation with state or local health department. Also interested in teaching position with research facilities. M-451

Public Health Nurse with M.A. degree wishes position in health supervision and teaching in college or public school. West preferred. M-452

Administrative Assistant or Health Educator, woman, M.A. 10 years' experience in health agency offices; 7 years' teaching experience; writer on health and other subjects; experienced in independent research; some training in social work; some hospital experience. M-453

NEWS FROM THE FIELD

THE NUTRITION FOUNDATION AWARDS GRANTS

THE Nutrition Foundation announces that grants for \$125,000 have been awarded for fundamental research in the science of nutrition.

Dr. Karl T. Compton, Chairman of the Board of Trustees of the Foundation, who is also President of Massachusetts Institute of Technology, said that in making these independent research studies possible for the public welfare, the members of the food and related manufacturers, acting together through the Foundation, were opening a new frontier of public service.

George A. Sloan, President of the Foundation, announced the election of the National Dairy Products Corporation as a founder member, and the election of their President, L. A. Van Bomel, a member of the Board of Trustees. Dr. Lloyd K. Riggs of National Dairy Products, and Dr. J. T. Knowles, in charge of the Chicago Laboratory of Libby, McNeill & Libby, were appointed members of the Food Industries Advisory Committee.

Dr. Compton said the Board had considered a large group of applications with reference to three primary objectives, which the Board wishes particularly to support under present conditions:

First: Their contribution to our war effort;

Second: Their immediate advantage to public health;

Third: Their long time advancement of the fundamental science of nutrition—the kind of exploratory research that will lay the foundation for better health and scientific guidance in the food industry of tomorrow.

To date, 22 universities have received grants.

Grants were also made to the Children's Fund of Michigan, Detroit, Mich., the Food and Nutrition Board of the

National Research Council, Washington, D. C., and to the New York State Agricultural Experiment Station, Geneva, N. Y.

UNIVERSITY OF MINNESOTA ENGINEERING COURSE

AN intensive course in public health engineering will be offered at the University of Minnesota under the auspices of the Department of Preventive Medicine and Public Health. This course, which will run from June 15 to August 28, 1942, will bring together in an 11 weeks' term several of the fundamental courses in the regular public health engineering curriculum leading to a master's degree. All courses will be of usual academic quality, and credit so earned will count toward a degree. The courses will consist of lectures, conferences, laboratory exercises, and field demonstrations. The facilities of the Division of Sanitation in the Minnesota Department of Health, as well as of local health departments, will be utilized for student teaching.

Registrations will be limited to graduates in engineering or persons who have had suitable experience in the field of environmental sanitation. All inquiries should be directed to the Department of Preventive Medicine and Public Health, University of Minnesota, Minneapolis, Minn.

MALARIA IN NICARAGUA

PRESS reports in May indicated that Dr. Luis M. DeBayle, the chief medical officer of the Nicaraguan Army and Director of Public Health, has instituted a campaign against malaria as the number of deaths has increased 30 per cent in the past year. Dr. DeBayle was a guest of the American Public Health Association at the 70th Annual Meeting in Atlantic City.

PUBLIC HEALTH ASSOCIATION OF
NEW YORK CITY

THE Public Health Association of New York City held its Sixth Annual Meeting at Hotel George Washington in the Borough of Manhattan on May 13.

The proceedings opened with a panel discussion in the afternoon the theme of which was "Public Health, Social and Legal Problems Connected with Prostitution." Participants in the discussion were the following: Ruth Collins, Superintendent, House of Detention for Women; Dr. Roger E. Heering, Passed Assistant Surgeon, U. S. Public Health Service; Patrick J. Shelly, Chief Officer, Probation Bureau, Magistrates' Courts; Honorable Jeanette G. Brill, former City Magistrate; and Dr. Thomas A. Storey of the American Social Hygiene Association. The moderator of the panel was Dr. Jacob A. Goldberg, Executive Secretary, Social Hygiene Committee of the New York Tuberculosis and Health Association. The audience participated in the discussion.

The following officers were elected to serve until the Annual Meeting in 1943:

President—Helen C. Manzer, Ph.D.

First Vice-President—George T. Palmer, Dr.P.H.

Second Vice-President—Alfred E. Shipley, M.D.

Secretary-Treasurer—Frank Kiernan

New members of the Executive Board were elected as follows:

Arthur I. Blau, M.D.

James M. Dunning, M.D.

J. Leon Lascoff, M.D.

Pauline Murrah

John L. Rice, M.D.

James A. Tobey, Dr.P.H.

Sol Pincus, Deputy Commissioner of Health of the City of New York, was elected as representative to the Governing Council of the American Public Health Association. The Secretary reported that the membership numbered 282.

TRAVELING EXHIBIT—FOOD FOR
HEALTH

BRUNO GEBHARD, M.D., Director of the Cleveland Health Museum, has announced that the following exhibits are available for loan purposes, and the Museum will also make duplicates for any organization or institution wishing to purchase them. Prices for duplicates will be quoted on request.

Protective Foods (Eat Every Day)—No. 101

How Many Calories? (Caloric Value of Favorite Foods)—No. 102

What Do We Need for Work and Play?—No. 103

Why We Eat—No. 105

Food Building Blocks—No. 106

A Nickel's Worth—No. 109

Foods, Facts, and Fallacies (Food Lie Detector)—No. 110

Double Your Food Value for the Same Price—No. 111

The Normal Diet Must Stand 4 Square—No. 115

Since the Museum has no endowment for such loan exhibits, a rental charge of \$5.00 per single unit per week, including time for transportation, must be made.

Units No. 103 (What Do We Need for Work and Play) and No. 105 (Why We Eat) are considered as *double* units, but separate sections may be borrowed as single units.

All exhibits are sent express collect and must be returned prepaid.

Special arrangements can be made for longer periods of time, and for the use of more than one unit.

SAVANNAH DEDICATES NEW MUNICIPAL
HEALTH CENTER

A NEW Municipal Health Center Building was dedicated in Savannah, Ga., on March 25. The three story building, recently completed as a joint city-WPA project, at a cost of \$100,000, houses all of the official and nonofficial health agencies incorporated into the organization known as the Savannah Health Center, directed by the City and

County Health Department, of which Charles C. Hedges, M.D., is director. Those participating included Mayor Gamble of Savannah, who reviewed progress made in the field of health services in the city since the appointment of the first health officer in 1790; Allen H. Bunce, M.D., President, Medical Association of Georgia; Monroe J. Epting, M.D., past President of the Savannah Health Center; and A. J. Waring, M.D., President of the Savannah Health Center. The principal address, "The Health Center and the Health Officer," was delivered by Dr. Harry Stoll Mustard, Director of the DeLamar Institute of Public Health, Columbia University, New York, N. Y.

AWARD OF THE CHANDLER MEDAL OF COLUMBIA UNIVERSITY

FOR outstanding achievements in chemical science Dr. Robert R. Williams of the Bell Telephone Laboratories, New York, N. Y., and his brother, Dr. Roger J. Williams, of the University of Texas, received recently awards of the Charles Frederick Chandler Medal of Columbia University. This medal was established in 1910 in honor of the chemistry professor of Columbia whose name it bears who was one of the founders of the American Public Health Association.

The award to Dr. Robert R. Williams was for his years of work on the isolation of vitamin B₁ and his contributions to the elucidation of its chemical structure. The award to Professor Roger J. Williams was made in recognition of his discovery of pantothenic acid, a powerful regulator of growth, and for his contributions to the knowledge of the vitamin B complex.

TALKS TO THE PUBLIC ON GONORRHEA

MANY physicians will be called upon to give information before groups on gonorrhea. The emphasis placed on eradication of this disease by

official agencies such as the U. S. Public Health Service, and the New York City Health Department will cause lay groups to schedule lectures. Of course, the physicians known to the officers and members will be invited. What to say? Some hints as to the approach to the public health aspects of gonorrhea as a problem for the individual and for the community were given in recent radio talks over WYNC by Herman Goodman, M.D., under the auspices of the Bureau of Health Education and the Bureau of Social Hygiene of the New York City Health Department. Copies of these talks may be obtained by writing to Director, Bureau of Health Education, 125 Worth Street, New York, N. Y., or to Station WNYC. There is no charge.

CHARLESTON COUNTY HEALTH OFFICER

THE Legislature of South Carolina recently enacted a law requiring that the Health Officer of Charleston County be elected with the other county officers instead of being appointed by the County Board of Health. The Medical Society of South Carolina has adopted a resolution expressing "unqualified condemnation" of the requirement.

CENSUS DATA ON SEWERAGE SYSTEMS

THE *Summary of Census Data on Sewerage Systems* appearing in *Public Health Reports*, Volume 57, No. 12, March 20, 1942, pp. 409-421, is available for general publication, though at present reprints are not available.

The material from which the summary was prepared is also available in mimeographed form arranged by states and lists basic data on sewerage systems including detailed information on the rated capacity and methods of treatment of each individual plant and also on the population served (1940), date of installation, volume of sewage treated, populations contributing untreated sewage discharged by individual communi-

ties, and the bodies of water into which both treated and untreated sewage is discharged. A similar census of water treatment plants is now in preparation and will be available in the near future.—From Stream Pollution Investigations, U. S. Public Health Service, East Third and Kilgour Streets, Cincinnati, Ohio

ON MILITARY LEAVE FROM THE ILLINOIS
DEPARTMENT OF PUBLIC HEALTH

ON military leave from the Illinois Department of Public Health are Richard Baxter, Vivian Clarke, R.N., Arnold M. Cohn, M.D., Theodore Cohn, Benedict Corsiglia, Cecil Curtwright, William Dietch, Harold S. Duhamel, Leonard Dworsky, George L. Farnsworth, Harry S. Fein, M.D., M. R. Golly, William A. Hasfurth, William Honsa, Robert E. Hunt, M.D., Paul M. Kiel, Raymond I. Leland, Robert Lynskey, Harold McCormick, C. H. Miller, M.D., Douglas B. Morton, R. S. Nelle, C. L. Nelson, Daniel O'Connell, E. J. Olenick, M.D., Thomas E. Philbin, Carl W. Reh, Walter H. Rieger, Reno Rosi, M.D., Jack G. Sieg, J. F. Shronts, M.D., H. J. Spaeder, and Loren Woodman.

NEW YORK STATE DEPARTMENT OF
HEALTH PERSONNEL CALLED FOR
MILITARY DUTY

MEMBERS of the Medical and Sanitary Engineering staffs of the New York State Department of Health who have recently been called for military duty are listed below, together with the date of commencement of such duty. These are in addition to those whose names were listed in the May JOURNAL.

John E. Kiker, Jr., Assistant Sanitary Engineer, May 13, 1942
Charles Lose, Junior Sanitary Engineer, April 15, 1942
Joseph Salvato, Junior Sanitary Engineer, April 15, 1942
William Smith, M.D., Assistant District Health Officer, May 15, 1942

PUBLIC HEALTH SERVICE LOANS PERSONNEL TO NEW YORK STATE

THE New York State Department of Health announces that three additional physicians and one sanitary engineer have been loaned to the department by the U. S. Public Health Service.

Physicians

Morris J. Stone, M.D., assigned to the Division of Syphilis Control

Abe L. Scheff, M.D., assigned to the New York office of the Health Preparedness Commission

George Alpert, M.D., assigned to the Gouverneur district office

Sanitary Engineer

Arthur Wallach, assigned to the Syracuse branch office.

WEST VIRGINIA PUBLIC HEALTH
ASSOCIATION

AT its recent Annual Meeting, the West Virginia Public Health Association elected the following officers to serve for the next year:

President—Norman G. Angstadt, M.D., Fayetteville

1st Vice-President—Alice Duff, Morgantown

2nd Vice-President—O. R. Lyons, Beckley

Secretary-Treasurer—Dorothea Campbell, Charleston

HOWARD TAYLOR RICKETTS PRIZE

THE Howard Taylor Ricketts Prize of the Division of the Biological Sciences of the University of Chicago, according to *Science*, has been awarded to Dr. Jose Oliver-Gonzalez, a Puerto Rican by birth, Research Associate at the university, in recognition of his work indicating that trichinosis is caused by two forms of parasite and therefore immunity to the disease can be produced only by the formation of two antibodies. The prize was established in 1913 in honor of Dr. Howard Taylor Ricketts of the University of Chicago, who discovered the cause of Rocky Mountain spotted fever. He died in 1910.

THE KELLOGG FOUNDATION'S CONTRIBUTION TO PUBLIC HEALTH IN THE EMERGENCY

THE Kellogg Foundation has announced a plan whereby it will assist students of limited means in public health, medical, dental, and nursing schools to continue their studies during the emergency. The accelerated programs of study in many schools have brought new responsibilities to students who have heretofore depended on vacation and other earnings to help defray the cost of their studies.

Discussions held at a recent meeting of the Association of Schools of Public Health and individual conferences with deans have made it clear that the need exists both for scholarships and for loan funds for students of public health and others.

The Foundation has offered to nearly one hundred and fifty schools of public health, dentistry, medicine, and nursing in this country and Canada the sum of \$10,000 a year in the nature of a gift to each school that wishes to accept it. The funds granted will not be returned. If loan funds are set up by the schools, payments will be made to the school, thus providing a continuing or revolving fund.

The matter of scholarships will be left entirely in the hands of the school. The Foundation will have nothing to do with the selection or approval of the candidates but expects that scholarships will be granted on the basis of scholastic ability, character, and need in comparison with other applicants. It is the hope of the Kellogg Foundation that money so used will be chiefly for the purpose of encouraging exceptional students otherwise unable to enter the field of public health. The only restriction specified is that the scholarships for public health students shall not amount to more than \$800 to any one student in one year.

The Kellogg Foundation is to be

commended for this splendid contribution to public health and related sciences in the war effort. The public health profession can indeed be gratified with this sympathetic understanding of its urgent needs.

THIRTEENTH ANNUAL MEETING OF THE WESTERN BRANCH, A.P.H.A.

THE 13th Annual Meeting of the Western Branch was held in Seattle, Wash., May 26-29.

The following officers were elected for 1942-1943:

President—Donald G. Evans, M.D., Seattle, Wash.

President-elect—Karl F. Meyer, M.D., San Francisco, Calif.

Secretary—W. Ford Higby, San Francisco, Calif.

Treasurer—Guy S. Millberry, San Francisco, Calif.

MISSOURI PUBLIC HEALTH ASSOCIATION

ON May 7 to 9 the Missouri Public Health Association held its Eighteenth Annual Meeting in Kansas City. Approximately 500 members and guests attended the meeting which consisted of general sessions and sectional meetings for health officers, engineers and sanitary officers, public health nurses, and vital statisticians.

The following officers were elected for the ensuing year:

President—Stephen J. Wolff, St. Louis

President-elect—E. A. Belden, M.D., Sikeston

Vice-President—Hugh L. Dwyer, M.D., Kansas City

Secretary-Treasurer—Glen J. Hopkins, Jefferson City

MISSISSIPPI NUTRITION COURSES

THE State Extension Service and the Department of Home Economics of the Mississippi State College, State College, Miss., through the State Nutrition Committee, are sponsoring a series of 3 one day nutrition meetings for three successive months in all the counties of the state.

PERSONALS

Central States

CHARLES F. ABELL, M.D., of Marion, Ind., has been named City Health Officer.

MARVIN F. HAYGOOD, M.D., formerly of the Iowa State Department of Health, has been appointed Chief of the Illinois Division of Local Health Administration, effective July 1.

RICHARD F. BOYD, M.D.,* has returned to Illinois from Topeka, Kans., to serve as Assistant to the Chief of this Division.

ALBERT B. HEADLEY, M.D., of Cambridge, Ohio, has been appointed Health Commissioner of Guernsey County, succeeding MARSHALL J. THOMAS, M.D., of Cambridge, resigned.

ALBERT J. HELM, M.D., of London, Ohio, Health Officer of Madison County, has been given jurisdiction over the unit in Union County under a recently adopted plan merging the two units.

WILLIAM E. HOLMES, M.D., of Omaha, Neb., has been added to the Nebraska State Health Department staff as Medical Health Officer.

HUGO V. HULLERMAN, M.D.,† for 2 years Chief of the Illinois State Division of Local Health Administration, is accepting a position July 1, with the Peoria Department of Public Health as Deputy Commissioner and Director of Maternal and Child Hygiene.

WILLIAM E. JENKINSON, M.D., of Mount Vernon, Ind., has been appointed in charge of the Posey County Health Unit.

THADDEUS M. KOPPA, M.D., C.P.H.,† Assistant Director of Epidemiology, Michigan State Department of Health, Lansing, Mich., has been appointed Director. He succeeds WALLACE M. CHAPMAN, M.D.† who

has resigned to enter private practice in California. Dr. Chapman was named to the position last year.

PAUL E. LANDIS, Associate Professor of Physical Education at Bowling Green State College, Bowling Green, Ohio, has been named State Supervisor of Health, Physical Education, Recreation and Safety, effective March 1. This position was created within the Department of Education to cooperate with federal defense agencies.

CARL B. MCCORD, M.D., of Veedersburg, Ind., is the new Health Officer in Fountain County.

ALLAN J. McLAUGHLIN, M.D.,* Passed Assistant Surgeon General, and recently of the Michigan School of Public Health, is now serving the Illinois Department of Public Health, Springfield, Ill., as Medical Administrative Consultant.

CLARENCE B. RAWERS, M.D., of Bergholz, Ohio, has been appointed Health Commissioner of Jefferson County.

IRA LEO SCHAMBERG, M.D., formerly Research Associate in Dermatology and Syphilology at the University of Michigan, Ann Arbor, has been appointed Supervisor of Venereal Disease Control in the Louisiana State Health Department, New Orleans.

SUE HURST THOMPSON, M.D.,† of West Branch, Mich., has resigned as Director of District Health Unit No. 2, comprising the Counties of Ogemaw, Oscoda, Iosco, and Alcona. HAROLD W. SEFF, M.D.,† of West Branch, is the Acting Director, pending a permanent appointment in June.

WILLIAM ROBERT TIPTON, M.D., of Greencastle, Ind., has been appointed in charge of the Health Unit in Putnam County.

FRED O. TONNEY, M.D.,† of Escanaba, Mich., is Director of the new Delta County Health Center at Escanaba.

FRANKLIN H. TOP, M.D.,* of Detroit, has been appointed by the Detroit

* Fellow A.P.H.A.

† Member A.P.H.A.

Board of Health as Medical Director of the Herman Kiefer Hospital, Detroit.

VERNON M. WINKLE, M.D., of Norfolk, Neb., has been named Director of Health Unit Number 1, covering Scottsbluff, Morrill, and Banner Counties; and Temporary Director of Health, of Unit Number 3, comprising Lincoln and Keith Counties.

ELIZABETH I. WORKMAN, M.D., of Columbus, Ohio, has been named Health Commissioner of Delaware County, filling the unexpired term of GEORGE FREDERICK MOENCH, M.D.,† who went to the W. K. Kellogg Foundation in Michigan.

Eastern States

AUGUSTUS J. HAMBROOK, M.D., of Troy, N. Y., has been appointed Medical Consultant in the Troy Department of Public Welfare, a new position provided for in the 1942 city budget, effective January 1.

REUBEN MUTNICK, M.D.,† of New York, N. Y., has been named Director of the Dodge-Saunders defense area, Nebraska.

JOSEPH SHILEN, M.D.,† of Pittsburgh, Pa., has been appointed head of the Division of Industrial Hygiene of the Pennsylvania State Department of Health, Harrisburg. He succeeds WILLIAM B. FULTON, M.D., M.P.H.* of Harrisburg, who was appointed Chief of the Division of Health of the U. S. Bureau of Mines.

Southern States

BURTON F. AUSTIN, M.D.,† of Montgomery, Ala., has been named State Health Officer, to succeed the late JAMES N. BAKER, M.D.,* of Montgomery. Dr. Austin has been Acting Health Officer. In 1935 he was named Director of the State Bureau

of Hygiene and Nursing, now the Bureau of Maternal and Child Health, a position he held at the time of Dr. Baker's death last November.

JESSIE M. BIERMAN, M.D., M.P.H.,* has resigned from the staff of the Children's Bureau, Washington, D. C., to accept appointment as Chief of the Division of Maternal and Child Health of the California State Department of Health, San Francisco.

REVIS A. BRANNON, JR., M.D., of Utica, Miss., has been named Director of the Southeastern Health District covering George, Green, Stone, and Perry Counties.

CAROLINE H. CALLISON, M.D., of Chatom, Ala., has been named Health Officer of Coosa County, to succeed WILLIAM H. GOFF, M.D., of Rockford, who resigned to enter private practice.

ROBERT L. CHERRY, M.D., M.P.H.,* has resigned as Field Director of Local Health Service, Texas State Department of Health, to accept the position of Director of the Harris County Health Unit, Houston, Tex.

JOHN COLLINSON, JR., M.D., DR.P.H.,* of Baltimore, Md., has been appointed Health Officer of Cecil County, filling the unexpired term of the late CLINTON A. KANE, M.D.,* Perryville, Md.

JOHN W. DAEBS, M.D., formerly Health Officer of Geneva County, Ala., has been named Health Officer of the Oktibbeha County Health Department at Starkville.

GEORGE A. DENISON, M.D.,* Acting Health Officer of Birmingham and Jefferson County, Ala., since September, has been appointed Health Officer, effective February 25.

LOYAL D. FARRAGUT, M.D., of Jackson, Tenn., has resigned as Director of the Madison County Health Unit, to enter Army service.

VERNON W. FOSTER, M.D., of Savannah, Ga., has been placed in charge

* Fellow A.P.H.A.

† Member A.P.H.A.

of the newly created Health Unit of Henry County.

VICTOR P. GENGE, M.D., is the new Director of the Lafayette County Health Department, succeeding THOMAS L. OWINGS, M.D., of Oxford, who resigned to enter private practice in Alabama.

DR. WILLIAM E. GRAHAM, formerly with the U. S. Public Health Service, has been appointed Director of the Division of Venereal Diseases of the District Health Department, effective February 5.

JOSEPH HIRSH,† until recently in charge of health and welfare planning with the Federal Public Work Reserve, Washington, D. C., has been appointed Liaison Officer in the Executive Office of the President, Office of Government Reports, Washington.

ISAAC N. JONES, M.D., of Greensboro, Ala., has been appointed in charge of the Hale County Health Unit, succeeding ELDRIDGE T. NORMAN, M.D., of Greensboro, who resigned to resume private practice.

WILLIAM E. MCILVAIN, M.D., of Charleston, W. Va., Director of the Bureau of Tuberculosis of the State Health Department and for the past 2 years in charge of the State's Mobile X-ray Unit, resigned, April 6, it is reported, to enter the U. S. Navy.

THOMAS B. MCKNEELY, M.D., Passed Assistant Surgeon of the U. S. Public Health Service, Washington, D. C., has been assigned to the Medical Division, Office of Civilian Defense, for duties in connection with the organization of emergency medical services.

JOE H. PRICE, M.D., formerly District Health Officer, McLeansboro, Ill., has been appointed Health Officer of Tishomingo County, succeeding WILLIAM R. ARMSTRONG, M.D., of Iuka, who has entered Army service.

SHALER A. RICHARDSON, M.D., of Jacksonville, Fla., has resigned as a member of the State Board of Health, to devote his time to private practice and to his duties as Secretary-Treasurer of the Florida Medical Association.

STARLING D. STEINER, M.D.,† of Baltimore, Md., has been appointed Chief of the Division of Industrial Health of the Maryland State Department of Health. Dr. Steiner has recently been a member of the U. S. Public Health Service staff.

THOMAS B. TURNER, M.D.,* Professor of Bacteriology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, Md., and Lieutenant Colonel in the Medical Reserve Corps of the U. S. Army, has been called into active service as Chief of the Subdivision of Venereal Disease Control in the Surgeon General's Office.

DEATHS

WILLIAM HENRY BEST, M.D.,* Deputy Commissioner of the Department of Health of New York City, died June 3, at the age of 57.

JAMES D. TRASK, M.D.,† Associate Professor of Pediatrics, Yale School of Medicine, New Haven, Conn., died May 24, in Chicago, Ill., at the age of 51. Dr. Trask had been working as a consultant to the Secretary of War on epidemic diseases, with the aid of staff members of the Yale School of Medicine. On April 22, he and his colleague at Yale, JOHN R. PAUL, M.D.,† Professor of Preventive Medicine, received the John Phillips medal of the American College of Physicians for their research on infantile paralysis. Dr. Trask was graduated from the Sheffield Scientific School at Yale in 1913 and received an M.D. from the Cornell Medical School in 1917.

* Fellow A.P.H.A.

† Member A.P.H.A.

CONFERENCES AND DATES

- American Chemical Society—National Chemical Exposition, National Industrial Chemical Conference. Stevens Hotel, Chicago, Ill. November 17-22.
- American College of Surgeons—Clinical Congress. 32nd Annual. The 25th Annual Hospital Standardization Conference, sponsored by the College, will be held simultaneously. Stevens Hotel, Chicago, Ill. October 19-23.
- American Congress of Physical Therapy—21st Annual Scientific and Clinical Session. Hotel William Penn, Pittsburgh, Pa. September 9-12.
- American Hospital Association. St. Louis, Mo. October 12-16.
- American Public Health Association—71st Annual Meeting. Headquarters, Municipal Auditorium, St. Louis, Mo. October 27-30.
- American Public Works Association. Cleveland, Ohio. October 18-21.
- American Society of Civil Engineers—Summer Meeting. Upper Mississippi. July. Fall Meeting. New England. October.

Number 8

The Epidemiology of Syphilis Based Upon Five Years' Experience in an Intensive Program in New York State*

WILLIAM A. BRUMFIELD, JR., M.D., JAMES H. LADE, M.D.,
AND LOUIS L. FELDMAN

New York State Department of Health, Albany, N. Y.

CLINICAL and laboratory studies of syphilis have given us certain basic knowledge regarding the disease in individuals which, applied to the disease in the population at large, will bring about a reduction in its prevalence if not its ultimate eradication. These facts are: that syphilis is readily transmitted from person to person and rarely by other means; that infectiousness is limited to the relatively early case except in pregnancy, during which transmission of the infection may occur even after many years; that modern anti-syphilitic treatment will render patients temporarily noninfectious promptly and, if continued, will control infectiousness permanently. Obviously the first requisite in planning a program for syphilis control is to have information regarding the disease as a mass phenomenon in

order that these fundamental facts may be utilized most effectively.

Although the value of the individual case report as the basic unit in the collection of morbidity data is well recognized, it is equally well recognized that until recent years at least, syphilis case reporting in the United States has been unsatisfactory. Morbidity reporting has afforded only a partial index of the problem, varying in accuracy from place to place according to the willingness of physicians to report cases voluntarily, and the ability of the health officer to check for completeness of reporting and to procure missing data.

Because syphilis case reporting has been unreliable, it was formerly necessary to resort to other methods for obtaining information concerning the prevalence of this disease. Prior to the advent of the complement-fixation test for syphilis, analyses of records of physicians, clinics and hospitals, and compilation of data from consecutive post-

* Read before the Epidemiology Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 15, 1941.

mortem examinations were the only sources of information. The reliability of the data so collected depended entirely upon the proficiency and interest of the attending physician or pathologist. The introduction of the serologic test reduced the inaccuracies in diagnosis considerably and led to the accumulation of fairly accurate information through serologic surveys of various population groups. The one day survey by questionnaire has provided an additional means of determining the extent of the syphilis problem.

Selection is inherent in varying degrees in each of these methods, but despite such limitations information has been thus secured concerning the prevalence of syphilis, focusing attention on the disease as one of the most important public health problems. Beyond this point, however, the value of such surveys diminishes. It is true that repeated surveys by any of these methods will establish the trend of syphilis, but because of the chronicity of the disease the same patients will be recounted, masking to some extent changes in incidence and prevalence. At best they give us information as to what *has* occurred. They cannot be relied upon for current information upon which specific control procedures may be instituted or altered. The development of a method for the prompt and complete collection of accurate case reports is essential if we are to make the best use of the facilities at our disposal.

On January 1, 1936, the New York State Department of Health inaugurated an intensive syphilis control program, one of the objectives of which has been to obtain complete and accurate case reports for all cases of syphilis coming to the knowledge of health officials from any source. With the passing of 1940, 5 years' experience with this program had been completed. It is our purpose here to discuss the prevalence and trend of syphilis, based

on the data accumulated during this period.

PROGRAM OF SYPHILIS CONTROL

Inasmuch as the procedures for the control of syphilis affect and are in turn affected by morbidity reporting, it is necessary for the interpretation of morbidity data that we understand the conditions under which these data are collected. Inasmuch as the New York State Syphilis Control Program has been described in detail elsewhere we shall not repeat it here. It is pertinent that every precaution was taken during the period under consideration to secure complete and accurate reporting of cases from clinics and private physicians and to remove duplicates of cases previously reported.

In addition to provisions for complete and accurate case reporting, the objectives of the program have been (1) to provide adequate diagnostic and treatment facilities; (2) to provide adequate facilities for investigations of syphilis cases and contacts; and (3) to promote a program for professional and lay education in modern concepts of syphilis and its control.

We shall not go into details regarding activities. It is significant, however, that from 1936 through 1940, the number of serological tests for syphilis increased more than twice; that the clinic sessions and hours were considerably increased, with a corresponding increase in the quantity and quality of the work performed; that 9 counties adopted a plan for providing treatment by private physicians for cases unable to pay; that the distribution of antisyphilitic drugs increased more than 50 per cent; that physicians increasingly took advantage of the facilities for delinquent patient follow-up offered by state and local health departments; and that the consultation service was being used widely by the medical profession. The lay education program reached all parts of

the state, resulting, we believe, in a better public understanding of syphilis than ever before.

PREVALENCE OF SYPHILIS IN UPSTATE NEW YORK

During the 5 year period 1936-1940 there were 79,991 cases of syphilis reported in New York State exclusive of New York City (Table 1). Of these, 71,001 were classified as acquired syphilis and 5,880 as congenital. The type of infection was not known in 3,110 patients. Among the cases reported as acquired syphilis 8,194 were classified as early; 62,260 as late, and in 547 patients the stage of the disease was not stated. Thus, 89 per cent of the total cases reported were classified as acquired syphilis, 7 per cent as congenital, and 4 per cent were unclassified as to type. Of the acquired cases, 11 per cent were stated to be early, 88 per cent late, and in 1 per cent the stage of disease was unknown.

The discussion of these cases will be limited to their distribution by age, and according to the sizes of the communities from which they were drawn. Although the prevalence and attack rates were lower in the female than in the male, their distribution by age was essentially the same for both sexes.

Inasmuch as New York State has a relatively small Negro population, concentrated in two metropolitan areas, about Buffalo, and New York City, classification of the cases by color would not change the picture.

In dealing with the acute communicable diseases, the terms "prevalence" and "incidence" are more or less synonymous. In the case of chronic diseases, however, they have distinct meanings. By prevalence, we mean the total number of cases existing at any one time, including newly acquired infections, and those of long duration. Incidence refers to the number of new infections introduced into the population during a period of time contributing to the total prevalence of the disease. These terms will be so used throughout this discussion.

The total number of cases of syphilis reported in New York State (exclusive of New York City), and rates per 100,000 population, grouped according to age, are shown in Table 2. It will be observed that an appreciable number of cases of syphilis were brought under observation during childhood. The rates were higher for those of less than 5 years of age than for the two succeeding groups. Beginning with the age group 15-19 years there was a sharp

* July 1 estimate based on 1940 census

rise in the prevalence rates, reaching a peak in 1936 and 1937 in the age group 25-29 years, flattening off in 1938-1939 to a peak between 25 and 34 years, and resulting in a definite peak at 30-34 years in 1940. Following the peak prevalence, there was a gradual decline in prevalence rates up to 50-54 years, when in 1936 there was a deceleration of the decline, and in the succeeding 4 years an actual increase in prevalence rates in this group, followed by an uninterrupted decline in the older age groups.

Figure 1 presents graphically the prevalence rates for each of the years under consideration. It is notable that for each year after 1937 there was a reduction in newly discovered case rates for each age group (except for those of 55-59 years and over 60 years in 1938). The decrease was proportionately greater in younger persons, the rates for the 10-14 year age group having declined 52.1 per cent by 1940, those of 15-19 years by 45.5 per cent, of 20-24 years by 44.9 per cent, and for 25-29 years by 39.6 per cent. The decrease in rates beyond this group was less marked, though definite. By 1940

the curve had flattened out so that the rates of reported cases in young adults was only slightly higher than for older persons.

In interpreting these figures, we must first consider the circumstances under which they were obtained. As pointed out previously, all records of cases reported prior to January 1, 1936, were disregarded in building the present case register. The cases reported during 1936, therefore, were drawn from (1) the unknown number of cases under physicians' care at the beginning of the year, together with (2) old cases diagnosed for the first time during the year, and (3) newly acquired infections coming under medical observation. Duplicate reports for patients recorded for the first time within the year were eliminated but no attempt was made to remove duplicate records of those reported prior to the inauguration of the new method. The reporting system in 1936 was more or less in the nature of an annual survey of cases under treatment, except that the identities of the individuals were established. In 1937, the reports included those of old patients missed in 1936 together with new in-

FIGURE 1

NEW YORK STATE, EXCLUSIVE OF NEW YORK CITY
1936-1940

fections of 1937 and those acquired during the previous year but failing to seek medical advice prior to 1937. An analogous situation existed during the subsequent 3 years. These reductions in the figures from year to year do not necessarily indicate a decrease in the prevalence of syphilis, however. They may indicate only the extent to which the "pool" of unknown but already existing cases is brought under treatment. As the size of the "pool" is reduced and as patients are discovered early the curve of total patients should approach that of early ones. It is claimed that this has occurred in Sweden and that reports of new cases indicate the total. We have a long way to go to reach this objective.

The decline in the rates in the young adult groups may be significant. It is

well known that syphilis has its onset with greater frequency in these years. We also know that reporting is not wholly accurate and that errors may be made in the classification of cases. Whether or not the cases represented here are classified as early or late, they represent a potentially infectious group because of the relatively short duration of their infections, and their discovery and treatment should reduce the number of infectious cases at large and thereby reduce the risk of exposure to syphilis. It is encouraging that the reduction in rates has been greater in these than in any other groups. Syphilis in childhood beyond the first few years of life, and in adults beyond the middle thirties is of little importance from the standpoint of syphilis control. The former generally represents a late con-

genital infection, the latter the end results of an infection acquired in younger years. Neither is a danger from the standpoint of infectiousness. Both may be prevented by the control of syphilis between the critical years of 15 and 34.

It is not infrequently stated that, because of the chronicity of syphilis, its prevalence would tend to be greater in older groups because of a cumulative effect. This would be true if it were not for factors tending to reduce the prevalence of the disease in them. Surveys, which our figures support, have shown that the prevalence of syphilis is highest in these groups in which the acquisition of the disease is greatest, and that a decline in prevalence follows very closely the decline in incidence. In other words, beginning with population groups of 35 years and over, the number of cases removed annually is larger than the number added through new infections. There are three factors tending to bring about the reduction of syphilis in these groups, namely, spontaneous cures in the untreated, cures by treatment, and deaths among syphilitics in excess of the non-syphilitics. The degree to which each is responsible has been variously estimated, but is still unknown; their combined effect is considerable.

With this in mind, let us consider the prevalence of syphilis in the 50-54 year age group. It will be noted that the annual rates in this group are higher than in the 45-49 year group except for 1936, the first year of the program. A definite explanation for the apparent greater prevalence in the 50-54 year group cannot be given. It cannot be attributed to newly acquired infections. The number of such cases was very low. Nor does it seem reasonable that efforts at case finding were more productive for this group. Physical incapacitation from late syphilis usually occurs between 40 and 50 years, and

had the disease itself been responsible for bringing larger numbers of cases to light, its effects would have been reflected there. The most likely explanation is that syphilis reached epidemic proportions when the group of persons now 50-54 years of age were young. Further studies are being made to find the answer.

INCIDENCE OF SYPHILIS IN UPSTATE NEW YORK

Let us refer to the reported cases of early syphilis for further light upon the occurrence and trend of syphilis in upstate New York. As indicated previously, early syphilis is defined on the report card as that of less than one year's duration. Such cases after 1936 were subdivided into primary, secondary, or other early, which latter term referred largely to early latent cases.

While the cases in existence prior to January 1, 1936, should not have influenced the number of cases of early syphilis reported after January 1, 1937, there is a possibility of such influence in the "other early" classification. Physicians may report young adults as early cases when no history of a chancre or secondaries has been obtainable, relying upon the probability of a short duration of the disease in these patients. The distribution of these cases, however, is exactly the same as that of primary or secondary syphilis, so we believe that, with few exceptions, cases so reported actually were early.

During the 5 year period 1936-1940, 8,194 cases of early syphilis were reported in New York State exclusive of New York City. Of these, 2,513 were classified as primary, 1,884 as secondary, 1,021 as "other early," and 2,776 of unstated type. Their distribution by years is shown in Table 3.

The distribution of these cases according to age, is presented in Table 4. As would be expected, the attack rates during childhood were low. There was

TABLE 3

Total early	8,194	2,268	2,128	1,706	1,081	1,011

* The type of early syphilis was not designated on the report card in use in 1936.

a marked rise in early acquired syphilis in the 15-19 year age group, peak incidence being reached at 20-24 years. There was relatively little difference in the rates for the latter group and the group 25-29 years. Following this, the attack rates dropped markedly and continued to decrease for subsequent age groups.

These figures are in accord with clinical observations to the effect that syphilis occurs with greatest frequency during young adult life. They further support the premise that control of syphilis among young adults will lead to a reduction of the disease throughout the life span.

Of particular interest is the reduction in the number of early cases of syphilis reported, and the decline in attack rates which occurred in the 5 year period. In 1936 there were 2,268 early cases reported, or 39 per 100,000 population, as compared with 1,011 cases, or 17 per 100,000 population in 1940, a reduction of 56 per cent. This decline was observed for every age group except the childhood groups in which the attack rates were already very low, and the number of cases relatively unimportant.

The decrease in reported early cases from year to year considered alone is not an indication of an actual reduction

The attack rates, shown by the number of early cases reported, (Table 7) followed the same trend as the prevalence rates. It is indicated that a reduction in newly acquired syphilis has occurred throughout the state.

SUMMARY AND CONCLUSIONS

The prevalence and trend of syphilis in New York State (exclusive of New York City) are discussed, based on 5 years' experience with a new method of securing morbidity reports. The data relative to prevalence of syphilis in this state are in agreement with those collected through survey methods, to the effect that syphilis is of greatest importance in young adults, and that

the control of the disease during this time will ultimately reduce it in either extreme of life.

Distribution of cases according to the size of the communities from whence they were drawn, indicates that syphilis is more important in urban than in rural areas.

A progressive decline in the number of cases reported and in prevalence and incidence rates was observed during the 5 year period. It is believed that since this has occurred during a time in which case finding procedures have been more extensively applied than ever before, an actual reduction in syphilis in New York State is indicated.

The Use of Vital Records in the Reduction of Fetal, Infant, and Maternal Mortality*

Operative Procedures for Delivery and Their Effects on Neonatal and Maternal Mortality

THOMAS J. DUFFIELD, F.A.P.H.A., AND LOUIS WEINER, F.A.P.H.A.

Registrar of Records and Director, Bureau of Vital Records and Statistics; and Vital Statistician and Chief, Statistical Division, Bureau of Vital Records and Statistics, Health Department, New York, N. Y.

FOR some time the Bureau of Vital Records and Statistics of the Health Department of the City of New York has realized that the information from vital records can be instrumental, either directly or indirectly, in the reduction of fetal, infant, and maternal mortality, and it has been devoting a great deal of attention to making these vital records as informative as possible.

DIRECT APPROACH TO REDUCTION IN INFANT MORTALITY

So far, the department's direct efforts have been limited to the attempt to reduce the mortality among new-born infants immediately *after* discharge from the hospital. Because it is required that births be reported within two days, it is possible to place sufficient information from birth records in the hands of the visiting nurse so that she can arrange to make a home visit to any mother and child, not attended by a private physician, immediately after their return from the hospital. Every day the Statistical Division of the Bureau of Vital Records sends to each district health

center a list of the births to mothers residing in that district as reported the previous day. These lists are prepared from index tabulating cards and give the name, home address, place of birth, color, and sex of each infant born alive, together with information regarding the number of this child in the family, its birth weight, and whether the case was that of a private practitioner or a general service (ward) case. From a study of these lists the visiting nurse in each district determines just which mothers and babies should be called upon and, should selection be necessary, preference is given to those whose records show that they are either first-born or were underweight at birth.

This service was started in October, 1940, and, whether as a result of it or not, the registration at the well baby clinics in the first two months of 1941 was more than 20 per cent greater than in the corresponding period of 1940.

INDIRECT APPROACH TO REDUCTION IN FETAL, INFANT, AND MATERNAL MORTALITY

Method of Study

In 1933 the New York Academy of Medicine published the results of a

* Read before the Vital Statistics Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

survey of maternal mortality in New York City.¹ It was this courageous report that focused attention on the shortcomings in obstetrical practice in the city and led to the formation of special committees to study the problem in the medical societies of four of the five counties that comprise the City of New York. Subsequently additional committees were appointed by the medical societies in two counties to study the problem of fetal and neonatal mortality.

In order to function intelligently, these committees sought and obtained the collaboration of the Health Department. Since 1936, the Statistical Division of the Bureau of Vital Records has been sending to each committee each week a list of all the cases in which the committee is interested, together with photostatic copies of all birth and death certificates having a bearing on those cases. Thus, in the case of a maternal death, a committee studying maternal mortality receives a copy of: (1) the death certificate of the mother, (2) the birth certificate of the child (if born alive), or (2a) the fetal death (stillbirth) certificate (if the child was born dead), and (3) the death certificate of the child (if the child born alive died before its mother).

A committee studying fetal and neonatal mortality receives photostatic copies of: (1) the fetal death (stillbirth) certificate (if the child was born dead and the fetus had completed 28 weeks of gestation), (2) the death certificate (if the child was born alive and died before completing ten days of life), and (3) the birth certificate of any child described in the item immediately preceding.

The Confidential Medical Report

It was soon apparent that the information given on the certificates of birth and stillbirth in 1936 was of practically no value in shedding light on the causes that led to the death of an infant born

alive or to the death of a fetus before birth. In an attempt to meet this lack of essential information, the senior author of this paper proposed that supplementary medical information for each live birth and fetal death be recorded in a confidential report on the back of the certificate. This proposal was accepted and in March, 1938, a confidential supplementary medical report, utilizing the backs of the birth and stillbirth certificate forms, first came into use in New York City and has been used ever since. It contained information on such questions as:

- Period of gestation (in weeks)
- Length of the child
- Weight of the child
- Complications of pregnancy, if any
- Results of the serologic test for syphilis
- Duration of labor
- Operative procedures employed at delivery and the indications for such procedures

Later, another question was added: whether the mother was a private physician's patient or a general service (ward) case. These questions were formulated after consultations with members of the committees who also assisted in the preparation of the codes used in tabulating and analyzing the information derived from the reports. The medical profession has coöperated magnificently and on only few birth certificates is this confidential information lacking.

Tabulating Technics

In order to make the fullest use of the material thus made available, the obstetrical histories as given in the confidential medical reports on the backs of the live birth and fetal death certificates had to be correlated with the information from the certificates of death of (a) infants who died under one month of age, and (b) women who died from puerperal causes. To do this, two special sets of composite tabulating cards are prepared. The "neonatal mortality composite card" is obtained by

reproducing entirely the punch card recording the birth of each infant who dies during the first month of life; and adding to it certain pertinent information from the tabulating card recording that infant's death.

The "maternal mortality composite card" is obtained by reproducing entirely each punch card recording a puerperal death and adding to that information certain pertinent data from the tabulating card recording the live birth or fetal death associated with the mother's death. Whether the mother died undelivered or her death was associated with a live or dead birth, and, if delivered, the time interval between delivery and death are also indicated on the card.

In our research program we have been guided by the idea attributed to Dr. C. E. K. Mees, head of the Research Laboratories of the Eastman Kodak Company, in the September, 1941, issue of the *Reader's Digest* (page 71). Dr. Mees is quoted as saying: "The thing to do is to let the research man poke his inquisitive nose into some problem that fascinates him, and then follow it from fact to fact, no matter how far off the original track it leads." Acting on this principle we made a number of tabulations; these led to others; and the end is not yet in sight. All are prepared with the sole aim of shedding light on the causes of death among mothers and the babies they are bringing into the world. The results of the first studies of this material, based on the births and deaths occurring in 1939, were published in the *Bulletin* of the New York Academy of Medicine² and *The Child*.³

RECENT FINDINGS

The Sample

In 1940, 107,287 live births were reported in New York City. Of these, 101,141, or 94 per cent, occurred in hospitals; 99,005 were white and 8,282

were recorded as colored. The cards for the white births are tabulated in groups—white males to primiparous mothers, white females to primiparous mothers, white males to multiparous mothers, white females to multiparous mothers, etc. As it was not possible to complete the analysis of the data for all these groups in time for this paper, it was decided to base this report on a group for which the analysis had been completed, namely, first born white males. The "under-weights" were eliminated, since neonatal mortality in children with birth weights under 2,500 grams varies with the weight at birth.³ Because of their peculiarities multiple births were also excluded with the result that the sample analyzed is limited to single white male live first births weighing 2,500 grams or more delivered in hospitals. Because of the special nature of the sample, readers are cautioned against drawing *general* conclusions from the findings here presented.

Use of Operative Procedures

Table 1 shows the frequency of operative or instrumental deliveries by type of institution in which birth occurred; municipal hospital, voluntary hospital, or proprietary hospital.* We find that 47 per cent of all the cases were delivered operatively, if episiotomy is not considered an operative procedure. Operative deliveries were most frequent in the voluntary hospitals where they were used in 50 per cent of the cases; not so common in the proprietary hospitals, with 45 per cent; and least frequent in the municipal hospitals, with 38 per cent. Low forceps was naturally the most frequent type of instrumental de-

* Municipal hospitals are financed by the city and are collectively managed by the Department of Hospitals for the benefit of the indigent poor.

Voluntary hospitals are individual institutions managed by philanthropic non-profit-seeking organizations receiving some financial assistance from the City.

Proprietary hospitals are individual institutions managed by profit-seeking organizations.

† Less than 0.05

In Table 3, taking the total of each type of operative delivery as 100 per cent, we show the percentage frequency with which each of the various operative procedures was used as a response to the several complications of labor or delivery. From this table, we see that in 40 per cent of the cases in which low forceps were employed, they were applied because the doctor elected to do so and gave no other reason; in almost half of the cases they were applied because of prolonged labor; fetal distress and disproportion also were indications for the use of low forceps.

The complications most frequently indicating the use of mid-forceps and high forceps were: deep transverse arrest and persistent occiput posterior, prolonged second stage, and other forms of prolonged or arrested labor—all grouped under prolonged labor.

The four most frequent reasons given for performing Cesarean sections were: inadequate pelvis and oversized fetus—grouped under disproportion—elderly

primipara, and some medical condition in the mother.

In Table 4 we have reversed the procedure of Table 3, and show the percentages of each complication of labor or delivery in which the various operative procedures were employed. In cases of placenta praevia with premature separation, for example, Cesarean section was employed, according to the reports, in 74 per cent, low forceps in 14 per cent, mid-forceps in 8 per cent, and episiotomy only in 4 per cent. Similarly, Cesarean section was the operation of choice in cases of inadequate pelvis (disproportion), with low forceps and mid-forceps following.

Neonatal Mortality

After learning the frequency and the reasons for each type of operative procedure, we were interested in finding if differences existed in neonatal and maternal mortality rates associated with each type of delivery. The results are shown in Table 5 and Chart II. Some

TABLE 5

CHART 2
 Neonatal
 Mortality

of the numbers are small, but there seems to be an indication that the lowest neonatal (under one month) mortality rate, 6 per 1,000 live births, occurred among children delivered when episiotomy only was employed. The group with no operative procedure was not far behind with 8, while a rate of 12 was found among those delivered by means of low forceps. The highest mortality rates were found in the groups delivered by version and breech extraction.

Maternal Mortality

While the number of maternal deaths associated with the births in this sample is small, it appears that a considerably higher maternal mortality rate followed Cesarean section and breech extraction than other forms of operative delivery.

It is entirely possible that the differences in both the neonatal and maternal mortality rates may be due to factors other than type of delivery. The reasons which lead to operative procedures may exert as much influence as the actual procedure employed, or even more.

SUMMARY

We have referred to the unique method of collecting medical information bearing on pregnancy and delivery which has been employed in the City of New York since early in 1938, and to the direct and indirect use the Health Department makes of this information. We have also described the close collaboration between the Bureau of Vital Records and Statistics and the special committees of the Medical Societies in four of the five counties that comprise the City of New York.

We have presented data regarding operative deliveries, based on a sample of 20,479 single, white, male, live first births in hospitals in the city in 1940, showing that:

1. In the voluntary hospitals some operative or instrumental procedure was used in half of the deliveries, and that the municipal hospitals reported the smallest percentage of operative deliveries.

2. The most frequently used operative or instrumental procedures were: low forceps, mid forceps, and Cesarean section.

3. Low and mid-forceps were usually applied because of some form of prolonged labor. The reasons given for the use of Cesarean section were: inadequate pelvis, oversize fetus, elderly primipara, and a medical condition in the mother.

4. Conversely, when some form of arrested labor or fetal distress was encountered, low or mid-forceps were applied. In case of disproportion, Cesarean section was the operation of choice.

5. Children delivered spontaneously, or when only an episiotomy was done, had the best chance of surviving the first month of life. This chance was small in cases of children delivered by version.

6. The highest maternal mortality rates were associated with Cesarean section and breech extraction.

CONCLUSION

No attempt has been made to analyze completely, nor to interpret the findings that have been made this far, but it is hoped that these and similar findings to be gathered as times goes on, may serve the medical profession in throwing light on the causes of fetal, infant, and maternal mortality. It is further hoped that, with such a tremendously large volume of data as is offered by the vital records of the City of New York, the Statistical Division of the Bureau of Vital Records and Statistics may assist the medical profession in reducing all mortality associated with child bearing.

Health Education in Mexico*

ANGEL DE LA GARZA BRITO, M.D., C.P.H., F.A.P.H.A.

Dean, School of Public Health and Hygiene, Mexico City, Mexico

YOU have undoubtedly heard the story about the native and the professor who wanted to cross a swift river. I shall recall it to you: While in the canoe, the professor tried to amuse himself by questioning the native: "Pedro, my boy, do you know botany?" "No, señor," replied the paddler naively. "Oh! you have lost part of your precious life," replied the professor. And then: "My man, do you know astronomy?" "No, señor," answered Pedro very politely. "Oh! you have lost part of your precious life." Again: "Do you know biology?" "No, señor," was the humble answer, and another "Oh! you have lost a part of your precious life," was again and again the comment of our professor after the paddler had replied to questions about his knowledge. When the conversation was over Pedro continued paddling and kept thinking about how many parts of his precious life he had lost for not having learned the many queer things the savant suggested, until they arrived at the rapids and, notwithstanding Pedro's skill, the canoe overturned and into the river went Pedro and our professor. Our savant cried out for help and Pedro swimming asked: "Maestro, do you know swimming?" "No," yelled back the savant. "Then," shouted Pedro, "you have lost your whole precious life."

In our daily life and work we meet

many Pedros and many savants interested only in queer little things; neglecting to learn the important practical facts about health and they drown on one of the many pitfalls in the river of life.

Wherever the remains of past civilizations are studied, there are found vestiges of activities carried on to improve the health of communities by sanitation of the environment and by personal hygiene. On studying our history, concepts of health education in Mexico can be traced, although time and again we learn that the progress of preventive medicine has been delayed by ignorance, prejudice, superstition, and pestilence.

Thus, I shall relate to you one of the episodes in the history of health education in Mexico which has impressed me most:

One hot day in August, 1804, the people of the Noble and Faithful City of Mexico were surprised to see a grand parade headed by the carriage of the Viceroy Iturrigaray. Following him were members of the Board of the King's Physicians, university and school professors, Sires of the Royal Audience, elders and members of the Supreme Courts, judges and noblemen. Rarely had the inhabitants of Mexico seen such a magnificent parade as that which took the road to the orphan asylum. There, in a huge hall, Dr. Alejandro Arbolea, member of the Board of King's Physicians, inoculated with Jenner's vaccinia the son of Viceroy Iturrigaray. But, why such elaborate and expensive display for such a routine

* Read before the Public Health Education Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

matter as vaccination against smallpox? There was a good reason. Drs. Francisco Xavier de Balmis and Antonio Gutierrez, after several months of painstaking work on board two sailing vessels, had succeeded in bringing to Mexico the Jenner vaccinia. The people of the city, on being told by the local physicians that such a procedure as vaccination was not only false but dangerous, were almost incited to revolt and Viceroy Iturrigaray, being convinced that the procedure was based on truth, had his own child vaccinated by Dr. Arboleya. The news spread. Doctors swore that the child would die, but the people knew that the Viceroy would not have exposed his son to such a danger without being convinced of the safety of the vaccine. After that event they were convinced that the procedure was safe, and thousands of them were vaccinated against smallpox.

This drama carried out nearly 150 years ago by Viceroy Iturrigaray had all the features of modern health education—attracting the attention of the public, maintaining its interest, moving it to action, and at the end attaining its goal. Thus, health education in Mexico has developed and progressed with ups and downs under the auspices of governmental agencies. The task is not easy, indeed, it is a very hard one because Mexico, like many other Latin American countries, is essentially rural.

The rural population of Mexico, according to the census of 1930, is 65 per cent of the whole population, and in some states is 80 per cent. The number of illiterates is still high, about 55 per cent. Lack of culture and the prevalence of superstitions, medieval prejudices, and odd habits in rural communities make the solution of health problems extremely difficult. The somewhat inadequate biostatistics show that Mexico still pays a heavy toll in gastrointestinal disorders, respiratory infections, and parasitic diseases. In some regions of

the country high mortality of infants and children is still registered and the number of mothers who are dying demands more widespread public health activities. Undernourishment, bad housing, inadequate water supplies, and sanitation with their inevitable accompaniment of malaria, dysenteries, hookworm disease, tuberculosis, and some other ills cloud the picture of health south of the border. Just imagine for a moment that all the economic, social, and medical problems which you face in some regions of Kentucky, of Georgia, of Tennessee, of Mississippi—even in the mountains of Pennsylvania—are spread over our entire country and you will have a clear picture of the work which we must perform to control morbidity and mortality. However, we are optimistic. On looking back on conditions prevailing 150 years ago, just before Viceroy Iturrigaray started to educate his people through a demonstration, we see that hygiene and sanitation did not exist and that public health has made progress since that time.

Returning again to biostatistics, the infant mortality rate, which in 1900 was 260 per 1,000 living births, was less than 125 in 1938. In 1922 the smallpox death rate was 83 per 100,000, and in 1940 it was 5; the typhus mortality rate in 1931 was 16, and last year was 9; tuberculosis killed 79 per 100,000 in 1922, while in 1938 it took only 55. The whooping cough mortality rate was 256 in 1922, and 153 in 1938. Malaria, water-borne diseases, milk-borne ills, housing, sanitation, and feeding are now better understood and much is being done to solve the difficulties associated with them. In 1900 the expectation of life of a newborn infant was only 24 years, while in 1936 it was 32 to 44 years, depending upon his birth place, or an average of approximately 34 years. This marks steady progress in the increase of the

span of life for a poor country like Mexico, with its heritage of Spanish individualism and Indian fatalism.

That the progress is due only to health education of the masses cannot be stated without reservation, for every one of us is aware that it is difficult to evaluate changes in health conditions and that there is no valid measurement for health education over a short span of life; but there is no doubt that health education in Mexico, as in many other countries, has substantially helped to improve conditions of life.

Indeed, the most obvious measurements of the progress and results attained by health education are: first, the declining mortality rate; second, the duration of life, and ours is longer every decade; and third, the best measure of all, is the extent to which people habitually look to the health and medical agencies for coöperation, help, and advice with relation to health and medical problems. I agree with Bauer and Hull³ that, "When public health work grows and prospers side by side with the effective practice of preventive and curative medicine, we have evidence of a sound program of health education," and I shall add that, when the people themselves willingly give part of their income to support and increase the health and medical services of their community, and fight when these services are taken away, anybody can be sure that health education is in the very heart of the people.

Health education in the past was conveyed through the methods of trial and error, following the example of nature; in the present, the tendency is to apply the sound and scientific method of modern education. When public health work meant epidemic control its keystone was the physician. His work was immunization, quarantine, disinfection, and punishment of those who were reluctant to obey his orders. When later he was obliged to visit homes he found

that the effectiveness of his work could be increased by having a nurse to assist him. The nurse has now replaced the old sanitary inspector with the viewpoint of the policeman, and her educational work has taken the place of the obsolete dictatorial procedures.

Let us examine two different pictures: one in the 18th century and one in 1941. It is the great square in Mexico City; during one of those hot days in May a man is tied to a scaffold. He is in rags, sweating and bleeding, all the women coming from the markets are throwing at him rotten eggs, ripe tomatoes, and all kinds of odds and ends. He was a milk vendor and was found watering his wares. He is paying the penalty imposed upon violators of the city's ordinances.

On the other hand, we are in 1941. Two girls dressed in a well known white uniform knock at the door of two houses in one of the streets of a native village. Smiling faces welcome them; children hang around them; and the girls start their daily work in the homes of those who need them most. They show the people how to bathe the children, how to prepare food; they immunize susceptibles against diseases and do the many things which a public health nurse does. That job is done from the Río Grande to the Guatemala border by about 1,500 nurses, an average of one for about every 12,000 inhabitants.

In 1900, scarcely half a dozen of the states supported nominal health services; in 1927, the Federal Department of Health had 30 health centers. Ten years later the number was 274, well scattered over the Republic. During the present year 450 health centers and 121 rural health units, with nearly 900 health officers and 1,500 nurses and other auxiliary personnel, endeavor to influence the lives and health of the men, women, and children of Mexico, a country of nearly 20,000,000 inhabitants.

The methods they use, the procedures

they follow, are the same as those which you advise. The channels through which health education is carried to the people of our old Mexico are also the same as yours: governmental and private agencies, the school, social welfare organizations, etc. Most of the work is carried on by government officials, using the same materials which you recommend, but on a smaller or larger scale; the printed matter, the lecture platform, the moving pictures, the radio, and the like. We have been following your steps and our technics are not different from yours for, even though the technics of preventive medicine and public health administration are subject to changes and interruptions, their methods, principles, and objectives are fundamentally alike all over the world, and I believe that it is worth while to tell something about our methods of approaching a people full of prejudices, social and religious superstitions, and well rooted personal habits.

Here a nurse is worried, for the chieftain in a village has forbidden her to vaccinate his people because the weather is too cold or too hot. She is chewing gum, waiting for her bus to take her back to headquarters, defeated. An urchin comes near her and for him she makes bubbles and threads with her chewing gum. The child is amused. Others come and watch her performance. A plan occurs to her: a Chiclet to everyone who lets her vaccinate him. A deal is made with the children and after six hours of exhausting work the whole child population and many adults are protected against smallpox, and another chieftain is convinced that the nurse is not trying to play a mischievous trick on his people. Miss Chewing Gum has in her armamentarium another means to put into action when the chance comes.

Over there, a health officer is refreshing himself in the river near a rural village. The mayor has ordered him to

leave town, notwithstanding a severe outbreak of typhoid fever which is ravaging the place and its surroundings. He is using a cake of scented soap. The foam and the scent attract several little rascals who are watching him. He takes one of them into the water and soaps him. The child is delighted and runs to his hut to show his mother how nice he smells. The squaw comes out to the bank of the river and asks for a piece of that nice soap. "All right, if you allow me to protect you and your family against typhoid fever." The result of such an experience was that the officer had to order several boxes of soap to meet the demand for it in that small rural section, even against the will of its backward mayor.

Besides Miss Chewing Gum, Mr. Soap, Sir Water Supply, we have somebody else who has brought about a big change in communities which were indifferent before to preventive medicine. It is Medical Care. In many places people have never been healthy and to talk to them in terms of health was wasting time. To wake them up and to make them interested in health it was necessary to cure them first and allow them to experience the new sensation of being without the burden of disease. After that it is less difficult to approach them and instruct them how to avoid illness. In many communities it is through curative medicine that the practice of preventive medicine has been established during the last six years. In many rural zones, especially the "Ejidos," or agricultural villages which own their fields, the medical services are supported by the settlers themselves.

I agree with Kleinschmidt that at least in Mexico and in most Latin American countries preventive and curative medicine are inextricably interwoven. The merely hygienic aspects of the fight against malaria or hookworm or any other pestilence which is scourging our rural population cannot be

separated from the purely medical implications. Indeed, as Hydrick⁴ and Turner⁵ state, a treated patient is only a passive center of health propaganda, as also are his relatives and friends, but I would add that he can become a potential center of the most active health propaganda if we take advantage of his state of mind after he is rid of disease.

A man who has been cured, who for the first time is enjoying health, is willing to do anything you ask him to do, and from a passive tool of education he easily becomes an active instrument for health propaganda. If our systems of health education appear to be weak because we use curative methods, as we are obliged to do in the rural field, it is because we neglect to strengthen them by correlating and coördinating the ancient curative medicine with modern preventive efforts.

To do that, we must change our medical curricula and teach our future doctors and our nurses about the social and economic aspects of medicine. We must teach them that a patient is not an interesting specimen from the economic or scientific point of view, but a unit, a component of a grand complex called society. Then and only then, they will understand that there is only one rational aspect of medicine, the

integral one to perform our duty faithfully.

The events of the past and the facts of the present demonstrate the need of being critical of our programs of education, and particularly of our plans for health education, to establish a sound understanding of the psychology of our people, and a careful self discipline for our own sake and for that of our brethren. In the meantime we must condemn the inner impulse to be defeated beforehand in our efforts to make an end to disease, war, and misery, and to increase the span of human life. Let us do so, and we shall learn to swim in the river of life and enjoy the swimming in a healthy long river, the life of a democratic and free America, in which we do not hesitate to keep our hopes for a better and a happier world.

Local Responsibility for Housing Control*

CHARLES L. SENN

*Assistant Chief in Charge of Sanitary Inspection, Health Department,
Milwaukee, Wis.*

MUCH of the emphasis on improving housing for low-income families has been placed recently on large scale, subsidized housing construction projects. Perhaps not enough attention has been paid to improving existing housing facilities, and to preventing the creation of additional slums and blighted areas. More rigid enforcement of existing and strengthened housing laws through mutual coöperation of all local agencies and departments can improve conditions materially in areas of poor housing.

Before substantial improvement of such areas can be accomplished, the problem must be considered from an economic viewpoint. Some time ago a letter was received from an official assigned to study the housing situation in his city. His letter began by saying: "Our Relief Department allows a maximum of \$10 per month for rent, in our relief client's budget." The \$10 a month place unquestionably seldom receives a coat of paint, plumbing repairs by a competent plumber, an earnest effort at rat extermination or rat proofing, heating plant repairs, or other essential maintenance services. The place is rented "as is," and the landlord frequently tells his tenants: "If you don't like it, you can move."

The person of means can move without any great economic hardship. Low income groups, however, usually do not have funds to pay for moving, even if a more suitable place were available for the rent which they are able to pay.

Rental income should be sufficient to enable owners to maintain properties in a reasonable state of repair. Then, municipal departments should enforce requirements for proper maintenance, occupancy, and compliance with building, safety, and zoning laws.

It is generally agreed that housing must be subsidized before substantial improvements can be effected. Federal housing projects are most successful in providing almost ideal housing for low income groups. Municipalities cannot, however, depend upon the federal government for curing all housing ills.

Local control of housing involves three distinct phases, building and zoning regulation enforcement, maintenance supervision, and demolition.

CONTROL THROUGH BUILDING AND ZONING LAWS

In Milwaukee, it was realized that some control over the conversion of dwellings was essential. This control now involves the securing of an occupancy permit from the Building Inspector whenever there is a change in the type of use of a building. Before this permit is granted, the proposed occu-

* Read before the Engineering Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

pancy must comply with the zoning, building, safety, and sanitation requirements of city and state codes.

The zoning laws are usually suggested and approved by the Board of Public Land Commissioners before they are enacted by the Common Council. The City Planner is the adviser to and the secretary of this board. Enforcement is by the Building Inspector who is assisted by the Police Department. Police officers post a notice on certain types of vacant buildings, stating that the building cannot be re-occupied without obtaining a permit from the Building Inspector.

City ordinances prohibit any department from issuing permits or licenses involving a new use of a building unless the requirements of the building and zoning laws are first met.

Improper zoning usually creates a problem for the Health Department. Placing too many buildings on a lot leads to crowded conditions which interfere with proper ventilation and light. Noisy, smoky, malodorous industries in the heart of a residential section usually create neighborhood nuisances. Zoning laws will gradually correct conditions existing now because of the lack of zoning control heretofore.

In 1939, at the suggestion of the Building Inspector, a minimum dwelling standards ordinance was passed. This applies to all new or converted buildings which are to be used for dwelling units. The ordinance prescribes minimum sizes of rooms, such as 160 square feet for living rooms, 120 square feet for the first bedroom and 100 square feet for each additional bedroom, and 60 square feet for kitchens.

The minimum dwelling unit must have a total of 280 square feet of floor area. Minimum sanitary equipment is a sink in each unit and one complete bath for each two units. No new light housekeeping units may be created, even in existing buildings or rooming

houses, unless they meet these minimum requirements.

The ordinance prescribes reasonable minimum land areas per dwelling unit. Looking toward the future, this law will do much to eliminate dark, crowded, blighted areas from developing, when what are now new areas are eventually occupied by low income groups.

Blighted areas are developing around the outskirts of cities where building regulations are liberal, laxly enforced or nonexistent. Shacks, bungalow garages, and other makeshift dwellings are erected by the poor. Improperly constructed wells, poorly installed plumbing (if any), and insanitary privies add to the health hazards of poor housing.

Milwaukee county officials state that they were the first in the country to adopt a county-wide zoning law. The county is zoned for agricultural, residential, local business, commercial, light manufacturing, and industrial areas. All subdivision plats are suggested, and must be approved by, the County Planning Department. Zoning permits must be obtained from the county before construction can be started.

All townships within three miles of the Milwaukee city limits have enacted building laws which prohibit the erection of shacks or the use of bungalow garages for more than a limited period of time.

A state-wide well drilling code¹ requiring registration of well drillers, prescribing minimum construction standards, and requiring the filing of a well log and premise diagram, is doing much to eliminate unsafe wells where public supplies are not available. The construction of community wells for subdivisions not accessible to large public water supplies is being encouraged. A state-wide plumbing code is insuring sanitary plumbing installations and reasonably adequate private sewage disposal systems. The Milwaukee Metropolitan Sewerage Commission is pro-

viding sewerage and sewage disposal for a large part of the county. A city ordinance recently enacted, requiring connections with public sewer and water lines when they are available, and requiring sanitary construction and maintenance of privies where sewers are not accessible, will improve housing in outlying sections built before the enactment of county zoning and town building laws.

MAINTENANCE SUPERVISION

After a building is constructed or remodeled in accordance with building and zoning requirements and is occupied, the municipality's responsibility is to insure proper maintenance.² Routine maintenance is largely a sanitation problem consisting of insuring cleanliness, proper heating, vermin control, and freedom from overcrowding. This, in Milwaukee, is a Health Department function.

Occupancy record cards were prepared for each of the 2,500 licensed rooming houses in the city. Rooming house managers are required to keep a copy of this card posted. Each room or apartment is listed by number. The number of persons allowed in each room or unit is specified. Rooms which do not meet the size and window area requirements of the rooming house ordinance are not listed and are not to be rented. Third floor rooms with inadequate fire exits are not licensed or listed, although enforcement is by the Building Inspector. Crowding is limited to the rather liberal requirements of the old rooming house ordinance. The "Minimum Dwelling Standards Ordinance" previously mentioned, is enforced in rooming houses by specifying whether a room or unit may be used for light housekeeping or whether it must be used for sleeping only. No excuse by an operator for installing cooking stoves in sleeping rooms, for permitting overcrowding, or for renting unlicensed

rooms, contrary to the posted card is accepted.

Health Department inspectors report the inadequacy of fire exits, defective wiring, and similar conditions to the Building Inspector. Illegal plumbing is referred to the Plumbing Inspection Department. Orders are issued directly by Health Department inspectors to correct insanitary plumbing. Copies are sent to the Plumbing Inspector so that he may be sure the work is done under permit. Plumbing hazard surveys in all buildings are made a part of general inspection by Health Department inspectors.

Simple cards are used by inspectors on all routine housing inspections. The cards list all general items relating to building maintenance. Items coming within ordinance requirements are checked "O.K." or "Not O.K." Whenever checked "Not O.K.," orders must accompany the cards. If some item under Building or Plumbing Inspection Department is checked "Not O.K.," form notices are forwarded to those departments.

RELIEF AND WELFARE AGENCIES COÖPERATE

In routine maintenance, the coöperation of relief and welfare agencies is especially valuable. The Milwaukee County Department of Public Assistance insists that their clients occupy fit housing units.³ Rents up to \$40 per month, for large families, are occasionally allowed. Quarters for their clients are rated by their housing department according to their scale. Deductions are made for deficiencies in sanitary facilities, room size, window area, general condition of the building, heating, and the like. Places rating from 85 per cent to 100 per cent are allowed full rent according to their scale. Deductions are made for places rating from 65 per cent to 85 per cent. No place rating below 65 per cent will be rented but is referred to the Health and the Building

Inspection Departments for investigation. They refuse to rent unlicensed rooms in rooming houses.

Insanitary, vermin infested, single family dwellings are also reported to the Health Department. When the Health Department does not have the legal power to order corrections, the quarters may be classed as "unfit for use." The Department of Public Assistance then requires the owner to make the necessary repairs or rent is withheld. Relief and welfare agencies have coöperated by providing furniture to enable families to move from crowded, furnished quarters in multiple family units to more desirable unfurnished, approved dwellings.

The Department of Public Assistance employs a housekeeping instructor who teaches untidy tenants all they can absorb to improve their housekeeping methods, including technic of vermin extermination in private buildings where the Health Department cannot require the owner to exterminate.

The Relief Department's success is due largely to their willingness to pay reasonably adequate rent, directly to the landlord. As the owner knows that his rent will be paid promptly each month, relief clients are, in this respect, more desirable than other low-income families.

SOCIAL CENTERS AND SOCIAL AGENCIES

Milwaukee's extensive system of playgrounds, recreation and social centers can be considered a factor in improving the environment in some areas. Within recent years, the number of playgrounds has been increased from 24 to 80. Organized playground activities assist in providing healthful recreation for the children in the crowded and blighted areas. The social center programs, besides providing the usual recreation, offer facilities for special evening activities for young people from homes where proper quarters for entertainment are

not available. These activities are more extensive in areas where juvenile court records show the greatest percentage of minor delinquency.

The social agencies take an active interest in housing. For more than a year, the Housing Committee of the Council of Social Agencies has been studying housing problems from all angles.

CONDEMNATION AND DEMOLITION

Before orders are issued to correct conditions in buildings in poor structural condition, the Building Inspector is requested to determine whether the building is subject to condemnation.

Although Milwaukee's tenement law, enforced by the Health Department, contains the familiar condemnation section, with provision for condemnation placards, this clause has not been used for several years. Condemnation is a Building Department duty.

When old sheds, barns, and abandoned buildings are found by Health Department inspectors to be rat harborage, the Building Department checks to determine whether they may be condemned. In the last 12 year period, 7,337 buildings of all kinds were condemned by the Building Inspector and subsequently razed. Many of these were old sheds and barns, cutting off light and air from living quarters and providing rat harborage. In the condemned and razed buildings were 4,155 dwelling units that were unfit for use.

Much of this condemnation was during depression years when one would expect little rebuilding. Records for the years 1935 to 1937 inclusive show buildings razed assessed at \$469,000. Building permits show new construction on these lots to have a value of \$3,546,000. Contrary to the general belief, the city's assessable property values were increased rather than decreased as a result of condemnation.

Condemnation proceedings have a

good effect on general building maintenance. Undoubtedly the number of buildings condemned would have been substantially greater if owners had not realized that they must keep buildings repaired or tear them down.

WPA real property surveys have been made in Milwaukee as in many other cities. Their records show that according to their standards an average of 13.8 per cent of the buildings in 202 other cities are unfit for use. Their report for Milwaukee shows 0.7 per cent of the buildings as unfit for use.^{4, 5}

It is reported that when federal authorities studied Milwaukee housing conditions, they agreed that there was no single area that should be cleared to permit the development of a housing project. The one housing project of 518 units in the city of Milwaukee, built under PWA, is located in an outlying area. Early federal housing requirements, making certain minimum incomes mandatory, and placing the rent beyond the means of the poor, have done much to discourage further federal housing projects in the city.

There is no housing authority in Milwaukee, although state laws permit the creation of one. By coöperation, the planning, building, health, relief, social center, and welfare agencies in Milwaukee have made progress toward improving housing.

City health, building, planning, and tax departments are coöperating with the ward alderman in a study of housing conditions and factors in what is probably the most blighted section of the city, the colored district. These departments are also coöperating with the Wisconsin Anti-Tuberculosis Association in their large scale intensive tuberculosis study of the colored people. Possibly the results of this work will be conclusive enough to warrant prompt public action. This may be an area for large scale demolition and a public housing project.

"Neighborhood Re-development Corporations,"^{6, 7} similar to those being developed in some other states, might also prove successful in reclaiming certain blighted areas.

Difficulty in obtaining loans for extensive improvement of and for remodeling older buildings is one factor hindering progress. Liberalization of federal lending agencies' policies or the creation of local public loan funds would do much to improve living conditions in many older buildings. Public or subsidized privately built housing on vacant, city owned property, even though large areas for large, complete developments are not presently available, might be desirable in certain districts.

Landlords should do more to encourage tenants to make repairs, do painting and other maintenance. Too many tenants in low-cost housing fear an increase in rent if their quarters or premises "look too good."

Perhaps, with the present emergency, progress in improving housing will be retarded. Defense booms should not necessitate lowering standards too far. Public and private agencies should look forward to utilizing much of our national energy and resources after the emergency to building, reconstructing, and improving housing. In such programs improvements for existing buildings should not be overlooked because of concentration on new projects alone.

Health departments, while they cannot and should not expect to do the whole job, can assume a position of leadership in encouraging coöperation between all interested departments and agencies in the important task of providing improved housing in the communities they serve.

IN 1927, culminating the years of continuous struggle of Dr. Chevalier Jackson, a national law was enacted requiring the label "poison" to be placed on all commercial products containing lye and other caustic chemicals. In spite of similar laws enacted by the various states before and after this date, burns due to lye ingestion with resultant esophageal strictures continue to be a serious public health problem. Thus Vinson (1927) reported that 102 of the 186 esophageal strictures seen at the Mayo Clinic were due to the ingestion of lye. Taylor reports 53 lye poisoning cases in Pennsylvania for the year 1934. He also points out that many new caustic preparations have been placed on the market since the Federal Caustic Act was enacted—such household helps as drain pipe cleaners, paint brush cleaner, and paint remover. However, his data indicate that in spite of these new preparations, and increased advertising, lye cases have been reduced somewhat in number.

Martin and Arena (1939) reported a study of 48 cases of esophageal strictures seen at Duke University Hospital in the preceding eight years. It is evident from their report that lye ingestion continues to be an important source of esophageal strictures. Legislation has failed to eliminate this problem. A part of the difficulty arises from the fact that

the Federal Caustic Poison Act (1927) in referring to lye defines dangerous caustic or corrosive substances as any containing 10 per cent or more of sodium or potassium hydroxide. Products used for household purposes containing such amounts of lye must be labeled poison. Products containing less than 10 per cent lye do not come under the Act.

Lye poisoning is not one of the diseases which is required by law to be reported. A number of reports of lye poisoning are scattered throughout the literature, but fail to give an adequate picture of the extent of the problem in the United States. The present study has attempted to gather these data in order to form a basis for rational preventive procedures.

METHODS

An attempt was first made to ascertain lye ingestion morbidity and mortality from records of the country's 48 state health departments. Practically no detailed information was secured from this source in view of the fact that, although lye poisoning is a reportable entity as a cause of death, in state summaries it is included under the general heading "acute accidental poisoning by solids or liquids." Deaths due to lye ingestion are usually not reported as such but grouped as "accidental

poisoning" or merely "stricture of the esophagus." Frequently no mention of causative agent is given. Lye poisoning morbidity is not required by law to be reported to the health authorities.

Inasmuch as state vital statistics records provided such a paucity of data, it was decided to send questionnaires to a number of hospitals in each state. Letters were written to four or five or more of the larger and more prominent hospitals in each state. They were requested to send data on the total number of lye cases treated each year, together with the total hospital admissions. Data were also requested upon the race, sex, age, and financial status of the patient while in the hospital. The larger and more prominent general hospitals only were questioned, because it was felt they would furnish more data, their records would be more available, and it appeared possible that lye stricture cases would gravitate to them. It is recognized that the hospital samples and data are not entirely representative inasmuch as small hospitals, due to the inadequacy of their records, were not included in the study. It was thought that case duplication might be a complicating factor if numerous small hospitals were also included in the study. The hospitals responded admirably, and some data were received from most of them. Our data are admittedly incomplete both in numbers and desired detail. To our knowledge, however, they represent the first attempt to study the problem on a nation-wide scale.

RESULTS

Distribution of Lye Poisoning in the United States

A total of 1,334 cases of lye poisoning were reported in a total of 9,184,055 hospital admissions by the 181 hospitals during 1914 to 1939, inclusive. Therefore, for the 181 hospitals as a whole over the period studied, lye poi-

soning accounted for 14.5 per 100,000 of the hospital admissions. The year in which the lye poisoning occurred was given in 1,031 of the 1,334 cases reported. They are tabulated in Table 1. A casual inspection of this table suggests a gradual increase in cases. Whether or not this is real cannot be stated, as the yearly admission figures for the hospitals reporting these cases are not available. Part of the increase in reported cases is no doubt due to improvement in hospital records. It may also be due in part to increased bed capacity of some of the hospitals and to the trend toward hospitalization in the United States. It is apparent, however, that the Federal Statute enacted in 1927 did not eliminate lye poisoning. The average yearly number of cases reported by the hospitals in the study group from 1920 to 1927 was 22, while from 1928 to 1939 it was 67. There were 303 lye cases reported without information on the year of their occurrence. Whether or not these cases had a peculiar time distribution which would affect the trend in Table 1 is unknown.

TABLE 1

Cases of Lye Poisoning Reported by the 181 Hospitals Coöperating in the Study

1914	1	1927	27
1915	1	1928	29
1916	10	1929	36
1917	12	1930	42
1918	14	1931	59
1919	12	1932	55
1920	18	1933	61
1921	19	1934	83
1922	19	1935	81
1923	18	1936	107
1924	23	1937	103
1925	29	1938	85
1926	24	1939	63

During the period 1914-1939 the 181 hospitals included in this study admitted 1,334 cases of lye poisoning among a total of 9,184,055 hospital admissions. In the year 1939 there were 9,879,244

hospital admissions in the United States. If the proportion of lye poisoning cases to the hospital admissions in 1939 remained the same as it was during 1914 to 1939 it follows that in 1939 there were at least 1,430 new cases of lye poisoning in the United States. However, since our study included data only from general hospitals, whereas the total hospital admission for 1939 includes hospitals for the insane and tuberculous, it is very likely that the total cases of lye poisoning would be less than 1,430. These figures represent only those seeking hospital care. There are no doubt many cases which did not come to the hospital but were treated by physicians in their offices.

The geographic distribution of the cases reported by the 181 hospitals included in this study is shown in Table 2. On the basis of experience in these institutions, hospital admission rate for lye poisoning cases per 100,000 patients is given for each state. The State of Utah had a rate of 411.8 cases of lye

poisoning per 100,000 hospital admissions. The data from this state were too few, however, to be of any significance. Study of Table 2 shows that, except for the District of Columbia with a rate of 111.7, the southern states Tennessee, North Carolina, Florida, South Carolina, and Georgia have the highest rates (61.4 to 85.9 per 100,000 hospital patients). On the other hand, Mississippi with a rate of 8.0, and Louisiana with 13.7, are typically southern states with low rates.

The hospitals queried in 7 states—Rhode Island, Vermont New Hampshire, North and South Dakota, Nevada, and New Mexico—did not report a single case of lye poisoning in a total of 449,886 hospital admissions (Map I).

Pennsylvania reported the greatest number of lye cases, 283. As they were distributed among 1,681,711 hospital patients, the lye poisoning rate was only 16.0 per 100,000. It is quite possible that Pennsylvania's rate as well as the rates of other states, with physi-

cians and hospitals noted for the care of esophageal obstructions, is unduly great due to influx of patients to these centers. The data furnished by the hospitals unfortunately were not sufficiently detailed to permit us to allocate patients to place of origin. Hence it is impossible to estimate the effect of this factor on the lye poisoning rates of the various states.

It is perhaps somewhat illogical to

calculate lye poisoning rates upon hospital admission rates. The hospitalization rate varies greatly from state to state. For example, in Washington, D. C., the yearly hospitalization rate is 19 per cent of its total population, in Georgia it is 5 per cent. It is evident that such great variations in hospital rates in part, at least, indicate that there is a tendency in certain areas to go to the hospital for many illnesses

rather than to remain at home. For certain serious conditions such as operations and lye strictures, it is quite likely that hospitalization rates are rather uniform throughout the country. Variations in the general hospitalization rate influence greatly the ratio of lye poisoning admissions to total admissions. Thus, if the southern states have a low per capita general hospitalization rate, yet if all the lye poisoning cases go to the hospital the lye poisoning admission rate would be relatively high. On the other hand, a state with a high general hospitalization rate would have a correspondingly lower ratio of lye poisoning admissions to general admissions.

A correction was therefore made for the variation in general hospitalization rates in the several states. This was done by multiplying the hospital admission rate* of the state by the lye poisoning admissions rate. Thus states which had a high lye poisoning admissions rate due to the fact that the general hospital admission rate was low, showed a reduction in the final lye poisoning rate. For example, in North Carolina the lye poisoning cases admitted to the hospitals queried represented 81.6 per 100,000 of hospital admissions. Now North Carolina has a relatively low general hospitalization rate which in turn results in relatively higher lye poisoning rates. The adjusted lye poisoning rate for North Carolina becomes 20.4. The adjusted rates for the various states are shown in Table 2. This correction in general resulted in a reduction in the lye poisoning rate in southern states with a low general hospital admissions rate. Even with this correction the southern

states still showed the highest lye poisoning rates.

Grouping of the lye poisoning into the generally used nine divisions of the United States further emphasizes the more common prevalence of this condition in the South (Table 3).

TABLE 3

Hospital Admission Ratio for Lye Poisoning per 100,000 General Hospital Admissions in Nine Areas

	Cases
New England States	2.4
Pacific States	6.8
West North Central States	9.3

West South Central States	25.4
South Atlantic States	34.9

RACE

There were only 349 cases upon which data were available as to age, race, and sex (Table 4). A total of 249 cases were white (71.6 per cent), and 100 (28.4 per cent) were colored. Inasmuch as the Negro race constitutes approximately 12 per cent of the total population in the United States, and yet appears to account for 28.4 per cent of the lye poisoning cases, it is apparent that this condition is more common among them than among the whites. This is especially apparent if one compares the ratio of lye poisoning reported among white and Negro children under 5 years of age (Table 4). In this particular group, 61 per cent of the cases occurred in white children, and 39 per cent in Negro children. In other words, it was 4 times as common in Negro children as in white children when the racial populations are taken into consideration. Ignorance, crowded living conditions, and carelessness are no doubt factors in the high Negro rate. Another factor responsible for the high Negro rate is their rural distribution.

* The hospital admission rate of the District of Columbia was 0.19. Since this hospital admission rate was the highest encountered, it was given the value of 1.0 for computation of the adjusted lye poisoning rate, and the other states' calculations were made accordingly.

AGE

Lye poisoning is 2 to 3 times as prevalent among rural persons as urban inhabitants. This is largely due to the habits of house cleaning and soap making of rural southern inhabitants.

Our figures indicate that the greatest percentage of the lye poisoning in both races occurs in the group under 5 years of age. Sixty-five per cent of Negro cases occurred in children under 5 years of age. In the whites, on the contrary, only 41 per cent occurred in children under 5 years of age (Table 4). Two possible explanations are suggested both of which may play a rôle in this age distribution of lye poisoning. The amount of lye swallowed by Negro children may be greater than that usually swallowed by white children and therefore medical and hospital care are sought at once. Among both the whites and Negroes there may be instances where the amount of lye swallowed is so small that hospitalization is not immediately necessary. Hospitalization may therefore come a number of years later due to a slowly progressive stricture. In such instances the case might be classified under the age of onset rather than the age at which the lye was ingested. In fact a number of our records indicate the lye stricture for which the patient was hospitalized dates to lye ingestion some years previously. A second possibility accounting for the higher lye poisoning incidence in whites

in later life is the more common use of this material for suicidal purposes by the white race.

An analysis of the age incidence of lye poisoning in the 0-4 age group demonstrates that children under 1 year of age seldom are affected. One and 2 year olds are the ones most commonly poisoned, although all ages through the 5-9 year group furnish numerous cases. The frequency of attack then falls off until the 20-24 year age group is reached. Beginning at this age and extending through the next 40 years there is a continuous moderate amount of lye poisoning, especially among the whites. This increase in lye poisoning in adults may in part be due to late manifestations of lye poisoning incurred in childhood. Our data, however, indicate that a considerable amount originates in adults and to a large extent as a result of attempted suicides.

There were 60 persons over 12 years of age whose history gave the method of poisoning. In only 3 instances, 5 per cent was "accidental" definitely given as the cause of lye ingestion. There were 5 cases which were called "recent" and possibly all of these 5 could have been accidental—though this is not probable. Should one consider, however, all of these "recent" cases due to accidental cause, even then lye accidents by adults, in this case over 12 years of age, would amount to

TABLE 4
Distribution of Lye Poisoning by Age, Sex, and Race

Age		Under 1	1	2	3	4	0-4	5-9	10-14	15-19	20-24	25-34	35-44	45-54	55-64	65+	Adult	Infant	Under 4	Total

only 13.3 per cent—quite different from the 100 per cent accidental ratio found in the study of lye cases in children. To sum up the adult lye poisoning cases we find 66.7 per cent of them were due to suicide, 20 per cent were poisoned as children, and possibly 13.3 per cent were accidentally poisoned as adults (Table 5). In the study of adult cases (over 12 years of age) at Duke Hospital, where a more careful investigation could be made of the method of poisoning (but with the disadvantage of having far fewer cases), it was found that 18.2 per cent of adults had taken lye by accident as an adult, 45.4 per cent had taken lye by accident as a child, and 36.4 per cent used lye with suicidal intent (Table 6).

TABLE 6

Analysis of Eleven Lye Cases at Duke University Hospital in Persons Over Twelve Years of Age

<i>Reason for Poisoning or Time When Poisoned</i>	<i>No. of Cases</i>	<i>Per cent of Total</i>
Poisoned "when child"	5	45.5
Suicide	4	36.4
Poisoned by "accident"	2	18.2

A total of 40 instances of suicide by lye ingestion were reported. Thirty-eight (95.0 per cent) of the 40 suicide cases were white, 2 (5.0 per cent) colored. White females were responsible

for 22 (55.0 per cent) of the suicides, white males for 16 (45.0 per cent), colored females and males each responsible for 1 (2.5 per cent). Since lye is a substance used more often by the poorer classes, it is not surprising that 70 per cent of these suicidal cases entered the hospitals as charity patients, while only 14.6 per cent were private patients. The financial status of 15.4 per cent of the patients was not given.

SEX

Lye poisoning as reported was slightly more common among white females than males and more common in Negro males than among Negro females. Our data show that among the whites, 48.2 per cent of the cases were males and 51.8 per cent females, among the Negroes 53.0 per cent were males and 47.0 females. It is impossible to state why the rate for white males should be less than that for the females while among the Negroes the males had a greater lye poisoning rate than the females. The difference in lye poisoning rates of the sexes is very small, however, and more data are needed before any significance can be attributed to these apparent differences. One might have expected a higher rate among the females than the males inasmuch as the former spend more time in the home and theoretically should have a greater exposure to accidental ingestion. This may be balanced by the fact the females usually prepare the lye for use, are familiar with it, and hence avoid its accidental ingestion. Study of the incidence of lye poisoning among children under 5 (Table 4) also indicates no appreciable sex difference.

LYE ACCIDENTS

All the cases of lye poisoning in our series can be placed into two groups: accidental and intentional. The former group includes persons of all ages who

by accident ingested lye. The latter group, taking lye intentionally, were attempting suicide. This latter group is composed almost exclusively of adults.

Accidental lye poisoning was frequently due to ingestion of the powdered lye mistaken for salt or sugar. Even more common was the drinking of lye solutions which were mistaken for milk or sugar water. Classification of 53 cases upon which data concerning the type of material ingested were available indicates that 45.3 per cent of the patients had swallowed lye solution; 24.5 per cent had ingested powdered lye; 30.2 per cent were merely stated to have "swallowed lye."

The following excerpts from lye poisoning case histories indicate how the accident took place.

Powdered Lye:

- "Lid of lye can put in mouth."
- "Spoon containing lye put in mouth."
- "Pellets of lye swallowed."
- "Picked up lye can and started eating contents."

Lye Solution:

- "Solution mistaken for drinking water."
- "On wash day."
- "Drank 'sugar water' from glass which once contained lye."
- "Solution of lye and water put on potato and eaten."

Our data and a review of the literature show that lye, or its preparations, have been mistaken for the following: cough mixture, drinking water, sugar, medicine, milk, epsom salts, wine, and coffee.

Histories of the majority of accidental lye poisoning in children indicate that the lye was being used in solution for washing of clothes and floors or making soap. These solutions or lye pellets were carelessly left within reach of children.

Intentional, is to a large extent a problem of families in the low income group. A total of 239 of 284 cases (85 per cent) upon which the financial status of the patient was given were charity patients. Those taking lye for suicidal purposes were charity patients in 70 per cent of the instances. The cost of hospitalization and treatment were assumed by the hospitals, local charity, or local governments. That this expense may be rather great is indicated by the findings of Martin and Arena. They reported that 68 per cent of the lye poisoning cases studied by them required an average of 48 days hospitalization. Sixteen per cent of the patients were hospitalized 1 to 6 days, and the remaining 16 per cent were followed in the dispensary. In addition to the immediate hospital treatment, the patients frequently must return over a period of months and even years for dilatation of esophageal strictures. Thus the total expense of an accidental lye poisoning may be a matter of several hundred dollars.

PREVENTION

Our data indicate that the prevention of accidental lye poisoning is largely a matter of eliminating this substance as an accidental item of diet or beverage of children. Children under 5 years of age are especially involved in this problem. Adult and child education would appear to be the first logical step in the prevention of lye poisoning. Education of the adults is important because they are responsible for using the lye preparation and carelessly leaving the material lying about. They should be informed of the usual household chemicals that contain lye or caustic materials and also the grave dangers and consequences of ingesting these materials. In addition to stressing prevention of poisoning, it should also be emphasized that if poisoning does take place, whether the

LYE POISONING—AN ECONOMIC PROBLEM

Lye poisoning, both accidental and

burn appears mild or severe, a doctor should be consulted at once. Apparently mild caustic burns frequently result in severe strictures later unless the proper treatment is instituted early. Children should be warned about eating unfamiliar materials or drinking "water" or "milk" that has been standing around. The educational program should consist of an educational leaflet on lye prevention for general distribution by health organizations. Prevention, first aid, and the necessity of medical attention should be stressed. Likewise, placards for school use should be prepared. This material should be distributed especially widespread in rural areas. This material could be prepared by the health departments. Education of Negroes is particularly needed as this race has an unusually high lye poisoning rate.

Education as to the dangers of lye poisoning should be included in the health instruction given in school. Lye preparations should be demonstrated to the children in the classroom to familiarize them with their appearance.

SUMMARY

Accidental lye poisoning with resultant esophageal strictures continues to be a problem of considerable impor-

tance. In general, this condition is somewhat more prevalent in the southern states than in the remainder of the United States. It occurs relatively much more frequently in Negroes than in whites, and is more common in rural than urban areas. By far the greatest incidence of lye poisoning is in children from 1 to 5 years of age. Males and females are equally affected. It is rarely encountered in children under 1 year of age.

Months of treatment are necessary for cure of lye strictures of the esophagus. The majority of patients are in the economic group that cannot pay for the extended treatment that is necessary.

Prevention of accidental lye poisoning consists of continuous education of adults and children as to the dangers of ingesting the substance, and the necessity of medical care if lye is ingested.

Public Health Planning for War Needs: Order or Chaos?

FRANCES SULLIVAN, M.P.H., AND MILTON ROSE,
M.D., DR.P.H.*

*Instructor in Public Health; and Professor of Public Health, School of Medicine,
University of Pennsylvania, Philadelphia, Pa.*

TO be bewildered or encouraged—that is the question raised by the rapid flow of press releases on federal public health activities. Are the many changes in national health organization during recent months indicative of confusion and mismanagement or are they signs of healthy adaptability? This question is as vital to public health workers outside the official services as it is to government personnel.

The United States Government *Manuals* rapidly become obsolete in so far as the machinery of public health administration is concerned. Probably some of the observations contained herein will also be obsolete before they are read. However, the long-term goal of present developments is not foggy. Neither are the procedures followed in efforts to harmonize the work of the many branches of government which affect public health as desultory as they might seem to a totalitarian.

The tempered man of experience as well as the tyro asks, "What do they do—this ODHWS? this OCD? What about the Red Cross? What are their functions? Where does the Children's Bureau come in?"

A major development has been the creation and the rapid growth of the

Office of Civilian Defense (May 20, 1941) and of the Office of Defense Health and Welfare Services (September 3, 1941). Both, along with many other divisions, boards, and offices, are in the Office for Emergency Management, which is directly under the authority of the President through his Executive Office. It would not be illogical to include responsibilities of the Office of Price Administration and the Division of Priorities if one were being all-inclusive about the protection of health in the nation at war. Contributions to public health from the Office of Scientific Research and Development are highly significant also. The present discussion, however, is confined to the Office of Defense Health and Welfare and to the Office of Civilian Defense, two organizations which are working more directly with public health problems as they are more usually conceived even in their broader aspects.

Inevitable shifts in needs require reconstruction and invention of machinery. Public health problems in America are profoundly affected by the vast movements of population and wealth which are occurring. Not only geographic transpositions but also inevitable vocational and avocational re-alignments are produced by sudden and drastic changes in the immediate goals of the great majority of those human beings who are the American People.

* Recently appointed Medical Director, Pacific Coast Area of American Red Cross, San Francisco, Calif.

Accelerated needs in public health run in two directions: first, those changes in emphasis in and continued development of the regular public health services which have expanded rapidly since 1935; second, preparation for local emergencies which arise from enemy action. Although there is interlocking, perhaps some overlapping, and also wide variation of operations as they affect local communities, the Office of Defense Health and Welfare Services seeks, by and large, to cope with the first and the Office of Civilian Defense with the second.

That both of these Offices also render many other services not directly concerned with public health is a significant sign of the times. The medical and engineering phases of public health are still the easiest to understand and are of first importance in the event of enemy action. However, the wide economic, sociological, psychological, and legal bases on which the well-being of the country rests are now placed in an administrative perspective which indicates imagination and courage.

OFFICE OF DEFENSE HEALTH AND WELFARE SERVICES

Organization—The Office of Defense Health and Welfare Services, directed by Paul V. McNutt, superseded the Office of the Coördinator of Health, Welfare, and Related Activities. The Office utilizes the facilities of the central Federal Security Agency services, such as legal counsel, personnel and business management, and information service. Its Interdepartmental Advisory Council is composed of representatives from 20 federal agencies, including the constituent agencies of the Federal Security Agency (Office of Education, Public Health Service, Social Security Board, National Youth Administration, and Civilian Conservation Corps) as well as other federal agencies, notably the Children's Bureau. This Council

advises the Director on major policy questions. Committees of specialists in the respective fields from public and private agencies, professional associations, and other interested groups have been set up on Health and Medical Care, Procurement and Assignment Service (for physicians, dentists, and veterinarians), Family Security, Social Protection, and Community Organization.

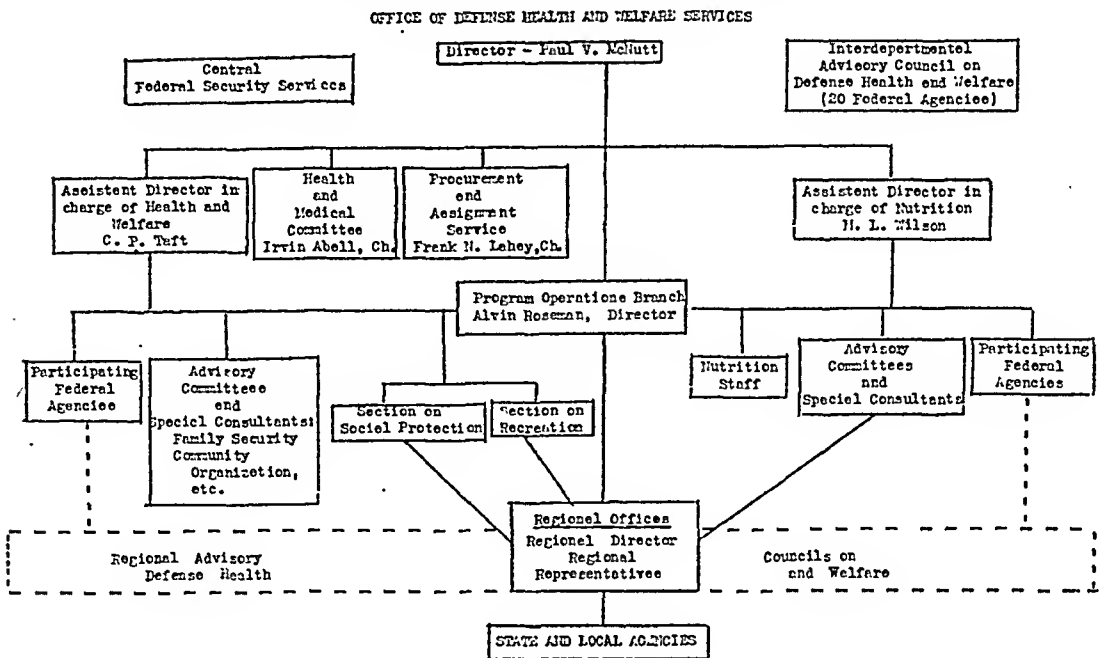

In each of the 12 geographic regions of the Social Security Board there is a regional Advisory Council corresponding in structure and function to the Interdepartmental Advisory Council at the federal level. The regional directors of the Social Security Board act as Regional Directors of Defense Health and Welfare Services and serve as chairmen of the Regional Advisory Councils.

Within the central office there are four main functional subdivisions: Division of Health and Welfare, Division of Nutrition, Health and Medical Committee, and Procurement and Assignment Service. The field programs of the Office of Defense Health and Welfare Services are integrated through the Program Operations Branch, of which Alvin Roseman is Director.

The Division of Health and Welfare is under the direction of Charles P. Taft, Assistant Director, and Geoffrey May, Deputy Assistant Director. In addition to its planning activities, the Division of Health and Welfare conducts its operations through the Public Health Service, Office of Education, Social Security Board, Recreation Section, and Social Protection Section.

The Division on Nutrition is under the direction of Milburn L. Wilson, Assistant Director, and William H. Sebrell, M.D., Deputy Assistant Director. The major activities of the Nutrition Division, which works with the National Nutrition Advisory Committee, the subcommittees on Food and Nutrition and on Food Habits of the

and Its Relationship to Some Other Agencies*

F. Sullivan 2,10,62

National Research Council, and the State Nutrition Committees are the organization and conduct of a nation-wide campaign for the improvement of nutritional standards and food habits.

The Health and Medical Committee was established, with the approval of the President, by the Council of National Defense, September 19, 1940. This committee consisted of Dr. Irvin Abell, chairman; the Surgeon General of the Army (Major General James C. Magee); the Surgeon General of the Navy (Rear Admiral Ross T. McIntire); the Surgeon General of the U. S. Public Health Service (Dr. Thomas Parran), and the chairman of the Division of Medical Sciences of the National Research Council (Dr. Lewis H. Weed). The original order establishing the Health and Medical Committee stated:

It will be the responsibility of the committee to advise the Council of National Defense regarding the health and medical activities affecting national defense. In carrying out its functions, the committee may (a)

utilize, to the extent that such facilities are available for such purpose, the laboratories, equipment and services of the Medical Departments of the Army and Navy, of the Public Health Service, and of other government institutions; and (b) within the limits of the appropriations allocated to it, to contract with and transfer funds to such institutions, and to enter into contracts and agreements with individuals or educational or scientific institutions for studies, experimental investigations and reports.

Subcommittees were appointed in these fields: Medical Education, Dentistry, Hospitals, Industrial Medicine, Negro Health, Rehabilitation, and Nursing. These committees gave their attention chiefly to issues of medical and nursing personnel, some of the medical problems of Selective Service, and to many research problems. When the Health and Medical Committee became part of the Office of Defense Health and Welfare Services, created on September 3, 1941, its research functions were transferred to the Office of Scientific Research and Development. Dr. A. N. Richards, Chairman of the Committee

on Medical Research of the Office of Scientific Research and Development, also serves on the Health and Medical Committee of the Office of Defense Health and Welfare Services. Dr. James A. Crabtree, Surgeon, U. S. Public Health Service, is its Executive Secretary.

The Procurement and Assignment Service was established November 1, 1941, to coördinate the various demands on the nation's medical, dental, and veterinary personnel to assure their most efficient utilization. The plans for the service are designed to meet both military and civilian needs. Its detailed functions are:

1. To receive from various governmental and other agencies requests for medical, dental, and veterinary personnel.
2. To secure and maintain lists of professional personnel available, showing detailed qualifications of such personnel.
3. To utilize all suitable means to stimulate voluntary enrollment, having due regard for the over-all public health needs of the nation, including those of governmental agencies and civilian institutions.

The Section on Social Protection, in coöperation with existing state and local agencies, is responsible for safeguarding the armed forces and civilian population from the various hazards of commercialized vice. One of its major concerns is the control of venereal diseases in the armed forces by the suppression of prostitution in the extra-cantonment zones.

Closely related to the work of the Section on Social Protection is that of the Section on Recreation which is responsible for stimulating and coördinating recreational programs in communities adjacent to army, navy, and war-industrial establishments, and assisting such communities to secure supplementary recreational facilities.

OFFICE OF CIVILIAN DEFENSE

The Office of Civilian Defense was established May 20, 1941, by Executive

Order within the Office for Emergency Management. James M. Landis succeeds Fiorello H. LaGuardia as Director. The original order was amended by subsequent Executive orders: (1) enlarging the Volunteer Participation Committee; (2) including the American Red Cross among the organizations to be represented on the Board for Civilian Protection.

"The functions of the OCD as defined by Executive Order are to:

- "Coördinate Federal Civilian Defense activities which involve relationships between the Federal Government and State and local governments;
- "Study and deal with problems which arise from the impact of the industrial and military defense effort upon local communities;
- "Assist State and local governments in the establishment of State and local councils or other agencies designed to coördinate civilian defense activities;
- "With the aid of the Board for Civilian Protection, plan and carry out civilian defense programs for the protection of life and property in the event of emergency, including the recruitment of and training of civilian auxiliaries;
- "With the aid of the Volunteer Participation Committee, promote activities designed to sustain the national morale and to provide opportunities for constructive civilian participation in the defense program;
- "Review existing or proposed measures affecting State and local defense and recommend such additional measures as may be necessary or desirable to secure adequate civilian defense.

"The Board for Civilian Protection, whose members serve as such without compensation and advise and assist the OCD Director in the formulation of civil defense programs, is made of representatives of the War Department, the Navy Department, the Department of Justice, the Federal Security Agency, the American Red Cross, the Council of State Governments, the American Municipal Association, the United States Conference of Mayors, and the Volunteer Participation Committee.

"Upon the recommendations of the Board, an Administrative order was issued establishing Regional Civilian Defense Areas and Regional Offices of the Office of Civilian

Defense coincident with the Army Corps Areas. The Division of State and Local Coöperation, previously established as an instrumentality of the National Defense Advisory Commission, was absorbed by the OCD.

"The Volunteer Participation Committee, representative of the various regions and interests of the Nation, was created by the President on July 19, 1941. It comprises 45 members who serve without compensation.

"The Committee as a whole acts in an advisory capacity to the Director of the OCD. Its members, in groups of five, function in a similar capacity as advisors to each of the nine directors of the OCD."*

The Medical Division of the Office of Civilian Defense, of which George Baehr, M.D., is the Chief Medical Officer, has a Medical Advisory Board and maintains a close relationship with the American Red Cross which has been the chief agency in meeting needs arising from catastrophes, both military and natural, for half a century. There are five groups of activities within the division. These are Emergency Medical Services and First Aid, Physical Rehabilitation, Nursing, Sanitation and Public Health Engineering, and Information Service. The Information Service has two branches—one operating officially and the other through the American Medical Association.

The Medical Division has issued two bulletins for the guidance of local Defense Councils, one July 1, 1941, entitled *Emergency Medical Service for Civilian Defense*, and a supplement in November, entitled *Equipment and Operation of Emergency Field Units*. These bulletins provide specific, detailed recommendations for local organizations. One of them summarizes the division's function thus:

The Medical Division is charged with the preparation of plans for emergency medical service and equipment. . . . Because of geographical and administrative diversity in various parts of the country, general plans

are presented as recommendations to state and local defense councils for adaptation to meet the needs of the different areas. The general adoption of a common pattern in organization and equipment for civilian defense is highly desirable so that adjacent communities may pool or exchange emergency resources in time of need.

Interrelationships: ODHWS, OCD, ARC, Children's Bureau—With so many new names and unfamiliar labels, it might appear that disorganized expansion with dislocation of essential services is taking place in public health administration. Such is not the case. Liaison officers from various groups are assigned to serve as consultants on planning committees in related agencies. The value of this policy is indicated by work being done toward definition of functions, by relinquishing certain pursuits to other groups with machinery already geared for action, and by the formation of new groupings when indicated.

For example, the Day Care Programs for Children are made possible by the recent appropriation of \$150,000,000 for "Community Facilities" in defense areas. These projects must be certified by the Children's Bureau and by the Office of Education. State welfare departments will be responsible for their supervision. State and local health departments will in many areas have the responsibility of providing medical supervision and medical service in day-care centers. Volunteers, enlisted through local defense councils, and trained in some cases by personnel from constituent agencies of the Federal Security Agency which carries out much of the program of the Office of Defense Health and Welfare Services, will be essential for their functioning. The American Red Cross also will, in many localities, have much to contribute to this and many other joint programs.

A further example of the ironing out of possible duplication of effort is in the work being done in blood procurement. This job is now being continued

* Office of Emergency Management Handbook, November, 1941.

exclusively by the American Red Cross. It might well have become a function of the Medical Division of the Office of Civilian Defense, but the fact that the Red Cross does the work because it was already equipped to take the responsibility indicates the values realized by conference and joint planning.

This procedure of delineation of functions has been going on not only incidentally through personal contact, but also in the formulation of carefully thought out statements of policy governing the relationships of the various agencies. In *Victory*, February 3, 1942, appeared the following from a joint agreement reached by the USOCD, ODHWS, and ARC:

The Red Cross, through its Chairman as a member of the Civilian Protection Board, has made available all of its services as needed by the U. S. Office of Civilian Defense and State and Local Defense Councils. As illustrative of its national services, attention is called to the programs involving blood plasma, medical technologists and nursing enrollment. The Office of Civilian Defense and the American Red Cross are agreed that Defense Councils and Red Cross Chapters should develop local plans of coöperation in their civilian defense activities.

Recognizing the basic responsibility of government it is the duty of every Red Cross Chapter and Branch to aid in the most efficient marshalling of the community's resources. It is agreed that duplication should be avoided in these services and training courses required in civilian defense activities and that the long-established nation-wide program of the Red Cross should be utilized to the fullest extent.

That there will be no uniformity of local development or of utilization to the fullest of existing resources goes without saying. In some communities a good job is being done; in others there is lagging. Some communities had ready for use most of the things needed for disaster relief, just as they had smoothly

functioning educational systems and public health organizations. Their job of doing things as well as reaching agreements on what to do and how to do it will be infinitely easier than in those where facilities are not very far along and where experience in coördination is brief. In those communities where the need is acute, both because of emergencies and of underdevelopment, there are special federal services available as well as those of the Red Cross and of other semiofficial and non-official agencies.

Examination of the efforts and achievements made thus far to meet public health needs of the nation at war leaves the impression that there is ample justification for encouragement. Rapid changes involving many phases of complex problems cannot be made without some apparent confusion. But acceleration in the coördination of the social and economic factors with the more obvious medical and engineering aspects of public health far more than compensates for the extra effort that is required in making the necessary shifts.

A joint statement issued May 18, 1942, by the USOCD and ARC supersedes previous ones. With regard to emergency medical services, it states:

"During bombing or other enemy attack, all services are directed from the Control Centers in charge of the Commander of the Citizens' Defense Corps. Responsibility for the care of those injured as a result of enemy action rests with the Emergency Medical Service of the Citizens' Defense Corps under the direction of the Chief of the Emergency Medical Service. . . . During the emergency period, ambulances and motor units assigned to such transportation service will be under the direction of the Chief of Emergency Medical Service or the Transport Officer. . . ."

"After the emergency period the appropriate public agencies are expected to undertake the care of civilians in accordance with plans developed in conjunction with the Office of Defense Health and Welfare Services and the Federal Security Administrator. Funds will be made available for this purpose by the Federal Government through the Federal Security Administrator."

Integrating Mental Hygiene in County-wide Health Service

VICTOR H. VOGEL, M.D.

*Assistant Chief, Division of Mental Hygiene, U. S. Public Health Service,
Washington, D. C.*

IN considering the services available to the psychopathic case, the following letter is interesting:

“Dept. of Health
Washington, D. C.

Dear Sirs:

My army examination revealed that I had this defect: constitutional psychopathic inferior. In order to treat this, I would like to know just what it means, and all other details that you can give regarding it will be very much appreciated.
I thank you very much.”

The boy who wrote this letter lives in a town of about 10,000 population, so there is slight chance of there being either a mental hygiene clinic or a private psychiatrist to whom he could go for advice in this very disturbing situation which has arisen in his life. Even if he lived in a city of 50,000 to 100,000 the chances would be two-to-one against there being a mental hygiene clinic available to him. In about three-fourths of the cities over 100,000 such a person could obtain help, but if he lived in a rural or semi-rural community it would have to be one of very few for mental hygiene assistance to be available to him. In 15 entire states he could obtain no such assistance.

Neuropsychiatric conditions have been responsible for about 7 per cent of all Selective Service rejections (63,000 men up to May 1 of this year). The great

majority of these rejected men of necessity have gone back to home and community without being referred to any psychiatric or mental hygiene agency which could at least give an explanation and reassurance in the crisis even if unable to do any preventive or curative work. The emotional harm which accompanies rejection by the induction boards of individuals who have already bidden their families and friends goodbye and quit their jobs is very considerable. This situation is doubly unfortunate in the case of persons with previous emotional difficulties who may have been making a rather precarious adjustment anyway.

The total amount of mental hygiene service available to the country is inadequate enough but the fact that only 20 per cent of such services are in small communities, which include 75 per cent of the population, makes it impossible for many individuals with nervous and emotional problems to obtain help. Venereal and other diseases coming to the attention of public health authorities from both Selective Service and other sources are often being referred for appropriate treatment, and a rehabilitation program is being planned for defects which occur in selectees. But these plans cannot include much attention for nervous and mental disorders with existing facilities.

Why has not better provision been made for the type of illness which is responsible for half of all disability? It

* Read before the Southern Branch American Public Health Association at the Tenth Annual Meeting in St. Louis, Mo., November 11, 1941.

is largely due to the fact that the development of mental hygiene service has been left to voluntary and non-health governmental agencies where development to an adequate level has been illogical and difficult. Illogical because mental and emotional illnesses are primarily matters of public health medicine closely bound up with so-called physical or organic conditions which have been accepted as health problems. Difficult because of the scarcity of trained specialists needed and the fact that most communities are not large enough to support a full-time mental hygiene clinic, and no higher agency has undertaken to organize part-time service to groups of communities. Unreasonable stigma and prejudice rooted in past superstitions attached to mental illnesses have contributed to the indifference of the public in general and of physicians concerning mental hygiene.

It is usually at the county level where public health services meet the public. The establishment of mental hygiene work as one of the county health services (except of course in those areas where the population is concentrated into larger cities) should be the object of mental hygiene plans whether the planning is done at a state or national level. The county health department is established in the community with close relations with the school and welfare agencies, private medical practitioners, and parents, the most important sources which will send requests for mental hygiene consultation. People will come and bring their children with confidence and hope to the same health center where they have obtained other health services.

Only counties with a population of 100,000 to 150,000 need full-time mental hygiene units. Smaller counties should each have the services of a mental hygiene clinic one day a week for each 20,000 to 25,000 population.

The usual mental hygiene unit con-

sists of one psychiatrist, one psychologist, two psychiatric social workers, and one clerk. Such a group, because it is small and needs no heavy or bulky equipment, is readily mobile, requiring only one ordinary automobile for transportation. Nurses attached to health units if they have adequate training in psychiatric social work can take the place of traveling social workers. The responsibility for organizing part-time traveling service to counties belongs in most states to the state health department.

Some idea of the magnitude of the mental health problem and the types of cases encountered is shown in Table 1. The data from these two communities, one an urban area and one a rural county, each with approximately the same proportion of Negroes, show a close agreement in the total figures for mental health problems, although the classification system used differs somewhat. Both studies give an incidence rate for mental health problems of approximately 7 per cent. Not all of these will come to the mental hygiene clinic for attention, since some are already receiving care; most of the psychotics will be in state hospitals, many of the defectives will be in state schools, and some of the delinquents will be in penal institutions. Others will not seek or accept help.

About 25 per cent of the psychotics, according to experience in the Eastern Health District,¹ still will be in the community, and this is not necessarily a bad condition if they are under the care of a mental hygiene clinic, which may be able to prevent their commitment, or their recommitment in the case of parolees from the state institutions. In a recent analysis of 100 cases of recovered schizophrenia, Dr. Thomas Rennie wrote: "The most striking single factor for recovery seems to be a long term contact with a physician or a clinic. These patients are capable of

accepting guidance and of resolving personal conflicts with the help of the psychiatrist." ² It has been estimated that as high as 20 per cent of the patients in state hospitals without social service or outpatient follow-up could be paroled if some psychiatric or mental hygiene agency existed in the community to supervise them.³ Parole supervision is a very helpful and economical co-operative enterprise with state hospitals.

The mental hygiene clinic should take the place of the courtroom and the jail in the treatment of some alcoholics. Austin H. MacCormick at a recent meeting of the Research Council on the Problems of Alcohol said: "As soon as possible the care and treatment of alcoholics should be taken from our penal and correctional systems and turned over to state and local departments of

health or hospitals, depending on the particular situation in any jurisdiction. Only when alcoholism is treated as a problem of public health and mental hygiene, rather than of law and penology, and the alcoholic considered a sick person in need of treatment, rather than an offender in need of punishment, will we put an end to our present record of almost complete failure."⁴ The courts have many cases besides alcoholics for whom they would appreciate psychiatric consultation.

The schools and welfare agencies will refer most cases which come to the mental health clinic. Children referred offer the best opportunity for preventive psychiatry, but psychiatric consultation for adults referred by welfare agencies, for example, may result in whole families going off relief. Most counties have no

psychiatrists in private practice. General physicians sincerely appreciate the help they can obtain by referring what they consider the most undesirable element among their patients to the mental hygiene clinic. Recent literature contains numerous estimates as to the proportion of patients coming to the general practitioner who have an important emotional component. The most recent figures seen come from a London survey⁵ which found that the psychic factor was important in the illnesses of 80 per cent of all hospital admissions, and that in any group of sick people something like 30 per cent are suffering from conditions for which it would be helpful to have psychiatric advice.

Each case referred to the mental hygiene clinic gives opportunity for more palatable instructions in mental hygiene principles than is possible by more formal methods; this educational work is probably the most valuable long-range part of the mental hygiene effort.

An outline showing the most important aspects, both clinical and educational, of a county health department mental hygiene program appears as Table 2. This is taken from the Williamson County, Tenn., mental hygiene program which has been functioning about 6 years. For the first 5 years it was carried on as a survey program from which several interesting papers have come. In the latter part of 1940 it was reorganized with the emphasis on community service looking forward to its extension to other areas of the state.

Clara Bassett, the author of *Mental Hygiene in the Community*, in an unpublished paper entitled "Mental Hygiene Possibilities in a County Health Department," stresses the importance of a thorough community survey prior to the establishment of clinical service, and gives a very fine outline to be followed in such a study. A sufficient number of surveys in different types of communities have probably been done now

TABLE 2

Outline of a County Mental Health Program, Williamson County, Tenn.

1. A psychiatric and mental hygiene clinic, serving the county.
2. A special program of training in psychiatry and mental hygiene for the regular public health personnel of the county, including:
 - a. A short didactic course in the fundamentals of psychiatry
 - b. Demonstration of patients at weekly staff conferences on clinic cases
 - c. Routine individual and group conferences of public health nurses with a case work supervisor
 - d. Joint visiting in the field by public health and psychiatric personnel
3. Psychiatric education of other professional groups:
 - a. Practising physicians of the community
 - b. School teachers of the county
4. Community education through:
 - a. Talks to Parent Teacher Associations and similar groups
 - b. Newspaper articles
 - c. Distribution of literature
 - d. Radio talks
 - e. Films

(Eastern Health District,^{1, 6, 7} Williamson County, Tenn.,^{8, 9} Kentucky,¹⁰ Chicago¹¹) to make an elaborate survey unnecessary prior to starting every new county mental hygiene program. Both Miss Bassett and Dr. Roth from the Tennessee study point out, however, that surveys do more than prove the existence of a large number of cases which need help; this can now be taken for granted. They also serve to familiarize the mental hygienist with the various community leaders and agencies which will both contribute cases to the mental hygiene program and act as social and economic resources which are so important in the successful operation of the mental hygiene service.

An increasing proportion of referrals to the clinic will come from the other health department personnel after they become familiar with the help available and sensitized to recognizing cases that need such help. The public health

nurses and physicians have intimate contact with a group of people who have more than their share of the disturbing situations and emotional crises which make mental hygiene problems. The nurse who actually gets into the home frequently sees family situations which need help and, indeed, she often gives valuable help to the best of her ability, although she would likely call it common sense sympathy and understanding rather than mental hygiene.

The admirable book *The Public Health Nurse and Her Patient*, by Ruth Gilbert,¹² should be read by every health officer and nurse, and will be particularly valuable if supplemented by appropriate educational efforts of the mental hygiene psychiatrist attached to the health department. The public health physician who sees the newly identified cases of syphilis and tuberculosis frequently is aware of important mental health problems which should be referred to the mental hygiene clinic. Attendance at prenatal clinics by the psychiatrist gives an opportunity for important preventive work with expectant mothers whose emotional needs are often ignored.

A psychiatrist who attends the well child clinics has an opportunity to do real preventive psychiatry in the truest sense of the term, seeing cases of faulty habit behavior and emotional patterns before they have been recognized as problems. Such clinics are held with encouraging results in the Eastern Health District of Baltimore.¹³ It has been suggested that these clinics be held in the domestic science classroom of the high schools with the assistance and under the observation of girls who will be tomorrow's mothers.

Much more could be added concerning the clinic phase of the mental hygiene program but it suffices to say that case work should be the backbone of the program. In a community containing so many persons urgently in need

of help, a purely educational program falls flat.

I am reminded of the challenge of the child's charade game,

"Here we come."

"Where from?"

"What's your trade?"

"Show us some."

Mental hygiene psychiatrists must also "show us some." Teaching and preaching without performance are not likely to acquire the interest and support required for the success of the program.

Clara Bassett stresses the importance of directing the first educational work toward public health personnel which is also mentioned first in the educational aims of the Williamson County program, where it starts with a course of six didactic evening sessions supplemented by recommended reading. Dr. Roth reports that this is well accepted and is considered to be a stimulating experience by those taking the course. These lectures are followed by group conferences every 2 weeks at which cases are presented. Some psychiatric training for health department personnel is particularly helpful in the increasing number of states in which health officers are given legal responsibility in the commitment and sterilization of the mentally ill.

Weekly individual conferences are held with the nurses in which a professional member of the mental hygiene unit discusses, from a mental hygiene aspect, individual cases in the nurse's load. Suggestions are given as to management and the progress of cases is followed from week to week. Frequently the consultant actually visits the homes with the nurses.

Case consultations have already been mentioned as the most important means of educating practising physicians, most of whom will have graduated from schools with inadequate psychiatric instruction. Talks and papers to medical

groups however are also, of course, in order. These remarks apply also to educational work with the school teachers. In Alabama several state health department mental hygiene clinics are actually being held in teachers' colleges.

Talks to Parent Teacher Associations and other lay groups must be made whether or not one is convinced of their value. Care should be taken however not to expend a disproportionately large amount of time in this activity; time spent in seeing and helping troubled individuals from the community will do more toward creating confidence and good will for the program. The laity should be encouraged to form mental hygiene groups to affiliate with the state and national mental hygiene society through which literature and speakers for programs may be obtained. The National Committee for Mental Hygiene is also a source of literature which may be distributed free, or at a slight cost, and also material for newspaper articles. One state health department is putting not only pamphlet literature but a limited number of mental hygiene books in the public libraries, particularly in the rural traveling libraries.

The collection of epidemiological data in connection with mental disorders is being increasingly recognized as valuable; for this reason close collaboration should exist among the departments of mental hygiene, epidemiology, and statistics. Interesting and perhaps important correlations have been found whenever social, economic, and mental disorder interrelationships have been studied.^{1, 6, 7, 8, 9, 10} There is a great need for a central register of nervous and mental disorders. This should properly be established in the state health department, but it depends on material gathered and submitted by the counties.

In closing, I wish to mention the fine address given by Sir Wilson Jameson, Chief Medical Officer of the British Ministry of Health at the American

Public Health Association Meeting in Atlantic City.¹⁴ In this address, which for the most part took the form of a report on public health conditions in England, Sir Wilson devoted a generous proportion of his time to nervous and mental disorders. It is apparent that even in England, a country at war and beset by so many emergency public health problems, mental hygiene is considered an important phase of the public health. It is important as a trend in public health thinking in our country that the Southern Branch of the American Public Health Association has placed this subject on its annual program.

Experience with the Test for Vi Agglutinative Properties for *Eberthella typhosa*

MARION B. COLEMAN, F.A.P.H.A.

*Division of Laboratories and Research, New York State
Department of Health, Albany, N. Y.*

THE study of Vi agglutination¹ with *Eberthella typhosa* was undertaken with the twofold objective of securing experience with the technical procedures and determining the practicability of performing the test as a routine procedure in a diagnostic laboratory. Vi agglutination has been found of limited value in the diagnosis of typhoid fever, since it does not occur consistently at any one stage of the illness.²⁻⁹ On the other hand, it has been demonstrated in sera from a high percentage of typhoid carriers.¹⁰⁻¹⁴ Most of these reports are based on reactions with a pure Vi strain of *E. typhosa*, designated by Bhatnagar¹² as "Vi 1," or with a strain rich in Vi antigen after absorption of the serum with a strain devoid of Vi antigen. No mention was found in the literature of a zone of inhibition (pre-zone, prozone, or proagglutinoid zone) in the tests, a phenomenon that was at once apparent when our work was undertaken. Centrifugation proved effective in demonstrating reactions in high concentrations of sera, not only of those shown to have zones of inhibition, but in many in which no agglutination was observed prior to this treatment. Later, it was found that Shibley (1929)¹⁵ had made a similar observation in his study of artificially produced zones of inhibition.

TECHNIC

A pure Vi strain of *E. typhosa*, designated by Bhatnagar as "Vi 1," and the "Watson" strain, known to be rich in Vi antigen, were obtained from Dr. Kauffmann, State Serum Institute, Copenhagen, Denmark. They were maintained on inspissated egg medium,^{16, 17} in sealed tubes and stored in a refrigerator.

INSPISSATED EGG MEDIUM¹⁷

Sodium chloride solution, 0.5 per cent.. 1 part
Eggs (white and yolk)..... 3 parts

Transfer the egg contents aseptically to a weighed sterile flask containing glass beads. Determine the increase in weight and add the required amount of sterile salt solution. Mix by shaking thoroughly. Dispense aseptically 3 ml. in 125 x 13 mm. tubes. Slant and inspissate at 80° C. for 1 hour on two successive days.

Transplants were made at 6 month intervals. Subcultures on beef infusion agar were incubated from 18 to 20 hours at from 35° to 37° C. and suspended in 0.85 per cent salt solution. Living suspension was prepared each day that tests were performed. Suspension killed by the addition of 0.2 per cent formalin (40 per cent formaldehyde) was stored in a refrigerator and used for no longer than 4 weeks after preparation. The turbidity of suspensions was adjusted to that of barium sulfate standard No. 3.¹⁸ Equal volumes (0.3 ml.) of suspen-

sion and 5-, 10-, 20-, and 40-fold dilutions of sera were combined in 11 x 75 mm. tubes, incubated for 2 hours at from 35° to 37° C., and left in a refrigerator overnight. The reactions were recorded before and after centrifugation for 10 minutes at approximately 2,000 r.p.m.

The degree of agglutination was recorded as follows:

A. Before centrifugation—

- 4+ supernatant clear; complete agglutination
- 3+ supernatant clear or nearly clear; definite clumping
- 2+ supernatant slightly turbid; definite clumping
- + supernatant turbid; small clumps definitely visible to unaided eye
- uniformly turbid suspension; no clumps

B. After centrifugation—all reactions read after shaking.

Comparison with the suspension combined with salt solution for purposes of control is very important.

- 4+ complete agglutination in clear fluid
- 3+ definite agglutination in clear or nearly clear fluid
- 2+ definite agglutination in slightly turbid fluid
- + clumps definitely visible to the unaided eye in turbid fluid
- no clumps; uniformly turbid suspension

Serum for purposes of control was produced in rabbits with *E. typhosa* Vi 1. The titer was relatively low.

After absorption with *E. typhosa* "Felix H 901," a strain devoid of Vi antigen, no agglutination was obtained with the latter in a 10-fold or greater dilution, while the Vi 1 strain was agglutinated in an 80- or 160-fold dilution. A high titered agglutinating serum that contained no Vi agglutinative properties was also used for purposes of control.

Absorption of agglutinative properties other than Vi was undertaken with a small number of sera. A heavy suspension of the growth of *E. typhosa* Felix H 901 from beef infusion agar was made in a 5-fold dilution of serum. This was incubated 2 hours at from 35° to 37°C. and left at room temperature overnight. It was then centrifuged until the supernatant was clear—usually for 30 minutes at approximately 2,000 r.p.m. The supernatant, undiluted and in 2-, 4-, and 8-fold dilutions, was tested for agglutination with *E. typhosa* Felix H 901 and Vi 1, and usually with the Watson strain.

DISCUSSION

The results summarized in Table 1 were obtained after centrifugation of tests with living suspension of *E. typhosa* Vi 1. All sera were tested at least twice, except a few that reacted in high dilutions in the first examination. The relatively large number of

TABLE 1

Reactions in Sera Following Centrifugation of Tests with Living Suspension of *E. typhosa* Vi 1

Source of Specimen	Number Tested	Definite Agglutination		No Agglutination		Irregular or Indefinite Agglutination	
		No.	Per cent	No.	Per cent	No.	Per cent
Typhoid carriers	82	62	75.6	8	9.7	12	14.6
Patients having typhoid fever	37	14	37.8	12	32.4	11	29.7
Patients having infections with members of the paratyphoid-enteritidis (<i>Salmonella</i>) group	12	1	8.3	8	66.6	3	25.0
Individuals who had received typhoid vaccine	46	7	15.2	34	73.9	5	10.8
Random specimens*	157	8	5.1	130	82.8	19	12.1

* From the information available, these specimens could not be placed in any of the other four groups.

indefinite or irregular reactions should not be misinterpreted. They usually represent no agglutination in one test and definite but incomplete agglutination (2+) in a 10-fold dilution of the serum in another test, which is no greater variation than may be expected in repeated examinations of this type. Agglutination was apparent only after centrifugation of the tests with half of the 92 sera that gave reactions.

them, as well as in the artificially produced Vi agglutinating serum. Thus, it seems important that tests for Vi agglutination be performed at least twice, preferably with not less than 3 or 4 days intervening. The results with two sera, one from a patient having typhoid fever and the other from a carrier, have been summarized in Table 2 to illustrate this point.

Since some species of *Salmonella*

4+ = complete agglutination

3+, 2+, and + = degree of agglutination as compared with 4+

- = no agglutination

Approximately one-third of the sera were tested with formalin-treated as well as with living suspension of *E. typhosa* Vi 1. The former was agglutinated somewhat more frequently before centrifugation, but the titer after centrifugation was often higher with living suspension.

Not infrequently, sera that reacted only after centrifugation when first tested, gave agglutination before as well as after this treatment in tests performed one or more days later. Occasionally, little or no agglutination occurred before or after centrifugation of tests with fresh sera, and definite reactions occurred in later tests. These irregularities cannot be explained by variation in the agglutinability of the living culture, since usually several sera were tested at the same time and agglutination was obtained in some of

possess Vi antigen, it is not surprising that serum from one patient having an infection with a member of group D *Salmonella* gave definite Vi agglutination with *E. typhosa* in an 80-fold dilution. Blood from three other individuals having infections with the same species failed to show any Vi agglutinative properties, while that from a fifth reacted irregularly.

The relatively large number (15 per cent) of reactions in sera from individuals who had received typhoid vaccine may be more apparent than real, because many such specimens that failed to agglutinate were tested only once, and therefore are not included. One of the seven individuals who had received typhoid vaccine and whose sera contained Vi agglutinative properties was a nurse who was caring for her brother, who had typhoid fever.

No *E. typhosa* was found in several fecal specimens from her; no specimens were submitted from the others.

Sufficient information is not available concerning the specimens selected at random to draw definite conclusions as to the significance of the Vi agglutinative properties in eight, or 5 per cent, of the number examined. All except one contained granular or floccular agglutinative properties or both. One fecal specimen only was received from each of two of these individuals, and none from the others. One was said to have had her gall bladder drained, but so far as could be determined, a bacteriologic examination of the bile or of feces had not been undertaken.

The presence of Vi agglutination was not correlated with floccular and granular agglutination. Of the eighty-two sera from carriers, eighty gave floccular agglutination in at least a 40-fold dilution and two, in only a 20-fold dilution. Vi agglutination occurred in one of the latter. Of the other seven in which no Vi agglutinative properties were demonstrated, one gave floccular agglutination in a 640-fold dilution, five in a 160-fold dilution, and one in an 80-fold dilution. Several sera from patients having typhoid fever contained no Vi agglutinative properties, but gave both granular and floccular agglutination with *E. typhosa* in relatively high dilutions.

Forty-five sera absorbed with *E. typhosa* Felix H 901 were tested for agglutination with *E. typhosa* Vi 1, and most of them with the Watson strain as well. Centrifugation was often necessary to demonstrate agglutination after, as well as before, absorption. There was no appreciable difference in titer with *E. typhosa* Vi 1 in unabsorbed and absorbed portions of sera. The titer with *E. typhosa* Watson in absorbed sera was usually the same as, but in a few instances lower than that with Vi 1. This procedure was not studied further,

because it seemed to offer no advantage over the simpler agglutination test.

SUMMARY

The observations reported are based on the demonstration of agglutination with the strain of *E. typhosa* designated as Vi 1 by Bhatnagar. Vi agglutination was often demonstrated only after centrifugation, especially in tests with fresh sera. If these sera were retested after a few days, agglutination was sometimes observed before the tests were centrifuged. These facts may be of significance in other agglutination tests, especially in sera with zones of inhibition.

In a study of over 300 sera, definite Vi agglutination was obtained in 75 per cent from known typhoid carriers; 37 per cent from patients having typhoid fever; 15 per cent from individuals to whom typhoid vaccine had been administered; and 5 per cent of sera selected at random. Insufficient data are available to establish the significance of the reactions in the "random" specimens, and in those from persons who had received typhoid vaccine.

The demonstration of Vi agglutination with *E. typhosa* suggests infection with this microorganism and warrants thorough investigation. Absence of Vi agglutination does not exclude such a condition. The performance of this test as a routine diagnostic procedure seems practicable in any laboratory where facilities are available for adequately controlling the reactions of the agglutinating suspension and the sera.

Important News

In response to numerous inquiries, the Program Committee announces that plans are proceeding to hold the 71st Annual Meeting of the Association in St. Louis, October 27-30 as planned.

Public health is sufficiently identified with the war effort to make it imperative that the profession should hold its regular session, to which will come many members of the armed forces of the United Nations and many leaders in war industry to share the latest information available both here and abroad for our common purpose. There will be representation from England, where recent experience shows that it is essential that public health groups meet—not in spite of the emergency, but because of it, and because they are so integral a part of defense.

As Dr. Parran has so well said, "Ours is the responsibility for leading the fight against the weakness from within which impedes attack upon the enemy without."

The U. S. Public Health Service Restaurant Sanitation Program*

A. W. FUCHS, C.E., F.A.P.H.A.

Senior Sanitary Engineer, U. S. Public Health Service, Washington, D. C.

ACCORDING to the Public Health Service compilation of disease outbreaks conveyed through various vehicles in 1939, the number of outbreaks reported by state and city health departments from foods other than milk was greater than for all other vehicles combined. Water supplies were responsible for 43 outbreaks, milk and milk products for 41, other foods for 148, and unidentified vehicles for 17. Of the 148 food-borne outbreaks, 88 involved food poisoning, 37 gastroenteritis and dysentery, 9 botulism, 5 typhoid fever, 4 trichinosis, 2 paratyphoid fever, 1 scarlet fever, and for the remaining 2 the disease was not given.

Of the 47 food-borne outbreaks for which the type of establishment was reported, all but 4 were traced to establishments regularly serving public or semi-public meals, including restaurants, clubs, hotels, camps, schools, and public institutions. The number of public eating and drinking establishments responsible for outbreaks cannot be definitely determined from these reports, but there is every indication that it is significant, and that greater attention to restaurant sanitation is warranted.

While it is impossible to estimate the amount of disease actually spread through public eating and drinking establishments, there is no doubt that food and utensils may be infected by

organisms from the saliva and other body discharges. The organisms may be transmitted by direct or indirect contact from a case or carrier among the customers or the employees. They may be coughed or sneezed on food, dishes, or utensils. They may be left on glasses, cups, spoons, and forks by mouthing. They may reach the dishwater from washers or indirectly from customers. Or cleaned dishes may be exposed to contamination by handling or droplet infection.

DEVELOPMENT OF RECOMMENDED ORDINANCE AND CODE

The Public Health Service first became actively interested in the sanitation of eating and drinking establishments in 1934. In that year minimum restaurant sanitation regulations were proposed for approval by the National Recovery Administrator in connection with Section IV, Article VIII, of the *Code of Fair Competition for the Restaurant Industry*.

Next, at the request of some health officers for a suggested form of ordinance for local use, the Public Health Service prepared the December, 1935, draft of *An Ordinance Regulating Food and Drink Establishments*. This draft was mimeographed but was not circulated except on request.

As a result of successful experience with the *Standard Milk Ordinance*, an increasing demand arose on the part of health officers for an ordinance and interpretative code on restaurant sanita-

* Read at a Joint Session of Engineering and Food and Nutrition Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 15, 1941.

tion. Accordingly, after a detailed study of 18 existing municipal ordinances and state regulations, a tentative *Ordinance and Code Regulating Eating and Drinking Establishments* was issued in mimeographed form in March, 1938. In spite of its tentative nature there were many requests for copies, and it was adopted as a local ordinance or as state regulations in many areas.

It was not until 1940 that the Public Health Service Sanitation Advisory Board had an opportunity to review the tentative edition and consider proposed amendments. Following this meeting the first non-tentative edition of the recommended *Ordinance and Code Regulating Eating and Drinking Establishments* was issued in mimeographed form in June, 1940.

The latest edition is, therefore, the culmination of six years' effort represented by four different drafts. It embodies the best information at present available on restaurant sanitation but, like the other codes recommended by the Public Health Service, it should be considered subject to change as improvements are developed through research and experience. It is recommended for voluntary adoption by states, counties, health districts, and municipalities in order to encourage a greater uniformity and a higher level of excellence in the sanitary control of eating and drinking establishments. This edition has been incorporated in both the 1940 and the 1941 editions of the *Sanitation Code* suggested by the Public Health Service for state or local adoption in national defense areas.

Inspection forms were prepared to accompany both the 1938 and the 1940 editions. The printed 1940 inspection form is available for quantity purchases by health officers from the Superintendent of Documents. It is planned to print office ledger record forms for posting inspection and laboratory results, and sanitation rating forms for use by

the states in measuring the effectiveness of local control programs.

PHYSICAL EXAMINATION OF EMPLOYEES

Naturally, many diverse viewpoints had to be coordinated in drafting an ordinance that would be generally applicable. Among the questions at issue was whether to require physical examination of food handlers in restaurants. Such a requirement was included in the 1935 draft but has been deleted from both the 1938 and the 1940 editions. During its consideration of these *Codes* the Public Health Service Sanitation Advisory Board debated the advisability of including a provision for health examinations, but concluded that the conflicting opinions of health officers on the value of routine medical examinations for food handlers did not warrant such a requirement. For example, the experience of New York City as reported by Dr. Best in 1937¹ indicated that examinations made by private physicians were not considered reliable, and that the cost of adequate examinations by the health department was not commensurate with the public health benefits obtained. New York City has therefore discontinued annual examinations of food handlers.

Admitting that periodic examinations are unwarranted, it may be asked whether examinations made only before or at the time of employment are worth while in the case of food handlers. This is the procedure suggested in the current milk ordinance recommended by the Public Health Service, but even in that case examinations of milk handlers on farms producing milk for pasteurization is not recommended because of the large numbers involved. Employees of eating and drinking places are even more numerous, and the turnover is greater. The Advisory Board therefore concluded that even initial health examinations should not be required in a restaurant ordinance that is recommended for gen-

eral adoption. However, health officers who inquire are informed that they may include such a requirement at the time of adoption if they prefer to do so and if their official facilities for making examinations are adequate for the task.

Lest it be inferred that the recommended ordinance makes no provision for the control of communicable disease, attention is called to section 10, which makes the manager and the employee jointly responsible for the prompt reporting to the health officer of all cases of communicable disease, and to section 11, which authorizes the health officer to make adequate medical examinations of employees when infection is suspected, and to exclude infected employees from all eating and drinking establishments.

THE PROVISIONS OF THE ORDINANCE

The restaurant ordinance and code follows the same general form as the *Standard Milk Ordinance* which has had such wide acceptance. Part I is the short enabling form of the ordinance suggested for use wherever adoption by reference is considered legal. The short form greatly reduces the cost of publication, and is more readily kept up-to-date because it is so easily amended. Two short forms are presented, one a grading type, which permits enforcement by degrading or permit revocation or both, the other a non-grading type enforceable by permit revocation only. Part II is the unabridged ordinance recommended for adoption only where the short enabling form is not legal. All words referring to grading are enclosed in parentheses, so that the grading form of the unabridged ordinance is obtained by omitting the parenthesis signs only, while the non-grading form is obtained by deleting both the parentheses and the words included therein. Part III is the interpretative code, which gives the public health reason for each requirement of the ordinance and explains

in detail what constitutes satisfactory compliance.

A brief outline of the provisions of the recommended restaurant ordinance may be of value in this discussion.

Sections 1 and 2 deal with definitions and permits.

Section 3 requires the public display of a grade notice in all restaurants where the grading form of the ordinance is in effect. The grade display is the means whereby the competitive effect of grading tends to improve restaurant sanitation. Section 4 authorizes the examination and condemnation of unwholesome or adulterated food or drink.

Section 5 requires the inspection of all restaurants at least once every 6 months. A restaurant found violating any item of sanitation must be notified in writing and must be given a reasonable time to correct the defect. If the same violation is again found on the next inspection the restaurant is subject to degrading or suspension of permit.

Section 6, the longest and most important of the sections, lists the sanitation standards for grade A restaurants, which are identical with the minimum requirements where the non-grading form is adopted. These cover construction and cleanliness of floors, walls and ceilings, doors and windows, lighting and ventilation, toilet, water supply, hand-washing facilities, disposal of wastes, the construction, cleaning, bactericidal treatment, storage, and handling of containers and equipment, refrigeration of readily perishable foods, wholesomeness of food and drink, including milk, milk products, and shellfish from approved sources, storage and display of food and drink to avoid contamination, cleanliness of employees, and miscellaneous requirements. These items of sanitation are conveniently summarized in the inspection form prepared for use with this ordinance.

In the grading form of the *Ordinance*, the remainder of section 6 is concerned

with specifications for grade B, grade C, and itinerant restaurants. Grade B restaurants are those which fail to meet certain grade A requirements that are not of major public health significance. In communities which are not yet in position to limit operations to restaurants of the highest grade only, the grade B definition serves as the specifications for the second grade. In municipalities which under section 7 permit none but grade A restaurants to operate, except during temporary degrading periods, grade B serves a useful rôle as a penalty grade to which grade A restaurants may be temporarily degraded for minor violations which the health officer would hesitate to punish with so severe a penalty as suspension of permit.

Grade C restaurants are those which violate any of the requirements for grade B restaurants.

Itinerant restaurants (*i.e.*, those operating for temporary periods in connection with a fair, carnival, circus, public exhibition, or similar gathering) are required to comply with certain reasonable minimum requirements which are listed.

Section 7 provides that after 12 months following adoption, no restaurant may continue in business unless it complies with the minimum requirements, or (in case the grading form is in effect) unless it qualifies for grade A or grade B. Communities in position to do so may restrict operations to grade A restaurants only, except during temporary degrading periods not exceeding 30 days.

Section 8 outlines the procedure for reissuing of the permit or for regrading upward any restaurant whose permit has been suspended or which has been degraded.

Section 9 prohibits the use of any polish containing cyanide preparations for the cleansing or polishing of utensils.

Section 10 requires the restaurant manager to notify the health officer of

any communicable disease among his employees, and section 11 confers on the health officer broad powers of control when infection is suspected.

Section 12 specifies that enforcement shall be in accordance with interpretations contained in the *Code*. In section 13, on penalties, the exact wording is left to the community. The last two sections deal with the usual provisions regarding repeal, date of effect, and unconstitutionality.

EXTENT OF ADOPTION

The Public Health Service urges states not already doing so to launch a restaurant sanitation program along the same lines as the milk control program. A satisfactory state program would include the appointment of a restaurant sanitarian where necessary, promotion of the local adoption of the ordinance by municipalities, counties, and health districts, the training of local inspectors, provision for consultant service to local health departments on technical problems, and the measurement of the effectiveness of local control programs by means of sanitation ratings. The promulgation of this ordinance as state regulations may serve to encourage its local adoption by cities and counties within the state. Most states will prefer to delegate the enforcement of such state regulations to local health units where these are functioning.

In response to inquiries from many health officers, the Public Health Service recently circularized all state health departments to determine the extent of adoption of the recommended restaurant sanitation ordinance. Incomplete returns indicate that the ordinance or state regulations based thereon are legally in effect in communities located in 24 states and 1 territory.

In 6 of the states the State Board of Health regulations, based on or similar to the restaurant ordinance recommended by the Public Health Service,

are enforced state-wide; in 3 of these (Nevada, Oklahoma, South Carolina) by the state health department, and in 3 (Kentucky, Mississippi, North Carolina) by both state and local health agencies. In 5 other states (Arkansas, Florida, Georgia, Indiana, Missouri) which have adopted such regulations, enforcement is not state-wide but is left to local health officials. Six of the state regulations are based on the 1938 edition, 5 on the 1940 edition.

This ordinance, or similar ordinances or regulations based thereon, has in addition been legally adopted by 74 counties and by 123 municipalities, located in 19 states. Of these, 38 located in 4 states (Arkansas, Florida, Kentucky, Ohio) adopted the state board of health regulations, 74 located in 3 states (Alaska, Illinois, Virginia) adopted the state health department's model ordinance based on that of the Public Health Service, and 85 located in 15 states adopted the Public Health Service ordinance. Approximately two-thirds of the ordinances adopted locally correspond to the 1938 edition, the remainder to the 1940 edition.

A voluntary local program of restau-

rant sanitation with the Public Health Service ordinance used as a guide but without legal adoption is reported under way in communities in 4 states.

That additional adoptions are being considered is indicated by the reports from a number of states. Eight states are planning to adopt state board of health regulations based on the recommended restaurant ordinance, and 53 counties and municipalities located in 15 states are considering its adoption as a local ordinance.

It is evident, therefore, that the restaurant sanitation ordinance recommended by the Public Health Service is proving very popular with health officers. It is suitable for adoption by states, counties, and municipalities both large and small, and by areas which advocate grading as well as those which prefer minimum requirements. It is particularly useful at this time in connection with the sanitation of national defense areas, in many of which the ordinance is already in effect.

Engineering Health Services for Small Plants*

JOHN BUXELL, F.A.P.H.A.

*Sanitary Engineer, Chief of Sanitary Section, Health Division,
City of St. Louis, Mo.*

AS the dividing line between small and large industrial plants has been variously defined as 500 employees, 100 employees, and sometimes even less, it will be necessary for the purpose of this discussion to redefine this dividing line. For the purpose of this paper I shall define a small plant as one with less than 100 employees, and a large plant as one with 100 or more employees.

Using this arbitrary definition and census statistics,¹ it becomes immediately evident that the small plant outnumbered the large one to a great degree. Approximately 90 per cent of all of the manufacturing and mechanical industrial establishments employ less than 100 persons. About half of all of such establishments employ less than 10 persons. Thus, the small plant is the rule, not the exception. Of course, when number of employees is the only consideration, then the small plants lose some of their importance, since they employ only about 30 per cent of all workers. But from any consideration, the problem of supplying health services to small plants is a very important one.

Since fewer persons work in an individual small plant than in the large one, it can be expected that injuries and

diseases will be fewer in the smaller plant. However when the incidence of injuries is calculated on a man-hour basis, a different result occurs. Statistical studies of accidents and disease, from which an analysis of frequency and severity of such disabilities in small plants can be made, are very difficult to find. Most of the reporting of this nature comes from large plants, where accurate records of accidents and diseases are more likely to be maintained.

The largest plants reporting to the National Safety Council² during 1939 had a disabling injury frequency rate of 11.08 (disabling injuries per million man-hours worked), while the smallest plants had a rate of 17.47, or 58 per cent higher. The severity rate for disabling injuries in the smallest plants averaged 1.66 (disability days per 1,000 man-hours worked), or 21 per cent more than the large plant rate of 1.37.

There is reason to believe that a similar situation exists for incidence and severity of disease. If we believe that safety and health services are effective and thus act to reduce the incidence and severity of injuries and disease, then we are forced to the conclusion that these rates will be higher in small plants because it is comparatively easy to show that small plants now are not receiving an adequate amount of such services.

Small plants are handicapped by hav-

* Read at a Joint Session of the Industrial Hygiene and Public Health Nursing Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 15, 1941.

ing a relatively small amount of money to spend, and it has been shown by Newquist³ that the smaller the plant, the more costly are health services to employer and employee. Small plants find it more difficult to justify the expenditure of sufficient money for adequate preventive measures and equipment; they find it more difficult to pay for the technical advice necessary for proper industrial health control.

A comparison of industrial health provisions for small and large plants is shown⁴ in Chart 1 in which it will be seen that the contrast is very marked. In every instance the small plant is far behind the large plant in the health provisions shown, with the

exception of first aid kits and accident records, and even in these two services the small plant lags.

A similar situation is shown graphically in Chart 2.

This chart shows the situation in St. Louis with respect to the health services to be discussed. St. Louis has been termed a "typical industrial area" by the U. S. Public Health Service. It is interesting to note the continuous prevalence of safety director or engineering service over either nursing or medical service. It is also interesting to note that the curve for physicians rises above that for nurses in the smaller plants, but these conditions are reversed in the larger plants.

The contrast in these provisions as to

INDUSTRIAL HEALTH SERVICE PROVISIONS IN PLANTS EMPLOYING MORE THAN 100 WORKERS AS COMPARED WITH PLANTS EMPLOYING 100 WORKERS OR LESS

CHART 1

large and small plants is again shown in Table 1.

TABLE 1

Extent of Industrial Part-Time and Full-Time Services of the Physician, Nurse, and Safety Director or Engineer
(From Survey Records of the St. Louis Health Division)

Service	Per cent of All Small Plants	Per cent of All Large Plants
Safety director or engineer	2.4	44.4
Nurse	0.8	28.6
Physician	1.3	23.8
None of above services	96.5	49.2

The typical health and safety set-up in the small plant is composed of the following: a physician on call, who never sees the plant or its operations except on his emergency calls; no nursing service; perhaps a man assigned to

first aid, in a few instances with first aid training and who makes use of a small and indifferently-kept first aid kit; and an official—superintendent or owner—who devotes a minor part of his time to safety control work. No sickness records are kept in this typical small plant and only those accident records which are necessary under the Workmen's Compensation Law are available. This is the situation and it is the one that we should consider if health services are to be furnished to and accepted by the small plant.

We in public health work have discussed at some length and through a number of publications the need of helping the small plant with its health problem. But we have found it extremely difficult to apply our ideas.

According to census statistics, retab-

PHYSICIAN, NURSE, AND SAFETY DIRECTOR OR ENGINEER
(From survey records of the St. Louis Health Division)

CHART 2

ulated by the U. S. Public Health Service in *Bulletin 259*, there are some 203,000 plants in the manufacturing industries of the United States and about 8,800,000 wage earners are employed in these plants. This results in an average of 43 wage earners per plant.

Table 2 shows the average number of workers involved in studies made by various official bureaus of industrial hygiene in the United States in the 1939-1940 fiscal year.⁵

TABLE 2

Average Number of Workers Involved in Industrial Hygiene Field Studies Made by Reporting State and Local Health Departments, 1939-1940

State Reporting	Average Number of Workers Involved
Utah	3,493
Texas	849
Idaho	473
West Virginia.....	439
Pennsylvania	238
California	176
Virginia	171
Ohio	169
North Carolina.....	123
Iowa	123
Wisconsin	118

Missouri (St. Louis).....	55
South Carolina.....	55
New Hampshire.....	47
Connecticut	41
Vermont	39
Rhode Island.....	25
Maryland (Baltimore).....	4

It is perhaps somewhat unfair to cite these statistics because some of these agencies are just being organized, and also because there are valid reasons for the type of work being done by these agencies.

It is indicated that even the official agencies are finding it extremely difficult to provide adequate health services to the small plant in the proportion that they exist in our industrial set-up.

It can be safely concluded that health services now are not being satisfactorily supplied to small plants. If the small plant is to be reached by such health

services, it must be done by coöperative plans of service, by public or private subsidy, or by inventing preventive methods which are less costly, thus bringing them within the price range that can be afforded by the small plant.

So much for the basic situation. Others will discuss the provision of medical and nursing services. My part of this symposium is the engineering health services for small plants.

The public health engineer should find his task less difficult than that of the nurse or physician, for he starts with two advantages:

1. The engineer is already in action in industry. The physician may find few, if any, in the plant management who will comprehend him professionally or who can aid him professionally. Similarly, the nurse has only the trained first-aidier. But the public health engineer may find a fellow engineer at the drafting or designing table in even the small industrial establishment; the owner or manager frequently is an engineer or has been forced to learn technical terms and methods in this mechanical age. We engineers find many in industry who speak our language.

2. Safety work in industry is far advanced. Even small industry is safety-minded. One is tempted to doubt the truth of this statement when he finds glaring violations of the simplest safety principles. But much safety work has penetrated down to small industry. A great portion of this work has been mechanical and has been applied by technical men. These men are in the small plant and may serve as a nucleus around which may be built engineering health work.

It has been said that environmental control is the special province of the engineer. It seems that there has always been an attempt to divide public health activities so that certain professions or specialty-trained people may carry them through. But it is not always possible so to divide public health problems. The problem of industrial hygiene, especially, is of many facets and must be attacked and controlled by the coöperative effort of many trained individuals. I can think

of the educator, the physician, the dentist, the nurse, the biologist, the chemist, the first-aider, several types of engineers, the psychologist, and many more.

It may easily be necessary for these specialty-trained individuals to step over the boundaries of their particular fields, giving advice and service on the whole aspect of industrial health work. This may be particularly necessary in small plants where efforts of technical people are spread so thin. The public health engineer is continually plagued by this necessity of going outside his field into medicine, chemistry, first aid, nursing, education, and others. This will become more and more pronounced as the tendency of making occupational disease work into a full and complete program of industrial health continues.

Thus, when it is said that the engineer is particularly concerned with the control of the environment, it will be realized that this is not a hard and fast rule. The environment which the industrial hygiene engineer attempts to control may be not only the working environment, but may include the home, food, recreation, and all the multitude of materials and conditions which surround the individual. However, the employee outside of his working hours is merged into the general public and will be included in the health measures carried on for the general public. It is possible to influence his personal life and environment in general by engineering health services given during the working time, but up to the present such efforts have been largely educational or medical—not engineering—and have been confined to the large plants.

Thus the need for engineering health services reduces to a control of the working environment. It includes occupational disease exposures, accident exposures, sanitary facilities, welfare facilities, food dispensing, ventilation, noise, illumination, plumbing, time and

motion studies, plant layout, and many other conditions which may have engineering aspects and require engineering knowledge for their control.

There is no need to elaborate on how these problems are controlled. But how can such technical knowledge and training be supplied to the small plant?

As with nursing, medical, and other services, it is possible and advisable for small plants to pool their resources, join in a coöperative arrangement, and thereby be able to buy engineering services. This has been done to a rather limited extent with private consultants, with trade organizations, private foundations, professional organizations, manufacturers' associations, etc. The valuable service rendered by insurance inspectors and engineers is an example.

These arrangements have worked out well for some of the small plants, but sufficient time and attention and sufficient specific information are not always given so as to solve the engineering health needs of the small plant satisfactorily, and there will be some plants which will not or cannot be reached by coöperative agreements.

It is very likely that the most direct and complete approach to the extension of engineering health service to small industry is to be performed by state and local health departments, state labor departments, and similar official organizations. In order to discharge their official responsibilities, they will, of necessity, devote more and more of their efforts to small industry. This is a form of public subsidy and should be recognized as such by providing budgets and personnel which are adequate for the amount of work to be done.

Before the official agency can adequately serve the small plant, it must overcome at least three difficulties:

1. It must overcome the prejudice which exists in the minds of small plant managers

against regulatory agencies. By example of good service and fairness, this can readily be overcome.

2. It must forget the old idea that industrial hygiene is merely occupational disease control. It must render a complete engineering health service to industry. For instance, mechanical ventilation plans should be reviewed, sanitary facilities, cross-connections, etc., inquired into, and engineering health standards promulgated.

3. It must solve the problem of large numbers of plants to be serviced, and must change its program and concepts so as to include the small plant.

For example, the value of educational methods in public health work is generally appreciated by public health people. An educational campaign of one type or another can be very successful in providing technical advice to small industry, if the material can be made attractive so it will create interest and be read, if it can be made relatively non-technical in language, and if it can be given the wide distribution that is necessary.

Small industry management does not attend medical society, nursing society, safety council, chamber of commerce, and professional engineering society meetings; nor does it read our public health publications, our medical, nursing, and engineering journals.

Unfortunately, most of the educational efforts in industrial hygiene have been limited to this type of attack; one which will reach the large plant management but not the small. In St. Louis, if we want to circularize the small industries, we must prepare literature for over 2,000 plants. When the amount of technical material to be transferred and the small portions in which it must be passed out are considered, it becomes evident that a complete educational program for the small plant is no simple matter. It will take thought and time, and the program will be slow, but the result will be well worth the effort and cost. Is there

an easier way to reach these many industries?

What do the managers read? Where do they go? The answer, unfortunately, is that they are part of the general public and have practically no distinguishing features. We cannot hope to educate the general public to technical details or methods of industrial hygiene. The avenues of approach to the small plant are reduced to only a few—trade journals for some, trade organizations for some, but principally direct mail and direct contact, with the attendant difficulty of large numbers. Some types of information may be circulated through the labor organizations and through employee groups, expecting that it will reach upward to the small plant manager.

Not only in the educational campaigns, but also in plant inspections and studies, in plan examinations, and in direct contacts, will it be necessary to spend more time and more effort in the small plant. The methods of control learned in the large plant must be adapted for use in the small one. In order to do the mass work necessary, we must standardize our methods to a greater degree.

That defense slogan "It is later than you think" can be paraphrased to read "It is bigger than you think," and then it may indicate the problem of extending health services to small plants.

Perhaps I have included more than would properly be included in a paper devoted to engineering services. If so it is because it is not possible to divide the problem we are discussing in this symposium into compartments for the exclusive use of physician, nurse, and engineer. Coöperation between all the necessary technical people, which is important in the large plant, is also important in the small one. And the real difficulty is not so much a technical one as it is an administrative one; it is that of reaching the small plant

with these health services, no matter which professional group or individual is attempting it.

Medical Services in Small Industrial Plants*

CRIT PHARRIS, M.D.

Industrial Hygiene Physician, Bureau of Industrial Hygiene, State Department of Health, Hartford, Conn.

AN increasing amount of attention is being given to health problems in industry, but the criteria for grouping plants according to size are none too clear. To some people, all industrial plants having under 500 employees each are small, while to others the size is judged principally in terms of floor area, massiveness of machinery used, or the type of products manufactured. It has been pointed out that plants having under 500 workers usually cannot economically afford to provide their own complete programs of health protection. While this may be true, the needs for industrial health service should not be based solely upon the number of people employed, but upon a combination of circumstances, including the types and magnitude of health problems and the economic means for controlling them. A plant having 300 employees might have greater health hazards and might be more able to deal with them than another establishment, of a different type, having 600 employees. No effort will be made here to define or describe the small plant because such a classification would include too many different attributes to permit a concise definition covering all industrial establishments and their problems. It is conceded, however, that the plants which may be considered within the scope of this dis-

cussion usually will have under 500 employees, and that those having under 300 each will constitute a very large majority of the group.

It is also desirable to point out that no attempt will be made to lay out a pattern of medical service which can be installed in any industrial plant in the same general manner as that involving a conventional type of press or machine tool. The type and extent of health care needed in a given plant should be based upon the various health problems involved and such determinations should be made in the same way as that used in the development of a complicated manufacturing process, or the construction of a specified type of plant building.

To say that a certain plant employing 450 people should have a part-time general surgeon or physician and a full-time nurse is not adequate or scientific unless it has been determined through analysis of the various problems in the plant that these services will be adequate. A careful study might reveal that the services of a physician having special training in industrial medicine would be necessary, and that two trained industrial nurses should be employed instead of one ordinary nurse. Industry represents one of the greatest markets for medical service to be found today and the potential purchasers far outnumber those who now provide modern medical programs. They are interested in procuring any equipment and services which will be advantageous and

* Read at a Joint Session of the Industrial Hygiene and Public Health Nursing Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 15, 1941.

they will be much more interested in the "blue prints" and "specifications" of medical programs designed to meet their needs than in the "pig in the poke" variety.

MODERN INDUSTRIAL MEDICAL SERVICE

The kind of medical program being considered for small industrial plants is of the same general type as that to be found in the larger industries. They differ quantitatively rather than qualitatively. Modern industrial medical services are not limited to the surgical repair of accident victims but they also include all measures necessary to safeguard the health of the employees adequately, regardless of what their jobs or occupational environments might be. A staff of several physicians, nurses, and other workers might be required to carry out such a program in a large plant, while in a small establishment these same services might be rendered by a part-time physician and a part-time or full-time nurse. No plant should be considered too small for at least the part-time services of a physician and a nurse and, generally speaking, the larger the plant the greater is the need for more constant service until the size is reached where the nurse and later the physician should be employed on full-time bases.

THE INDUSTRIAL PHYSICIAN

The modern industrial physician recognizes the broad scope of his duties and is willing to render the type of service indicated in the plant with which he is associated. In addition to his basic medical training and special qualifications in the field of surgery, internal medicine, etc., he presumably also possesses professional skill to cope with all the occupational health problems which do or may occur in the plant. It would be impossible to itemize all of these duties here but they can be grouped under the following heads:

- Physical examinations (including preëmployment, periodic and terminal)
- Treatment of occupational disease and injuries
- Emergency care of non-occupational disorders
- Supervision of nursing, first aid and related services
- Inspection and medical supervision of the work conducted in the plant
- Control of sanitation and plant housekeeping
- Other technical and educational efforts to protect the health of workers
- Studies of the causes and effects of injury and illness, and of absenteeism

The modern industrial physician is not just the plant doctor who operates a "repair shop" for accident victims. He is the medical director and as such should be concerned with all of the industrial therapeutic and preventive measures necessary to safeguard the health of the entire plant population. Just as in handling individual patients, he should take problems of plant hygiene "home" with him and plan how best to handle these problems.

THE INDUSTRIAL NURSE

The industrial nurse is no longer visualized as just a finger wrapper. The scope of industrial nursing service has been outlined many times, but only to the extent of setting forth the basic phases. The entire field need not be described in detail because the real industrial nurse does not need such a guide book. But she appreciates advice and consultations on her efforts. Her skill, enthusiasm, and persistence will determine whether she will be looked upon by the workers as a nuisance or as an asset.

Although the personnel of the small plant medical department usually is limited to the doctor and nurse, other workers, such as trained attendants* or first aid workers may be employed.

* The 1939 Supplement to the General Statutes, State of Connecticut, Sec. 992c, defines nursing as follows:

(Cont. on page 862)

These persons do not possess the professional qualifications of registered nurses, but it must be conceded that they can render beneficial service under competent medical and nursing leadership and that there is a place for them in the small plant. But they should not be considered as adequate substitutes for registered nurses. The plant which is too small for a full-time registered nurse certainly should be able to provide this service on a part-time basis, and any plant that has enough work to occupy the time of a trained attendant or a first aid worker on a full-time basis should be able to employ a registered nurse on the same basis, either in addition to or in lieu of the less competent workers.

FULL-TIME NURSING SERVICE

Many plant officials and some physicians are of the opinion that a nurse is not needed unless there are at least 300 or 400 employees on the pay roll. There are many excellent examples to disprove this idea and one of them is cited here:

A plant in Connecticut having 150 workers recently employed a registered nurse on a part-time and probationary basis. She was instructed to take care of the first-aid work and to spend her spare time on the assembly line with other women employed in the plant. At the end of the first month she went off probation, and from part-time to full-time as the plant nurse. By this time she had several outstanding accomplishments to her credit, including the following:

(Cont. from page 861)

- a. (Registered nurse) The performing, for compensation and under the direction of a licensed physician, of any professional service requiring special education, knowledge and skill in nursing care of those mentally or physically ill and in the prevention of illness; or
- b. (Trained Attendant) The performing, for compensation and under the direction of a licensed physician, of any of the simpler procedures required in nursing care of the sick, not involving the specialized education, knowledge and skill specified in subsection (a). Effective July 10, 1939.

1. The transfer of a worker from a machine, which he could not operate properly because of a visual defect, to a suitable job

2. The transfer of a degreaser operator, showing evidence of addiction to trichloroethylene, to a safe job

3. The correction of hygienic practices and proper protection of two machine operators having moderately severe oil folliculitis, with the result that the trouble cleared up without the men having to lose time from work or be transferred to another job

4. The discovery and transfer of an epileptic worker from a job which would have been hazardous to himself and others in case of a seizure, to a safer job

All of these adjustments were brought about in a manner which was mutually acceptable to the men and the plant officials. This nurse is more than a first aid worker. She is practising a type of modern preventive nursing which is reaching all of the employees, and even into the homes of many of them. To say that the plant officials and workers are satisfied with her services is expressing the case very mildly.

This example of what a full-time, registered nurse can do in a small plant is unique in some respects but there undoubtedly are many other similar examples. Much proof also can be cited to show what the part-time physician can do in such plants. The nurse mentioned above has received excellent assistance from the physician who serves the plant on an on-call basis. If this physician had been employed on a part-time basis the accomplishments undoubtedly would have been much greater than they were.

MEDICAL SERVICES IN INDUSTRIES

In view of progress in the field of industrial medicine it hardly appears necessary to present an argument for the service. But as proof of the enormous promotional task ahead, two examples of the present shortcomings are cited here. A recent survey of potential industrial hygiene problems in the United States,¹ covering 1,487,224 work-

ers in 16,803 plants, revealed that full-time and part-time services of physicians were provided for 15.5 per cent and 22.3 per cent, respectively, of the employees, while nursing care was provided on these bases for 33.3 per cent and 1.5 per cent, respectively. In the State of Connecticut a recent study² involving 116,639 workers showed that full-time and part-time physicians were provided for 22.7 per cent and 18.8 per cent, respectively, and that registered nurses were serving 67.4 per cent and 2.5 per cent on these same bases. These figures represented the extents to which services of physicians and nurses were available for employees in all of the plants covered. The shortcomings were much more graphic in the smaller industries.

FUTURE PROSPECTS FOR INDUSTRIAL MEDICAL SERVICES

The prospects for further development of industrial medicine are very promising. The subject is at long last, and for the time being at least, receiving a measure of attention which is justified. The impetus which has been given to the physical welfare of industrial workers during the past few years has been motivated by the growing conviction that good business and good health are inseparably related, and that industrial poor health is an unnecessary and expensive industrial waste product.

At the present time almost all Americans are rapidly becoming "tooled up" to a wartime tempo with preparedness, defense, conservation of resources, and other related topics dominating the entire picture of American life. Of the many types of resources considered under the benevolence of conservation, and on the priority lists, none is of greater individual and national importance than the physical stamina of industrial workers. It is only natural, therefore, that industrial medicine

should be elevated to the level of importance which it now occupies. But if effective service is to be sustained in this sphere, it is necessary that all of the related problems be understood and dealt with soberly. Furthermore, it must be realized that whatever heights are reached during the present national emergency probably will not be entirely adequate even for normal periods of industrial activity. So the present programs for the extension and improvement of industrial medical service must be prosecuted, not only for the purpose of protecting defense workers, but to insure to all future employees safer working conditions than were found at the beginning of the present emergency.

THE CONNECTICUT PLAN FOR EXTENSION AND IMPROVEMENT

Although a very large percentage of industrial workers still are without adequate health service, there are many encouraging indications that the medical and nursing professions will do their part to eliminate this shortage. The interest which is being manifested in the State of Connecticut serves as an excellent example. The Connecticut State Medical Society and the Manufacturers' Association of Connecticut have been coöperating for some time in studies of the industrial medical problems and of ways and means of improving and extending the service. The basic policies and objectives already have been set forth in a brochure, *Conservation of Man Power Through the Extension and Improvement of Industrial Medical Service*. A second step which now is in its final stage of completion involves a statistical study of the extent to which medical care and facilities are provided in Connecticut industries. The third, and by far the most important step, involves a state-wide effort to point out the importance of adequate industrial health protection. This campaign will deal with two major

groups — physicians and individual plants. Some phases of the project already have been started but they are to receive much greater attention in the near future. The medical profession will continue to sponsor postgraduate training in industrial medicine through seminars, special society programs, and other means which may be indicated as the program expands.

The Manufacturers' Association certainly can be relied upon to enlighten industry further concerning the importance of adequate medical care of workers. In addition to the general promotional efforts which these two organizations will carry on, plans are being further developed for rendering consultation service to individual physicians and plants concerning their specific problems.

Organized labor long has been concerned with industrial health problems, and labor leaders have made very substantial contributions to the drive for better working conditions in Connecticut. They, too, can be counted upon for continued coöperation and their efforts already are being reflected by the individual workers, who are displaying intelligent and constructive appreciation of their responsibilities in this field of a higher type than ever has been observed.

Tribute also should be paid to the industrial nurses in Connecticut. They realize their opportunities and responsibilities to coöperate with others in measures which will elevate and extend the service. Leaders among the industrial nurses in the state feel that their branch of the profession is, or should be, on the same high plane as those which are limited to private nursing care of the sick, public health nursing, or other special fields. They are proceeding along the same general lines as those mentioned above for the physicians, and it may be confidently predicted that this field of service soon will surpass any previous levels of perfection.

The Bureau of Industrial Hygiene of the Connecticut State Department of Health has enjoyed a close coöperative association with the State Medical Society, the Manufacturers' Association, and industrial nurses, in the various phases of the program outlined above. The bureau has no specific responsibilities or duties in regard to industrial medical service, and only proposes to render helpful assistance. It is felt that, if each plant in the state could have adequate industrial medical service, much more effective control of occupational disease hazards could be realized than is the case today. The bureau naturally is anxious to coöperate in any measures which will be for the attainment of this goal.

This outline of organizational and promotional effort in Connecticut was given here to show that logical and sensible efforts are being made in more than one camp to bring about the type of industrial health protection which will be adequate to meet the needs in individual plants and which will be respected and utilized by the beneficiaries. These services will be offered to industries on "tailor made" bases so as to insure that the type and extent of care needed, as revealed by specific plant surveys, will be provided. The small plants will be on the priority list, and every effort will be exerted to guarantee their workers medical care equal in quality to that to be found in the larger plants. This program is not simply concerned with the present industrial situation but is also being developed with the objective of insuring to all industrial workers that every effort will be made to protect them against their jobs and their jobs against them.

A CALL FOR PUBLIC HEALTH STATESMANSHIP

IT seems quite probable that as the war goes on, a medical situation, heretofore somewhat humdrum and certainly neglected, will assume such proportions as to demand solution. This is the problem of distribution of medical practitioners. Thoughtful physicians, public health workers, and many of those in fields collateral to medicine have been worried about this matter for a number of years. That there has been a plethora of physicians in urban centers and a dearth in rural areas has been no secret. It has been well known, too, that the ratio of physicians to population in one section of the country has been markedly out of proportion to that ratio in another.

The factors which have contributed to this situation are fairly obvious: adequacy of hospital facilities in one place as against their absence in another; the mental stimulation of the medical center in contrast to the danger of professional stagnation in the outposts; the more abundant life socially, culturally, and financially in the urban and prosperous communities, and the lack of these inducements and advantages where there are few people and less money. Occasionally some community, with the only practitioner dead of senility, has gone so far as to offer a subsidy in an effort to attract a physician to settle there, but in general no group has seemed willing or able to undertake, systematically, the solution of this problem. Of the many deterrents, two perhaps have been foremost. First, and quite properly, no governmental or non-governmental agency has had the authority to tell the young physician that he must go to a certain place to practise and make his home. Second, there has been the fear that any wide-scale activity related to the placement of physicians, even in an advisory capacity, might lead to some form of regimentation of the medical profession and to socialized medicine. The result of all this has been what one would expect: demand and supply have operated in a manner not nearly so satisfactorily as the *laissez-faire* group would have the public believe, but not nearly so distressingly as is proclaimed by those who, afflicted with a sort of phantom sociorrhagia, bleed vicariously for mankind.

Be all this as it may, it seems likely that the channeling of physicians into the military services will transform what was in the past a tolerable situation into an intolerable one. As nearly as can be gathered, the distribution of physicians in the United States, by ages, is somewhat as follows: under 36, some 42,700 or 24 per cent; ages 36-44, about 38,200 or 21.7 per cent; 45-54, approximately 31,900 or 18.1 per cent; and 55 and over, around 63,300 or 36 per cent. It is the 80,900 physicians under 45 years of age in which the military services are most interested, interested to the extent of needing 45,000 (including those already in the services) by December 31, 1942. This means about one out of every two physicians in that age group will be lost from their communities. And this will not be the last of it. Present indications are that, barring some unforeseen collapse in the Axis powers, the war will be a long one, and further and continuing inroads must be made on those who will be engaged in civilian practice in 1943 and 1944, and on until the end. Common sense indicates that measures must be taken to insure, on a national basis, the most sensible and effective use of those comparatively few civilian physicians who are not called to military service.

It seems exceedingly doubtful that this best use can be assured on a voluntary basis. It is hard to visualize a physician, with a comfortable urban practice, voluntarily abandoning his local prestige, his hospital affiliations and facilities, his accustomed routine, and his assured income for the exigencies of what, in many ways, would be a new start in uncomfortable circumstances, with the nearest hospital thirty miles away. And one cannot blame the physician for failing to volunteer for this sort of work, especially as some of his competitors would remain in the community he had left, would serve his patients, and when he returned some years older, he would not only have lost his practice, but would have to meet the competition of the returning medical officers with their hard-won right to preferential consideration.

Is the answer to the problem to draft all physicians into one of the present services, or a service to be created, and detail them to this place or that, as is done in the Army, Navy, or Public Health Service? We do not know the answer, and, at the present writing, we are inclined to suspect that anyone who is aggressively sure that this is the answer, or is similarly aggressive in saying it is not the answer, evidences prejudice and approaches error in direct proportion to this vehemence. And it is unlikely that either the threadbare clichés of the traditionalists or the wails of soap-box socialists will contribute to solving the problem. It was all right to listen to these champions in the leisurely days of peace, but with the situation as it is, they come under the general heading of annoying, if not dangerous, pests. But time is passing, and increasingly the problem presses for solution. Unselfish and authoritative leadership, with first interests focused on solving this problem, is what physicians and the people now want. And they want it very much and at once.

WHAT AND WHO IS AN EPIDEMIOLOGIST?

Comments on an editorial published in the April, 1942, issue of the JOURNAL.

Our thanks are due John R. Paul, M.D., Professor of Preventive Medicine, Yale University School of Medicine, for the following:

In seeking the answer to the nice question posed I am prompted to define certain qualifications which one might seek in a man to head up a department of epidemiology in a hypothetical medical school. These qualifications depend, of course, on one's definition of Epidemiology, and, if forced to give this in a sentence, one could say that Epidemiology is that subject (not yet elevated to the position of a science) which deals with the circumstances under which people get sick. Such a definition does not imply that epidemiology is limited to infectious diseases or to epidemics, or that one necessarily has to deal with *many* sick and *many* well people in order to "practise" epidemiology. Zenker elucidated the epidemiology of trichinosis from one case; and there is a growing list of examples of the study of *familial epidemiology* in which much was learned from but a few families.

With this clinical approach in mind, the qualifications of our hypothetical candidate should consist in:

A clinical background—He should not only have had clinical training but it is desirable that this training should have struck deep enough into his soul so that through the greater part of his working life he could maintain the clinician's point of view, because epidemiology deals with sick people. This maintenance of the clinician's point of view does not necessarily mean that he must keep up membership in the county medical society, but he should keep up contact with patients and should bring *clinical* judgment to bear on his prob-

lems rather than other types of judgment. He should not have to resort to scattergrams to show that all individuals of the same age group are not alike. His diagnostic methods are apt to be more like those of a detective than of a "trouble shooter." He should regard all clinical data with healthy suspicion.

The training for this should be an M.D. degree, an internship, and perhaps an assistant residency on either the medical or pediatric service in a good hospital; or even an assistantcy in one of these departments in a medical school. This experience should serve to put our candidate on either one or the other side of the fence, which separates the sheep from the goats. The distinction is important, if we believe in the words of Dr. Theobald Smith, who stated that by their very nature the clinician and the public health man use different methods in their approach to problems of human disease.

Bacteriological training—Early in the candidate's postgraduate career (probably during his assistant residency) he should be exposed to a certain amount of *responsibility* in the handling of bacteriological methods. These methods should include work with bacteria, viruses, or protozoa, and work in clinical immunology—subjects which perhaps come to life best in a hospital laboratory. Such clinical bacteriological training is important, but of course it is only one part of the picture, for bacteriology is certainly not epidemiology.

Statistical training—Having followed

our candidate through a clinical and laboratory course of sprouts, we come to the most difficult part of his training. He should be willing to interrupt his career long enough to familiarize himself with statistical methods so useful to the practice and study of epidemiology. Knowledge of such methods is of great value. That they are the beginning and end of epidemiology is doubted, even though one occasionally finds a "portentous epidemiologist" who seems to be equipped only with statistical tools and someone else's figures.

Experimental epidemiology—It is also possible, though unlikely, that our candidate may have taken a year off to try his hand in the field of experimental epidemiology; but so far relatively few investigators have developed this important subject.

Experience with field work—Our candidate would be fortunate indeed if early in his career he could have the opportunity of applying his bacteriological and statistical methods in the study of disease in the field (*viz.*: in the home, in an institution, in the factory, or in a small or large community). This experience is really training in Clinical Ecology—and if it "took," he would probably never be happy doing "office" work alone.

Experience with "public health epidemiology"—Useful also would be some

experience in the epidemiological division of a municipal, county, or state department of health. Probably more positions of this type exist than in any other branch of the subject, and so it is this particular aspect that comes to one's mind when the title "epidemiologist" is mentioned.

Formal training—The question of formal schooling, of degrees and courses in epidemiology might be raised. Such training would be nice but it seems to be the least valuable of the experiences already mentioned. It carries with it the risk of substituting overtraining or stagnation in lecture halls for years that might better have been spent in enthusiastic work in the field or laboratory. The advantages of such training are that they may aid an individual in his search for certain kinds of jobs. But while theoretical training may be an introduction, it should never be a substitute for the practical experience needed by our candidate.

At this point it becomes obvious that one would have to seek far to find our candidate. Perhaps there are no such individuals and no medical school ready to use them. Perhaps this is the real answer to the question which the editorial has raised, and so the discussion as to what and who is an epidemiologist really brings us to another point, namely: Where is there an epidemiologist?

Signing himself as "Retired Epidemiologist," Allen W. Freeman, M.D., Professor of Public Health Administration, The Johns Hopkins University, lets fly this searching but good-natured broadside:

The epidemiologist is the fellow who gets to town at the peak of the epidemic and coasts to glory on the down or eastern leg of the epidemic curve. He goes around with a sheaf of case cards in his hand and knocks on front doors, asking impertinent questions. When he has drained the community dry of what

he then calls pertinent information, he goes into a huddle with a Monroe machine and comes out with a paper for the Epidemiological Society (by invitation). When he is too old to walk from car to door he becomes a statistical or armchair epidemiologist, or in extreme cases a professor.

Epidemiologists are not born ready made. Like diamonds, they are produced by the prolonged and skillful shaping and polishing of suitable raw material. Many sorts of raw mate-

rial may be processed into epidemiologists, even, occasionally, bacteriologists. County health officers seem to make the best product.

James E. Perkins, M.D., Director, Division of Communicable Diseases, State Department of Health, Albany, N. Y., says this, in a letter to the Editor:

I cannot completely ignore the shoulder chip flipping Editorial in the April, 1942, issue of the JOURNAL. It really is not surprising, however that a query is made as to the means of identification of an epidemiologist since there are no obvious insignia designating these rare individuals (particularly rare if one confines discussion to the "epidemiologist vera"). Even the Johns Hopkins School of Hygiene and Public Health doesn't give a degree of "Doctor of Epidemiology," so it is obvious that an epidemiologist cannot substantiate his status by a beautifully scrolled certification to that effect. But an *epidemiologist* can tell *another* epidemiologist unerringly. It's like sex in the flea: "the sexes look alike, you see, but *he* can tell, and so can *she*!"*

As hinted above, there are two classes legitimately designated as epidemiologists. The first class comprises a broad group of individuals ("epidemiologist expansa") who are more or less authorities in "the science of mass pathology." A layman who has engaged in researches entirely devoted to gleaning from past literature shifts in the geographical and chronological distribution of diseases may perfectly well qualify as an epidemiologist in this class. He may, in fact, be much more entitled to the designation than a recent medical school graduate who, in order to fill empty and somewhat ragged pockets, accepts temporarily a position bearing the title "epidemiologist" in a local or state department of health.

Then there is the narrower definition

of "epidemiologist." This restricted use of the term refers to an individual who, through training, but chiefly through heredity, has an unusual capacity to ferret out epidemiological data through actual field investigation. He is an individual who, as Dr. Godfrey says, has "an insatiable curiosity and a healthy skepticism." But he must have other qualities as well. He is merciless to shoe leather. He has a tactful aggressiveness and a reasonably thick hide, which enables him to ascertain from the housewife, as she does the weekly wash, the exact day two and a half weeks ago Aunt Hattie from the city visited the home with her ailing youngster, and enables him to secure specimens of body fluids or discharges in spite of a reluctance on the part of the owners thereof to part with their precious secretions or excretions. It is in this latter restricted sense that one hears the statement, "Now, there's a true epidemiologist!" Hence, the species designation, "Epidemiologist vera." Even though this is a more restricted group, its membership distinctly is not confined to physicians. Many a public health nurse and lay investigator has been appropriately revered as an *Epidemiologist vera*.

The one quality which I have yet to see in one considered to be an epidemiologist by those capable of evaluation is "portentousness of manner and mien," mentioned in the Editorial. Epidemiology is a science, and an epidemiologist worthy of the name has the humility, objectiveness, and dislike for affectation characteristic of the scientist.

A Selective Digest of Diversified Health Interests

D. B. ARMSTRONG, M.D., AND JOHN LENTZ, M.S.

THE PUBLICATION PARADE

There is one very stimulating thing about writing a health education section for the *Journal* and that is we seldom have to plow through a lot of uninteresting material in order to unearth publications worthy of endorsement. Rare indeed are there publications which are so inferior that we think best to cast them aside. Here, then, are some items which have brightened our days during recent weeks. At the head of the summer publication parade, we would place:

The New Milwaukee Cook Book, issued by the Visiting Nurse Association, 1038 North Cass Street, Milwaukee, Wis., and priced at \$1.50 per copy. (Spirally bound.)

Most cook books, at least to the average person, are about as interesting as worn-out vaudeville jokes. But the Milwaukee group has succeeded in presenting a cook book that is novel, original, and attractive. The first section of this publication is entitled "The Cocktail Hour" and it lists "the makings" of a number of favorite drinks from mint julep to eggnog. Following this section, the book is given over to the pet recipes of various Milwaukee citizens—and the mere reading of these is enough to create a healthy appetite. The recipes, incidentally, are not printed in type, but are reproduced in the penmanship of the various contributors. Humorous pen-and-ink sketches appear throughout the con-

tents. From the standpoint of the mere male reviewer, the only criticism that can be made of this publication is that the recipes might be a bit more detailed. On the whole, however, this cook book is excellent and should enjoy wide popularity. Other health agencies seeking ways of raising funds should examine this, for it has all the appeal of a best seller.

This Is Medical Care in Connecticut, published by the Connecticut State Medical Society, New Haven, Conn.

This is a distinctly admirable publication and to our knowledge no other state medical society has succeeded quite so well in interpreting the physician, in his various capacities, so comprehensively and attractively for the information of the public. By means of photographs and a few words of text accompanying each picture, a complete review of public health and personal hygiene measures in Connecticut is conveyed to the reader. In fact, extraordinary skill in condensation is one of the distinguishing features of this booklet. The booklet is an effective educational device and it should create among the citizens of Connecticut a feeling of pride in the medical resources available to them.

National Foundation News, a periodical published by the National Foundation for Infantile Paralysis, 120 Broadway, New York, N. Y.

Although this is not quite a new publication, it has recently been re-designed and is now appearing in a new streamlined format conceived by Normal Bel Geddes, the famed originator of the

Please address samples of printed matter, comments, or other editorial contributions to the editors at One Madison Avenue, New York, N. Y.

Futurama. and creator of the modernized Ringling circus. It is hardly necessary to add that this publication is up-to-the-minute as regards layout and typography. These features, combined with the publication's unusually well written news items, make this a periodical worthy of forthright critical approval. Incidentally, have you seen the promotional letter sent out by the Foundation on its film, "A Report to the People"? Aside from the convincing copy, reader interest is stimulated by a novel device attached to the stationery. It consists of numerous "stills" from the film, folded accordion-like, and printed to simulate a strip of motion picture film. This gives the prospective booker of the film a "preview" on paper, and the effect is quite pleasing.

— — — —

Several noteworthy annual reports ranging from modest, compact statements to expensive and elaborate presentations, deserve recognition in this publication parade.

— — — —

We commend Dr. I. F. Thompson, Commissioner of the Racine, Wis., Department of Health upon his summary of activities for the year 1941. In this report, a new technic of interpreting health work is utilized. Readers may recall an article by the late Dr. W. Frank Walker entitled "Rating My Town's Health Work" in which Dr. Walker took accepted standards of health conditions and health procedures and presented them so that one might be able to judge whether health programs in any community measured up to accepted standards. In the Racine report, Dr. Thompson has ingeniously used the yardsticks of Dr. Walker to measure the work of his department so that the people he serves may know how nearly their health agency approaches desired standards. Quotations from the article of Dr. Walker, pertaining to various

phases of health department activities, are printed in red. Accompanying these quotations, are notations regarding the Racine activities. It is an excellent scheme and it makes for a singularly interesting and readable report. Another touch that we like is the signature of Dr. Thompson at the end of the foreword. It is not a facsimile reproduction, the Health Officer having signed the reports personally. As for content, the 1941 statement reflects a most outstanding record of progress on the part of the Racine Health Department.

Other 1941 annual reports of considerable merit include the following:

Mental Hygiene—Ally of Victory, published by the National Committee for Mental Hygiene, Inc., 1790 Broadway, New York, N. Y.

Here is a report which prominently features the relation of mental hygiene to the war. "Clear minds and unclouded vision" are necessary if we are to put forth our best effort, and the report points the way to bring these about. The cover, illustrations, typography, and text of this statement are done with outstanding skill.

Annual Report of the Children's Memorial Hospital of Chicago—Enhanced by an appealing cover portrait of a young child, well organized contents, and exceptionally good illustrations, this report stands head and shoulders above those issued by most hospitals. Being safety-minded, we were surprised to note that one of the photographs in this volume unconsciously pictured a most conspicuous indoor accident hazard (page 61)! Aside from this flaw, the entire report is indeed meritorious.

Two reports that reflect the current trend toward the compact, abbreviated type of annual statement come from the National Tuberculosis Association and the New York Tuberculosis and Health Association. Both are brisk, readable, and well printed little

volumes. While the longer report may be more satisfactory for certain purposes, we like the "capsule comment" of each of these statements. Both reports are pleasingly bound, and we congratulate the writers for packing a considerable amount of material into a limited amount of space.

AN EDITORIALETTE:

"NATURE'S COURSE"

Herewith we offer our first guest editorialette, submitted in response to invitations extended in these columns during recent months. Dr. Bruno Gebhard, Director of the Cleveland Health Museum, has written the following:

"Let Nature take its course" is one of those sayings which can be quoted rightly or wrongly. Nature is Man's friend and enemy. Man has learned to use Nature's powers to build up what we usually call civilization and culture. But he has also used Nature to tear down civilization.

More and more we are moving away from Nature but are still a part of her. Nature's "course" is practically, "How shall we live, and how shall we live together?" In preventive medicine we no longer allow Nature to take its course. We vaccinate and we immunize. We do not allow people to become ill where it is not necessary.

Too often parents and teachers refer to Nature's course, trying to dodge educational responsibilities. There is no doubt that the recommendation "Let Nature take its course" is justified where experience means more than knowledge. But there is no excuse for holding back facts which should be known by everybody. Ignorance is seldom bliss or identical with purity.

(EDITORIAL NOTE: These columns are still open to other contributors. Please let us have your comments on any subject—preferably with a health education slant. While we cannot guarantee publication, serious consideration will be given to all material submitted.)

RADIO NOTES

Two volumes of radio scripts—each containing 26 separate dramatizations on a wide range of health topics—are

available from the Baltimore City Health Department, Baltimore, Md. These volumes are a compilation of the radio programs that have recently been sponsored by Dr. Huntington Williams in his "Keeping Well Series." Each volume is priced at \$5.00, while copies of individual scripts are offered at a cost of \$1.00. In view of the excellence of the material and the substantial way in which these scripts are bound, we commend this as a good investment for any health department interested in inaugurating a radio program.

The "Keeping Well Series" has been aired from Baltimore over a period of several years and is considered one of the most conspicuously successful health radio programs yet offered the public. The reasons underlying Dr. Williams's success in this medium are readily apparent to anyone who examines the scripts. In the first place, a versatile writing talent has gone into the preparation of these dramatizations. In the second place, in spite of frequent failure with this method in health education elsewhere, each script is built upon a good dramatic pattern—with just enough health content to put over the desired message and just enough entertainment to hold and sustain audience interest. Each of the scripts has general appeal and there is no use trying to list the best ones; everyone will have his own preference. Audiences will probably listen and learn wherever these scripts are broadcast, and health agencies would do well to look into the material offered by the Baltimore City Health Department.

"Shadow Over the House," one of a series of radio transcriptions produced by the U. S. Public Health Service, was accorded high recognition by the Thirteenth Institute for Education by Radio at a recent meeting held in Columbus, Ohio. The script, written by Oscar Saul of the Division of Sanitary Reports and Statistics, received one of the two

awards for the best dramatizations of 1941. This transcription is one of the few health education programs that have received such recognition and it is hoped that the award will result in a more general acceptance of health transcriptions by radio station managers. "Shadow Over the House," and other transcriptions dealing with varied health subjects treated in dramatic style, are available on loan without charge from the Public Health Service or the U. S. Office of Education, Washington, D. C.

"How to Use Radio" is the title of an informative pamphlet published by the National Association of Broadcasters, 1626 K Street, N.W., Washington, D. C. This publication was prepared especially for teachers and radio chairmen making their debut as program sponsors. The booklet covers the subject thoroughly, embracing such topics as the selection of speakers, script writing, preferences of the listening audience, and that bugaboo of all radio amateurs—mike fright. The booklet is priced at *3 cents per copy*.

A NEW USE FOR WINDOW SHADES

Lucile Hook Hamlin, Associate in Public Health at the University of California, has described an ingenious method for the presentation of statistical data in the classroom. Since many health workers are frequently required to present such material during public lectures, it would perhaps be serviceable to describe Miss Hamlin's method in some detail so that others may put it to use.

In teaching vital statistics and biometry it is frequently necessary to present graphic and tabular information to classes. Blackboard presentation is time-consuming and subject to errors of transcription. Moreover, in those classes in which the same material is used progressively through the school semester, blackboard work becomes a tedious chore. Investigation of ways in which statistical information might be permanently

and accurately recorded led to the use of paper graphs, size 3 feet by 3½ feet, mounted with vegetable paste on plywood. This arrangement, however, involved difficulties such as warping, the necessity for considerable storage space, heaviness, and expense.

A method of graphic presentation which is entirely satisfactory and practical with respect to preparation, presentation, storage, and expense is found in the use of an ordinary window roller shade. Sizes of approximately the same as that of the mounted paper graphs (3 feet by 3½ feet) can be bought at most stores. The material of the shade takes pencil and ink, it withstands frequent erasure, and does not smudge. A wide range of color selection makes it possible to obtain an off-white color that reduces glare to a minimum. The brackets which are used to secure the shade over a window may be fixed into the wall molding of the classroom. The desired shade-graphic is easily slipped into place, to be drawn at the appropriate time. If conditions permit, brackets may be secured in position in the storage room, where the roller shade-graphic may be kept when not in use. The rolled shade is easy to carry, and the graph is preserved in excellent condition.

When it is necessary to present numerous data in a tabular or graphic form for teaching purposes, the window roller shade is an inexpensive and practical method.

AN EXHIBIT CONTEST

Here is a good tip on ways and means of acquiring needed exhibit material—as carried out by Yolande Lyon, Public Information Secretary of the Buffalo and Erie County Tuberculosis Association, Buffalo, N. Y.:

"The Buffalo and Erie County Tuberculosis Association acquired 24 original tuberculosis window exhibits last spring as a result of a contest which it sponsored among commercial art students of the Buffalo School of Fine Arts. The undertaking grew out of a need for visual education material in a section of Buffalo chosen by the Association for an intensive health education program because of its consistently high tuberculosis death rate. The rules of the contest provided that exhibits should be no more than 30 inches in any dimension, that they should all be three dimensional, they must allow for flicker lighting effects, be of durable construction and portable, and measure up to the standards of commercial advertising matter.

"To give the participants in the contest some understanding of tuberculosis as a community problem, the health education secretary took part in the exhibit work conferences, which involved actual planning and construction by the students. The exhibits were completed within a month's time and the awards were made at a special showing and tea for the directors of the Tuberculosis Association and the Art School and other invited guests. Judges for the contest included the president of the county medical society, the director of the health department's tuberculosis division, the director of the local visiting nursing association, the representative of a Negro women's group and others. Excellent opportunity for publicity was provided at each step of the project.

"The contest had several clear-cut results. It brought to the Association 24 individually designed window exhibits which, if they had been commercially made, would have cost approximately \$500. It was a means of getting across to the Art School students and their families the facts of tuberculosis prevention. The contest was also a means of promoting good will. Today the exhibits are being circulated in the territory covered by the Association and will continue to be routed to spots where they will do the most good."

THE MEANING OF LOYALTY

Although the following quotation is not closely pertinent to the field of public health, these are days when loyalty is uppermost in our minds and it is appropriate that all of us, regardless of our calling, consider the meaning of this quality in its truest and fullest sense. Here, then, is a definition of loyalty as expressed by Dr. Samuel Standard, Assistant Professor of Surgery, in an address to a recent graduating class of the New York University Medical School:

"The best evidence of a friendly, understanding, tolerant, and able faculty is an alumni group that is loyal. And what is this thing called 'loyalty'? It is difficult to define. It expresses itself as a vague feeling of gratitude and affection without value received. It isn't something that is bought and paid for. It isn't purchasable on an open market. It is no 'quid pro quo' arrangement. It is created from an unprovable feeling that what was given was given open-heartedly, freely,

with only the kind hope that the recipient would find happiness and comfort in it. It is not arrived at by logical or mathematical equations. It is difficult to understand as a reasonable conclusion—it must be felt as a vague, intangible, responsive warmth of welcome, a deep sincerity, that leaves an indelible imprint which is unforgettable, and is remembered long after the deed which it accompanied is forgotten.

"Of such gossamer-thin ingredients is loyalty woven. Yet, once woven, it is indestructible; and there is no other way to weave it. It cannot be demanded, commandeered or bought. It must be earned. Any attempt to enforce it is doomed to failure. The loyalty this school expects of you is the loyalty it has earned—no more and no less."

JOTTINGS

When vacation days loomed on the horizon this year, one of us wondered whether we should hie ourselves away and play as usual or make our respite from the job "a busman's holiday" by visiting health departments. We decided that the latter would be a highly profitable way in which to spend a wartime vacation—and so it was. There is nothing that renews one's faith in the cause of public health so much as observing the profession in action. Thus, we return to our editorial chores fully convinced that we are fortunate indeed to have these pages at our disposal to sing the praises of a truly great calling. In our ramblings from one place to another, we met and talked with health officers, sanitarians, public health nurses, health educators, and other workers. From these associations, we have gleaned the following impressions and viewpoints. . . . Many health departments are facing crucial circumstances. Demands for health services are mounting day by day. Trained personnel is needed as never before. Yet, workers are being called from their posts to meet the demands of the armed forces. Admirable as is the response, still the home front must not be neglected. Of all structures, that of

public health should be left intact. We saw health officers almost in the throes of despair over the situation. How can we meet the public's demands with depleted staffs? This question was posed over and over again. . . . We find that the Cleveland Museum of Health is stimulating health agencies in many sections of the country to produce effective exhibits. Dr. Gebhard's pioneering work is rightly bearing fruit. . . . Careful attention is being given to the planning of community health meetings. Entertainment, as well as education, is given due consideration by program planners. . . . Health officers are becoming increasingly cognizant of the value of cultivating good press relations and the newspapers, in turn, are giving health news liberal amounts of space. . . . The colorful posters of the U. S. Public Health Service on syphilis and gonorrhea brighten the quarters of many health departments. They command the attention of the public, too. . . . "Give us more material on infant and child health" was a frequent request which we encountered. . . . Have you ever thought of a vaccination scar as "a health trade mark"? We heard a health officer ask a child if he might see her "health trade mark." She immediately responded and proudly displayed her vaccination scar. . . . Health workers, particularly nurses, are responding nobly to a tremendous job in communities surrounding defense plants. . . . The nutrition program has created widespread interest among all classes in proper foods, their consumption, and preparation. . . . We find that the articles of Paul de Kruif are widely read and quoted. . . . Dr. Harry Mustard's *Journal* editorial on telephone etiquette has had a marked effect on secretaries who are fast learning "how to win friends and influence people" over the wire. . . . The owner of a chain of theatres reported that good health films were welcomed by his

patrons. . . . The following slogan, used by a candidate for a public legal office, was noted: "Elect me and I will help build a wall of health around this community." . . . And speaking of slogans, we saw this one (not in a health department, mind you!) in a drugstore which was promoting the sale of a well known deodorant: "Under arm defense—for a nation under arms." And that, it strikes us, is the height of something-or-other in slogan phraseology. . . . Prediction of a health officer: "Following the war, public health will truly come into its own. The public now recognizes its great value to humanity and tomorrow's world may well bring the golden era of the profession."

ADDENDA: Two more slogans received just before going to press—(1) "Today's Ills Equal Tomorrow's Bills—Today's Health Equals Tomorrow's Wealth" (from Florence Fiske of the Kalamazoo, Mich., Tuberculosis Association, (2) "Health Is a Go-Sign to Victory" (from David H. Meimelstein of Baltimore, Md.). . . . If you have access to *The Lancet*, one of the leading British medical journals, do not fail to read its weekly feature entitled "A Running Commentary of Peripatetic Correspondents." You will be amused, delighted, and enlightened by the varied observations recorded in this unique bit of medical journalism.

MAGAZINE ARTICLES

Recent popular magazine articles on health or of medical import:

"Discovered: An Accident Germ." Gretta Palmer. *Coronet Magazine*, July, 1942.

"The Threat of Undulant Fever." Harold J. Harris, M.D. *Parent's Magazine*, July, 1942.

"Health for the Backwoods." J. D. Ratcliff. *The New Republic*, June 8, 1942.

"One Disease Everybody Has." Gretta Palmer. *Cosmopolitan Magazine*, July, 1942.

"Varicose Veins." Maxine Davis. *Good Housekeeping Magazine*, July, 1942.

"If You Break a Bone." Louise Fox Connell. *You Magazine*, 1942 Summer Issue.

"Now Is the Time To Have Children." Paul Popenoe. *Ladies' Home Journal*, July, 1942.

"Vitamin Insurance." Forrest Williams. *You Magazine*, 1942 Summer Issue.

(The above is not presented as a complete list and the articles cited are not necessarily recommended.)

FILM NOTES

To our list of recommended films, we are happy to add the following with the suggestion that health agencies will find the first highly useful for professional education purposes and the second equally valuable for lay instruction.

(1) *Immunization Against Infectious Diseases*, produced by Lederle Laboratories, Inc., 30 Rockefeller Plaza, New York, N. Y. Length, three reels. Silent, 16 mm. version. Available to health departments without cost.

This is a remarkable film in that it contains color shots of actual cases of the more important acute communicable diseases—including such relatively rare ones as rabies and smallpox. The photography is of high quality and the content of the film is thoroughly accurate, as evidenced by the fact that the picture bears the approval of the American Academy of Pediatrics. The film, in addition to the case material presented, contains data relative to the geographical distribution of the diseases, methods of immunization, the number of doses and the amount of the

injections administered, and other factual material. The film was made by Drs. Charles F. McKhann and Harry A. Towsley of the University of Michigan Medical School. The picture is not suitable for lay groups, but it may be shown to advantage at staff meetings or other gatherings of health personnel. It would be especially valuable for showing to public health nurses or before groups of health workers taking "refresher" courses. This picture is scheduled for exhibition at the American Public Health Association convention in St. Louis in October. By all means see it.

(2) *The Modest Miracle*, produced by Standard Brands. Available in two versions: one running approximately 20 minutes and prepared for showing to community groups and the like, and one running 10 minutes and designed for theatrical use. Both 16 and 35 mm. prints, in sound, are offered. No rental fee. Consult Standard Brands, 595 Madison Ave., New York, N. Y., concerning bookings.

From the standpoint of entertainment, *The Modest Miracle* is excellent. The scenario is developed around the story of the 25 years of work leading up to the synthesis of vitamin B₁—as thrilling a story as can be found in the annals of nutrition research. The work of such investigators as Eijkman, Funk, and Williams is dramatically described in a series of well staged episodes. The cast is made up of actors of considerable ability, the sets are realistic, and the photography and sound are of high quality. There are only two aspects of this picture that one might criticize: it perhaps overemphasizes the importance of enriched bread in the diet, and the dedication is a bit "stuffy." Otherwise this is a top-notch production.

BOOKS AND REPORTS

The Modern Treatment of Syphilis—By Joseph Earle Moore, M.D. (2nd ed.) Springfield, Ill.: Thomas, 1941. 674 pp. Price, \$7.00.

Those who are familiar with Moore's first edition will welcome the augmented data and discussion of the second, while others will appreciate this comprehensive monograph not only as a valuable compilation of the literature but as an indispensable source.

Dr. Moore needs no introduction to syphilologists, but for the sake of others it should be said that he is Physician-in-charge of the Syphilis Division of Johns Hopkins Hospital, an outstanding member of the Clinical Coöperative Group and for many years one of the leaders of the medical profession in matters pertaining to syphilis.

His first edition has been a most valuable text of diagnosis as well as treatment from the viewpoint of the internist. Without impairment of the clear and logical style of the original, the second edition adds much new material. Included among this are sections on infectiousness, the use of Mapharsen, the oral bismuth therapy, the results of treatment, primary optic atrophy, the diagnosis of congenital infection, the interpretation of serologic tests, the public health aspects of syphilis and intensive arsenotherapy. The latter is of particular interest at a time when little but approbation of the method is to be heard. Not the least valuable of the features of this text is an excellent index.

As Dr. Moore says, the venereal disease control officer "should combine in himself public health experience and a wide clinical knowledge of syphilis" since the only available approach to the problem of control is through case find-

ing and therapy. Careful study of this text will prove a valuable adjunct to the experience of the expert as well as instructive to the inexperienced.

W. A. BRUMFIELD, JR.

Modern Medicine. Its Progress and Opportunities—By Netta Wilson and S. A. Weisman, M.D. New York: George W. Stewart, 1942. 218 pp. Price, \$2.00.

This book should stimulate the interest of senior high school or junior college students in medicine and its allied subjects. Its fifteen chapters outline landmarks in bacteriology, parasitology, physiology, cardiology, surgery, endocrinology, nutrition, anesthesia and other phases of modern medicine. Each subject is dramatically introduced by a historical or other interest-arresting anecdote and then developed simply, vividly, and, in the main, accurately up to its 1942 status. The chapter closes with a description of the respective career opportunities and the studies which will fit the candidate for such work.

Not all of the anecdotes seem to the reviewer to be in good taste. "Great Fleas Have Little Fleas" (animal parasites) begins with the gruesome account of a college initiation where two trichinosis deaths occurred after the neophytes had to eat "human flesh" (raw pork). The concluding sentence states, "This parasite . . . is today inflicting an incurable disease on from 10 to 25 million Americans." *Trichinella* may be infesting millions but not causing "incurable disease," a statement which, as a sequel to its preceding story seems especially unfortunate.

The very commendable and generally successful attempts to simplify termi-

nology and interpret science result in other inaccuracies.

As the book is evidently designed to recruit "medics" and their kin, even quotation marks cannot excuse the use of "ptomaine poisoning." Also, referring to diphtheria vaccine will harass future bacteriology and public health instruction. So will the statement (page 2) that "... germs are weakened every time they pass through a body that has good resistance to them. A germ that has passed through a highly resistant body is like a wounded soldier who cannot put up much of a fight." Another oversight (page 186) is omission of proteins from the necessary "chemical ingredients" foods.

Erroneous impressions are also given regarding some health department activities. Page 24 states that "... all persons who handle food in public places have to pass a medical examination. . . ." The same sort of health department must be envisaged on page 197, "... every public-health department sends out tons of educational material." Unfortunately, too many people gauge public health success by the volume of futile food handler examinations and even some health departments evaluate their program of public health education on a "tonnage" basis.

In the broad field covered by this book, inaccuracies are inevitable. Despite these criticisms, it should be very useful in high school and junior college libraries for reference and even assigned reading. However, the school physician or school nurse should first edit it with appropriate marginal notations. A few words with the classroom teacher would also be helpful. CHARLES E. SMITH

From Infancy Through Childhood—By Louis W. Sauer, M.D., Ph.D. New York: Harper, 1942. 200 pp. Price, \$2.00.

Here is another concise, well arranged and practical handbook for

parents which answers the questions most frequently raised in the care of babies and young children. It includes up-to-date material on vitamins and balanced diets and on the various immunization procedures. It is hopeful to find in the middle of this helpful volume such an excellent chapter on Mental Health. No consideration of child health today can overlook the importance of proper habit training. Dr. Sauer recognizes the advantages of the Nursery School, but warns against certain inherent dangers such as exposure to the communicable diseases.

The chapters on the prematurely born infant and the adopted child are timely and well written. The value of this book has been enhanced by excellent photographic illustrations, an appendix covering accidents, definitions of terms, and a complete index. The usual tables and charts on heights and weights are included. The publishers are to be congratulated upon the printing and general make-up of the volume.

RICHARD A. BOLT

Tuberculosis in Industry—Report of the Symposium Held at the Saranac Laboratory for the Study of Tuberculosis, Saranac Lake, N. Y., June 9-14, 1941. New York: National Tuberculosis Association, 1942. 374 pp. Price, \$3.00.

The 1941 sessions of the Symposium were devoted exclusively to tuberculosis in industry. After brief statements by Dr. Leroy U. Gardner on sources of infection, pathology, diagnosis, and treatment of pulmonary tuberculosis, the connection between the occurrence of this disease and various occupations was discussed by members of the Symposium. Emphasis on industrial health and employer responsibility, enforced by compensation laws, has focused attention on occupation as a cause of disease. It is no longer popular to think first of overcrowding, poor housing.

dietary deficiencies, and physical or mental strain as accessory causes of a newly discovered case of tuberculosis. Some specific factor like an irritating gas or a hot or humid atmosphere in workshops now comes to mind as the most probable cause.

Reduction in the incidence of tuberculosis among the general population has been paralleled in industry. In 1911 tuberculosis of the respiratory system was the first cause of death among industrial wage earners insured by the Metropolitan Life Insurance Company, accounting for more than 20 per cent of the deaths. Today it is fifth in importance and accounts for $6\frac{1}{2}$ per cent of the deaths among these workers. A study by the National Institute of Health of data from 49 mutual sick benefit associations showed a steady downward trend in deaths from tuberculosis from 1925 to 1939.

Members of the Symposium were in agreement on the following points: There can be no tuberculosis without tubercle bacilli; the opportunities for infection vary widely in different communities in different social strata in those communities; the prevalence of disease is not uniform; the source of infection is invariably another tuberculous individual; transmission of infection is usually in the immediate vicinity of the open carrier; most clinically significant tuberculosis is the result of reinfection although we recognize that sometimes primary tuberculosis may give rise to such disease.

The all-embracing environmental factor, designated as the "standard of living," was accepted as significant in the etiology of tuberculosis. It was concluded that of all the accessory environmental factors peculiar to industry only exposure to free silica is acceptable without challenge. Of the dusts, only those high in free SiO_2 are known to alter appreciably susceptibility to tuberculosis.

It was concluded that the basis of control is education and prevention, and the essence of prevention is discovery of the case and its prompt treatment.

R. R. SAVERS

The Doctors Mayo—By Helen Clapesattle. Introduction by Dr. Guy Stanton Ford. Minneapolis: University of Minnesota Press, 1941. 864 pp., 64 ill. Price, \$3.75.

Contemporary or near-contemporary biography must of necessity be an *ex parte* statement. It cannot afford to indulge in detached weighing of evidence for or against the historical importance of its subject; nor is there the impulse to do so. It exists because a man—or, as in the present instance, a closely-knit group of men—has made sufficient impact on his time to be thought worthy of the record. The author must be, by definition of his purpose, an enthusiast. The one essential quality of such a biography, therefore, is success in portraying the color of the subject rather than his accomplishments.

The present work, in so far as it represents biography, is curiously mixed when measured by this standard. The first portion dealing largely with the older Dr. Mayo, is extraordinarily successful. Evidencing wide research, it presents an exciting picture of a pioneer civilization, in addition to a living portrait of a man. In the second portion, however, dealing with the sons, the authoress has allowed great accomplishments to mechanize the portrait. Somehow the Mayo brothers fail to emerge as the living characters they were. Possibly this is due in part to what appears to be an intent to steer away from the domestic scene wherein the color of men may often be most readily appreciated. If this course was for obvious reasons necessary, it is perhaps too bad that publication could not have been delayed until all the pigments could be employed.

One regrets a little the third portion of this volume, which consists of a too detailed description of the Mayo Clinic and Foundation, their origin, development, and organization, together with accounts of the more important medical contributions emanating therefrom, all told in a tone of somewhat fulsome praise.

EDWIN P. LEHMAN

Public Works Engineers' Yearbook 1942—*Chicago: American Public Works Association*, 1942. 387 pp. Price, \$3.50.

The 1942 edition of the *Public Works Engineers' Yearbook* presents an excellent overall picture of current problems in the public works field. The volume comprises the papers presented at the annual Public Works Congress which cover the major activities in this broad field of public endeavor, supplemented by timely material especially prepared by outstanding authorities. There is also included a report of the business proceedings of the association and its membership roster. The book's usefulness is increased by an index.

Organized under functional headings for ready reference, this edition of the *Yearbook* contains more than 30 authoritative articles on such subjects as:

Public Works Problems in Defense Areas
Public Works in the Post Defense Period
Highway Transportation in Wartime
Operating Results in the Combined Disposal of Garbage and Sewage

Current Developments on Brick Pavements, Concrete Paving, and Asphalt Paving
Factors Governing the Selection of the Type of Sewage Treatment

Recommended Practice for Street Lighting
Impact of Defense Activities upon West Coast Paving Practices

Civilian Protection: Plans, Organization, and Facilities

The Army Construction Program and Municipal Cooperation

Progress in Airport Development
Review and Current Status of Road and Street Stabilization.

Current Trends in Sewage Disposal

Management of Public Works Equipment and Supplies

Effect of Wartime Conditions upon Public Works in England

It will be seen from the list of articles presented that emphasis has been placed on defense. In addition, there are included a bibliography on field engineering and a series of articles on public works practices in New Orleans.

Throughout the *Yearbook*, both the administrative and technical aspects of the problem are discussed. Governmental administrators, research bureaus, libraries, and others, as well as public works engineers and officials will find a wealth of information in this important reference volume.

C. P. STRAUB

Manual for Managers of Rural and Other Small School Lunch Rooms—*Cleveland: The Ohio Dietetic Association (1001 Huron Road)*, 1942. 226 pp.

This *Manual*, prepared and published by the Ohio Dietetic Association, is especially timely since federal government agencies and state and local nutrition committees are promoting the expansion of hot lunch programs in rural areas. This book recognizes that many who are thus put in charge of the lunch room have not had adequate training or experience in this work, and that they need concrete, practical guidance. The basic principals of child feeding that are illustrated are in accordance with up-to-date nutritional data. The progressive view of "education through the school lunch" is present all through the book. It recognizes the need to train children in proper health habits, as well as to provide balanced meals.

There is adequate background information given for each phase of the work so that the inexperienced worker, after reading it, will be in command of a good working knowledge of the problems involved. The suggested

forms for keeping records will orientate the novice and give valuable suggestions to the experienced. The recipes are set up clearly in a simplified form for quantities of 12, 25, and 50, which may easily be multiplied for greater amounts. All food workers should find the Tables of Weights, Measurements, and Symbols used in Recipes of great help, and the Tables of Some Common Food Measurements, and the Average Number of Servings Obtained from Common Staples, will be great time savers. The *Manual* is timely as well as efficient, and it should prove valuable to the individual managers of rural and other small lunch rooms, as well as expedite the expansion of the hot lunch program in these areas.

CONSTANCE C. HART

Manual for Teaching Midwives—
By Anita M. Jones, R.N. Bureau Publication No. 260, U. S. Department of Labor, Children's Bureau. Government Printing Office, Washington, 1941. For sale by the Superintendent of Documents, Washington, D. C. Price, \$.30.

Recently published by the Children's Bureau of the U. S. Department of Labor is this *Manual*. Its purpose is to present a well planned course of twenty classes, demonstrations, and practice periods for the instruction of midwives. Its object is to instruct the poorly trained and often uneducated midwife "to use aseptic technique; never to interfere with the delivery of the baby; and to call the doctor at the first sign of danger." The author, herself a nurse-midwife, obviously is well acquainted with the type of individual to whom this instruction should go.

Accordingly, the subject material has been simplified so far as possible and has been expressed in language suitable to the medically untrained. Of particular merit are many simple diagrams illustrating labor, delivery, etc., as it concerns the midwife, and also others

for the construction of materials necessary to her and her patient so that parturition may be conducted in as safe a manner as possible.

The manual is to be recommended freely to the health departments of those states in which many deliveries must still of necessity be accomplished by midwives rather than physicians. It should also be required reading for the public health nurse in rural areas who is frequently called upon to assist the local doctor, or who, in case of emergency, may have to attend the patient herself.

C. H. PECKHAM

A Primer on the Prevention of Deformity in Childhood—
By Richard Beverly Raney, B.A., M.D. in collaboration with Alfred Rives Shands, Jr., B.A., M.D. Elyria, Ohio: National Society for Crippled Children of the United States of America, Inc., 1941. 188 pp. Price, \$1.00.

This book, as its name implies, is concerned with the various deformities that may arise in childhood, their origin and prevention. It is designed not for orthopedic surgeons, but for the many people who are interested in crippled children and assist in their care—nurses, social workers, physicians who have had little training in this field, as well as lay-folk.

The style of the book is simple, readable, and leads to easy understanding. Eighty-seven well chosen drawings assist greatly in the presentation of the material. A glossary is appended to aid those who have difficulty with the more complicated medical terms.

The authors are to be congratulated on giving us a book which contains an amazing amount of information and yet is presented in such a fashion that those without any considerable knowledge of the subject may understand and appreciate it. This book is a valuable addition to any library.

WILLIAM T. GREEN

Food Values in Shares and Weights—By *Clara Mae Taylor*. New York: Macmillan, 1942. 92 pp. Price, \$1.50.

This little book is a timely help when everyone is showing a new interest in nutrition and trying to use the most adequate diet. It not only gives the approximate recognized nutrients needed, but also tells which foods will supply them.

The real feature of the book is in the fact that it gives a quick method of evaluating diets, which is set forth in tables that show the amounts of the nutritive essentials in both shares and weights. With the share system, which has been described in earlier nutrition publications by the late Dr. Mary Swartz Rose, it is possible to show very concretely the contribution of each food stuff that the various articles of food make. The book contains graphs which illustrate this for men and women of various degrees of activity and also for the child at different stages of its growth.

The tables have been worked out according to the new recommended daily allowances suggested and adopted by the Committee on Foods and Nutrition of the National Research Council in May, 1941.

The book will be valuable to teachers of nutrition and also offer a very definite help to public health nurses as well as to the housewife who wants to help herself. MARY AGNES DAVIS

Biology for Better Living—By *Ernest E. Bayles and R. Will Burnett*. New York: Silver Burdett, 1942. 754 pp. Price, \$2.28.

This biology for the secondary school reflects an increasing tendency to include material in the form of personal and public hygiene in a course designed to introduce the student to the nature of living things. One of the eight units in this book is devoted to Personal and

Social Health, with an allotment of one hundred pages. Other units deal with the nature of plants and the use of land, adaptation, the use of food in the body, plant and animal behavior, evolution, inheritance, and the conservation of biologic wealth.

The book is clearly and simply written, well illustrated, and attractive in format. C. E. TURNER

Textbook of Clinical Parasitology—By *David L. Belding, M.D.* New York: Appleton-Century, 1942. 890 pp. Price, \$8.50.

The present war has stimulated interest in the prevention, recognition, and treatment of parasitic diseases. It is, therefore, desirable now and in the post-war period to have available accurate knowledge of the clinical aspects and recent advances in the treatment of these diseases. This need is well met in this book. The essential medical aspects of protozoölogy, helminthology, and entomology are practically combined in a single volume. The material is clearly presented, and such matters as life cycles are enhanced by diagrammatic representation. On the whole, the text is profusely illustrated. In addition there are useful tables facilitating reference to geographic distribution, principal pathology, insect vectors, symptomatology and treatment of parasitic diseases. The technical supplement is quite complete and up to date.

Treatment is discussed in general under each disease but specific directions are found in a separate section toward the end of the book. To this reviewer it would seem to be more advantageous to have a complete chronological discussion with specific directions, dosage, etc., under each subject rather than to have to interrupt one's reading to refer to another section in the book. In the discussion of amebiasis, reference is not made to Dio-

doquin which apparently has a definite place in the therapy and possibly the prevention of that disease.

However, these are relatively minor points in a single volume which seems very useful for the practitioner, the student, the public health man, and the field worker.

HARRY MOST

New Health and Growth Series—
By *W. W. Charters, Ph.D., Dean F. Smiley, M.D., and Ruth M. Strang, Ph.D.* New York: Macmillan, 1941.

Grade 1.	All Through the Day	178 pp.	Price \$.72
" 2.	Through the Year	180 pp.	" .80
" 3.	Health Secrets	242 pp.	" .84
" 4.	Healthful Ways	246 pp.	" .84
" 5.	Let's Be Healthy	278 pp.	" .88
" 6.	Habits, Healthful and Safe	277 pp.	" .92
" 7.	Growing Up Healthy	277 pp.	" .92
" 8.	A Sound Body	310 pp.	" .96
" 9.	Health in a Power Age	333 pp.	" 1.20

This is a delayed review of one of the best of the sets of health readers to appear during the past year. The series is such a complete revision of the original that comparisons with the earlier set are pointless.

The readers, particularly for the first four grades, are outstanding for their simplicity of statement, their interesting stories of Bobby and Nancy and their friends, and the intriguing photographs which illustrate everything from lovely Nancy in the bathtub to pictures of foods from which the reader is asked to choose a good luncheon menu. Especially well done are the narratives pointing up desirable personality habits. The authors have refrained from moralizing, and delightful stories for teachers and pupils alike are the result.

The books for the upper grades introduce materials on both structural and functional aspects of major body organs and systems. Emphasis, how-

ever, is placed on the relation of this knowledge to activities of boys and girls of the various age levels.

As to the form: each book from first grade through ninth calls for participation by the child. There are things to do, problems to work on, and questions which test how accurately the reading has been done. Beginning with the third grade reader a glossary is included and diagrams are introduced to aid the photographs in illustrating the text. Reading references enlarge the scope of the readers for junior high school level.

The photographs in this series, however, are the striking feature. Not only do they represent modern photography at its best in illustrating the text, but they are used consistently as teaching devices. Photographs offer puzzles to solve; games to play; tests of whether what is read is understood. These are new and delightful uses of pictures. The pictures, moreover, illustrate health without a word of text. This is the effect of page after page of pictures of fine healthy children having fun with life.

Of special note is the adequate treatment given the subject of nutrition on every grade level. Nutrition has been related to life activities and the growth and development of the body. Facts about foods appear in pictures and words in the first four grades; reports of experiments and tables of food values appear in the next four grades, with the story of digestion and its relation to eating habits presented in Grade 8, and the public health aspects of nutrition coming in Grade 9. It is a splendid sequence of sufficient interest even to a slightly fatigued campaigner in the present national nutrition program.

DOROTHY B. NYSWANDER

BOOKS RECEIVED

- PREVENTIVE MEDICINE IN MODERN PRACTICE.** Edited by Committee on Public Health Relations of The New York Academy of Medicine. New York: Hoeber, 1942. 851 pp. Price, \$10.00.
- FIRST AID PRIMER.** By Hermann Leslie Wenger and Eleanor Sense. New York: Barrows, 1942. 104 pp. Price, \$1.00.
- THE MODERN ATTACK ON TUBERCULOSIS.** By Henry D. Chadwick and Alton S. Pope. New York: Commonwealth, 1942. 95 pp. Price, \$1.00.
- HEALTH EDUCATION OF THE PUBLIC.** By W. W. Bauer and Thomas G. Hull. 2d ed. Philadelphia: Saunders, 1942. 315 pp. Price, \$2.75.
- HEREDITY, FOOD, AND ENVIRONMENT IN THE NUTRITION OF INFANTS AND CHILDREN.** By George Dow Scott. Boston: Chapman & Grimes, 1942. 778 pp. Price, \$5.00.
- AMERICA'S NUTRITION PRIMER.** By Eleanor Sense. 4th ed. New York: Barrows, 1941. 95 pp. Price, \$1.00.
- THE PUBLIC HEALTH NURSING CURRICULUM GUIDE.** Prepared by Joint Committee of the National Organization for Public Health Nursing and the United States Public Health Service. New York: National Organization for Public Health Nursing, 1942. 206 pp. Price, \$2.00.
- A COOK BOOK FOR NURSES.** By Sarah C. Hill. rev. ed. New York: Barrows, 1937. 74 pp. Price, \$1.25.
- PEOPLE ARE IMPORTANT.** By Floyd L. Ruch, Gordon N. Mackenzie, and Margaret McClean. Chicago: Scott, Foresman & Co., 1941. 283 pp. Price, \$1.32.
- SEX EDUCATION IN HIGH SCHOOLS.** By John Newton Baker. New York: Emerson, 1942. 155 pp. Price, \$2.00.
- THE DYNAMIC STATE OF BODY CONSTITUENTS.** By Rudolph Schoenheimer. Harvard University Monograph in Medicine and Public Health, Number 3. Cambridge: Harvard University Press, 1942. 78 pp. Price, \$1.75.
- ALCOHOL EXPLORED.** By H. W. Haggard and E. M. Jellinek. Garden City: Doubleday, Doran, 1942. 297 pp. Price, \$2.75.
- THE SCIENCE OF HEALTH.** By Florence L. Meredith. Philadelphia: Blakiston, 1942. 427 pp. Price, \$2.50.
- THE SANITARY INSPECTOR'S HANDBOOK.** By Henry H. Clay. 5th ed. London: Lewis, 1942. 534 pp. Price, \$5.25.

- PROCEEDINGS OF THE EIGHTH AMERICAN SCIENTIFIC CONGRESS.** Vol. I, Organization, Activities, Resolutions, Delegations. Washington: Department of State. 1941. 539 pp.
- CHRONIC PULMONARY DISEASE IN SOUTH WALES COALMINERS.** 1—Medical Studies. London: H. M. Stationery Office, 1942. 222 pp. Price, \$3.00.
- WITH THIS RING.** By Ethel Miller Nash. New York: Association Press, 1942. 112 pp. Price, \$1.50.
- DR. BARD OF HYDE PARK.** By J. Brett Langstaff. New York: Dutton, 1942. 365 pp. Price, \$3.75.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

New Index of Illness—Lest you may have missed this inconspicuous item, your attention is called to the table that inaugurates a monthly report on admission rates to hospitals under the various Blue Cross plans.

ANON. Incidence of Hospitalization, April, 1942. Pub. Health Rep. 57, 22:842 (May 29), 1942.

Care of Premies—Successful premature nursing care as carried on in a Michigan maternity hospital is described. Survival rates prove that good care pays.

BARNES, A. C., and WILLSON, J. R. Care of the Newborn Premature Infant. J.A.M.A. 119, 7:545 (June 13), 1942.

Barnyard Note—From a wide application of neutralization tests, it appears that, in one western valley region where equine encephalitis occurs in annual epidemics, the domestic fowls serve as reservoirs for infection of mosquitoes. The proportion of susceptible horses that become infected is very high.

HAMMON, W. McD., *et al.* A Large-Scale Serum-Neutralization Survey of Certain Vertebrates as Part of an Epidemiological Study of Encephalitis of the Western Equine and St. Louis Types. J. Immunol. 43, 5:75 (May), 1942.

Simple Senile Deterioration—Are you interested in the problem of aging? Either from your own, or the standpoint of your wartime job? Then you'll find much quotable material here, such as "the earliest symptom of senility is an inability to find any good in the present state of affairs and a tendency to glorify the past." There is much scientific discussion, too, and an excellent bibliography.

KORENCHEVSKY, V. The War and the Problem of Aging. J.A.M.A. 119, 8:624 (June 20), 1942.

"Oh Wad Some Power the Giftie Gie Us" . . .—It is always a salutary experience to see ourselves as we are seen by other eyes. This British professor of preventive medicine tells his fellow medical officers what he saw of the American scheme of civilian defense. It is full of delightful comments, some typically British in their understatement, as for instance, "The leadership of the health officer in civil defense is not therefore regarded as a matter of course . . ." He is very charitable in his criticism of our floundering efforts to build a defense organization.

MACKINTOSH, J. M. Civil Defense in the United States. Pub. Health. 55, 9:163 (June), 1942.

Still the Costliest Health Hazard—Establishing clinics and padlocking houses of prostitution do not constitute an effective V. D. control plan. The social protection program of the Federal Security Agency looks to a liaison between police and welfare agencies, adequate detention facilities, vocational training of offenders and supervision of employment of girls.

McNUTT, P. V. The Federal Fight Against Venereal Disease. J. Social Hyg. 28, 3:117 (Mar.), 1942.

"Down in the Cellar, by the Jail"—"Defiled health departments I have known" would be a good title for this incredible tale, incredible if one were not aware of the truthfulness and the probity of the narrator. Some practical solutions are proposed for this inexcusable state of affairs.

MOUNTIN, J. W. Housing of Health Departments. *Pub. Health Rep.* 57, 21:781 (May 22), 1942.

Pattern for Safe Water Supplies—Just which state agencies perform what sanitary control of water supplies and sewage disposal systems are tabulated in this report upon the sanitary services of the several state health departments.

MOUNTIN, J. W., and FLOOK, E. Distribution of Health Services in the Structure of the State Government. *Pub. Health Rep.* 57, 24:885 (June 12), 1942.

V. D. Case Finding—Here you may read all the details by which the epidemiology of the venereal diseases is carried on in one hospital clinic. Given a competent social service it is possible to obtain the names of extra-marital contacts of new cases and these may be induced to submit to examination and treatment. This story needs constant repetition; for as yet it is one of the sadly neglected fields in public health administration.

SWEENEY, A. Studies in the Epidemiology of Syphilis. *Ven. Dis. Inform.* 23, 4:137 (Apr.), 1942.

Worker Fitness in the National Crisis—Shortcomings of the industrial health situation are surveyed to present a disquieting picture of their inadequacies. A convincing case is made for the need of immediate strengthening of the industrial health services.

TRASKO, V. M., and BLOOMFIELD, J. J. An Analysis of Industrial Hygiene Activities in State and Local Health Departments, 1940-41. *Pub. Health Rep.* 57, 23:853 (June 5), 1942.

"Digging for Mrs. Miller"—How the English have organized first aid and emergency treatment is most graphically described by one who was there. Certainly every American health worker ought to be informed about what England has proved in the fire of its dreadful experience.

WILLIAMS, H. Air Raid Medical Administration in England. *J.A.M.A.* 119, 7:540 (June 13), 1942.

Preliminary Program of the Scientific Sessions of the 71st Annual Meeting of the American Public Health Association, and Meetings of Related Organizations, and of the Ninth Institute on Public Health Education

St. Louis, Mo.

October 24-30, 1942

THE Annual Meeting Program Committee offers a preview of the content of scientific sessions planned in connection with the 71st Annual Meeting in St. Louis, Mo. In many instances, sessions are complete. In others, places are purposely left open for important matters which may develop before October. Inaccuracies and omissions are to be expected and it is hoped they will be excused. The professional affiliations and addresses of speakers are not given, but a complete index to participants will be published in the final program which will be distributed to all delegates at the Registration Desk, Auditorium. Registration headquarters will be opened at 9:30 A.M. on Sunday, October 25.

Presiding: CHARLES C. WILSON, M.D., *Chairman.*

A PUBLIC PROGRAM OF OUTPATIENT SERVICES FOR CHILDREN
WITH CEREBRAL PALSY

Panel Leader: WINTHROP PHELPS, M.D.

Participants to be announced.

WEDNESDAY, 9:30 A.M.

LABORATORY, ENGINEERING, AND EPIDEMIOLOGY
SECTIONS*Joint Session—Assembly Room 1, Auditorium**Presiding:* JAMES GIBBARD, J. LLOYD BARRON, C.E., and ALTON S. POPE, M.D.

SYMPOSIUM ON WATER AND MILK-BORNE INFECTIONS

The Hypothetical Relationship of Water Supplies to Poliomyelitis.
KENNETH F. MAXCY, M.D.Safety of the Milk Supply and Reduced Mortality. HERMAN N. BUNDE-
SEN, M.D., and PAUL F. KRUEGER.Brucellosis: Consideration of Its Epidemiology, Diagnosis and Control.
CARL F. JORDAN, M.D., I. H. BORTS, M.D., D. M. HARRIS, M.D., and J. R.
JENNINGS, C.E.Field and Laboratory Studies on Water-borne Gastroenteritis. RALPH
E. WHEELER, M.D., and ROY C. AVERY.

LABORATORY

*Second Session—Committee Room C, Auditorium**Presiding:* PEARL L. KENDRICK, Sc.D.The Isolation of *Neisseria flava* from the Genitourinary Tract of
Three Patients. CHARLES M. CARPENTER, M.D.A Report on Methods of Transmitting Material to a Laboratory for
Gonococcus Cultural Studies. OSCAR F. COX, M.D., and MARY V.
McDERMOTT.Reversibility of Sensitization of Erythrocytes. G. M. KALMANSON, Ph.D.,
and J. J. BRONFENBRENNER, Dr.P.H.Four Years' Use of the Kahn Presumptive Test as a Screening Agency
in the Serology of Syphilis. E. L. WEBB.Studies on the Kahn Verification Test. ELIZABETH B. McDERMOTT, JACOB
ADLER, M.D., STANLEY MARCUS, ELLA BRANDON, HOWARD J. NUNES, and
REUBEN L. KAHN, Sc.D.The Effect of Age of Specimens on the Results of Serological Tests
for Syphilis. ANNE KIMBALL, Ph.D.

ORAL HEALTH GROUP

*First Session—Committee Room 3C, Auditorium**Presiding:* ALLEN O. GRUEBBEL, D.D.S., *Chairman.*

WEDNESDAY, 9:30 A.M.

FOOD AND NUTRITION

Third Session—Committee Room 3C, Auditorium

Report of the Coördinating Committee. *Chairman*, F. C. BLANCK, PH.D.

Report of the Committee on Microbiological Examination of Foods.
Chairman, HARRY E. GORESLINE, PH.D.

Report of the Committee on Nutritional Problems. *Chairman*, E. V. MCCOLLUM, PH.D.

Report of the Committee on Foods (Except Milk). *Chairman*, BERNARD E. PROCTOR, PH.D.

Report of the Joint Committee on Analyzing Frozen Desserts. *Chairman*, FREDERICK W. FABIAN, PH.D., and *Chairman*, FRIEND LEE MICKLE, SC.D.

Report of the Committee on Food Utensil Sanitation. *Chairman*, GEORGE J. HUCKER, PH.D.

Report of the Committee on Assay of Foods. *Chairman*, CARL R. FELLERS, PH.D.

Report of the Committee on Membership and Fellowship. *Chairman*, RACHEL L. REED.

PUBLIC HEALTH EDUCATION

Second Session—Assembly Room 3, Auditorium

Presiding: D. OBERTEUFFER, PH.D.

HEALTH EDUCATION, WAR AND DEFENSE

First Aid Instruction in Relation to Health Education. ALBERT McCOWN, M.D.

Health Education in Extra-Cantonment Zones. Speaker to be announced.

Health Education in the National Nutrition Program. Speaker to be announced.

Discussion.

WEDNESDAY, 11:30 A.M.

Second General Session—Opera House, Auditorium

Presiding:

WAR AND THE HEALTH DEPARTMENT

Across the Nation. Speaker to be announced.

In an Eastern City. Speaker to be announced.

In a Western County. Speaker to be announced.

WEDNESDAY, 12:30 P.M.

INDUSTRIAL HYGIENE

Luncheon Session—Crystal Room, Hotel New Jefferson

Address: A representative of Great Britain.

Report of the Committee on Skin Irritants. *Chairman, LOUIS SCHWARTZ, M.D.*

Report of the Committee on Ventilation and Atmospheric Pollution. *Chairman, EMERY R. HAYHURST, M.D.*

Report of the Committee on Standard Methods for the Examination of Air. *Chairman, EMERY R. HAYHURST, M.D.*

Report of the Committee on Lead Poisoning. *Chairman, ROBERT A. KEHOE, M.D.*

Report of the Committee on Pneumoconiosis. *Chairman, R. R. SAYERS, M.D.*

Report of the Committee on Industrial Anthrax. *Chairman, HENRY FIELD SMYTH, M.D.*

Report of the Committee on Volatile Solvents. *Chairman, HENRY FIELD SMYTH, JR., M.D.*

AMERICAN SCHOOL HEALTH ASSOCIATION AND ORAL HEALTH GROUP

Joint Luncheon Session—Roof Garden, Hotel Statler

Presiding: ARTHUR R. TURNER, M.D., and ALLEN O. GRUEBBEL, D.D.S.

What Is the Private Dentist's Part in the School Health Program?
GEORGE M. WHEATLEY, M.D.

FOOD AND NUTRITION

Luncheon Session—Ivory Room, Hotel New Jefferson

Program to be announced.

JOHNS HOPKINS UNIVERSITY ALUMNI

Luncheon Session—Room 1, Hotel New Jefferson

WEDNESDAY, 2:30 P.M.

PROFESSIONAL EDUCATION

Special Session—Assembly Room 2, Auditorium

Presiding: WILLIAM P. SHEPARD, M.D., Chairman, Committee on Professional Education.

Program to be announced.

WEDNESDAY, 2:30 P.M.

LABORATORY

*Third Session—Assembly Room 1, Auditorium**Section Business.*

Report of the Standard Methods Committee for the Examination of Disinfectants and Antiseptics. *Chairman*, STUART MUDD, M.D.

Germicidal Vapors as a Means of Disinfection of Air. O. H. ROBERTSON, M.D.

Ultra-Violet Irradiation as a Means of Disinfection of Air. ALEXANDER HOLLAENDER, PH.D.

Relation of Length of Carbon Chain to the Primary and Functional Toxicities of Alcohols. HENRY WELCH, PH.D., and G. G. SLOCUM, PH.D.

Changes in the Bacterial Cell Brought About by the Action of Germicides as Demonstrated by the Electron Microscope. STUART MUDD, M.D.

Variations in Phenol Coefficient Determinations of Certain Disinfectants. CHARLES M. BREWER, PH.D.

Bacterial Contaminations in Sulfonamide Products. C. VIRGINIA FISHER, PH.D., N. J. ACCOUSTI, and MARVIN R. THOMPSON, PH.D.

PUBLIC HEALTH EDUCATION AND PUBLIC HEALTH
NURSING SECTIONS AND AMERICAN SCHOOL
HEALTH ASSOCIATION

Joint Session—Opera House, Auditorium

Luncheon Session—Ivory Room, Hotel New Jefferson

FRIDAY, 2:30 P.M.

FIFTH GENERAL SESSION

Assembly Room 1, Auditorium

HIGHLIGHTS OF THE 71ST ANNUAL MEETING

A SUMMARY OF THE SCIENTIFIC SESSIONS

Presiding: REGINALD M. ATWATER, M.D.

Panel Participants:

A spokesman from each of the ten Sections.

THE TECHNICAL EXHIBITS AUDITORIUM

EXHIBITORS in the Twenty-Fourth Health Exhibit, sponsored by the American Public Health Association in connection with its 71st Annual Meeting, describe the exhibits they are preparing for the information of delegates as follows:

A. S. ALOE COMPANY

ST. LOUIS, MO. Nos. 78 AND 79
Laboratory apparatus and equipment of interest to the Public Health and allied worker. Modern equipment for the preparation of human blood plasma and its administration will be shown. The new Chapple Infant Incubator, having complete environmental control, will be on exhibit and will be demonstrated. New and recent scientific apparatus, serological water baths, apparatus for industrial hygiene tests—such as equipment for the determination of lead in blood and urine—will also be presented.

AMERICAN BOTTLERS OF CARBONATED BEVERAGES

WASHINGTON, D. C. Nos. 23 AND 24
The glass-paneled Field Laboratory on display here is the motorized unit of the American Bottlers of Carbonated Beverages, national association of the soft drink industry. Pioneer in its field, the unit carries sufficient chemical, bacteriological, and engineering apparatus to make specialized investigations and quality control tests on carbonated beverages in bottling plants throughout the United States. The Field Laboratory, in bringing its unique individual service to the bottlers, operates as an adjunct to the permanent laboratory of the association located in Washington, D. C.

AMERICAN CAN COMPANY

NEW YORK, N. Y. Nos. 59 AND 60
Convention delegates are cordially invited to visit Booths 59 and 60 where information is available concerning those aspects of commercially canned foods which are of particular interest to members of the American Public Health Association. The American Can Company's modern, single-service, paper milk container will also be featured.

THE BEST FOODS, INC.

NEW YORK, N. Y. No. 65
Booth 65 dramatizes the manufacture of Nucoa, the Modern Vegetable Margarine. The display features the elaborate testing carried on to maintain the uniform quality of Nucoa and its consistent Vitamin A potency of 9,000 USP units per pound. Highlighted also are the fine flavor and texture of Nucoa and the increasingly important place of fortified margarine in the national nutrition program.

THE BORDEN COMPANY

NEW YORK, N. Y. No. 3
The Borden Company will exhibit an attractive display of milk products. Convention delegates are invited to visit Booth 3 for nutrition material planned for practical use in both home and office.

CAMEL CIGARETTES—MEDICAL RELATIONS DIVISION

NEW YORK, N. Y. Nos. 34 AND 35
CAMEL Cigarettes will exhibit large detailed photographs of equipment used in comparative tests of the five largest

selling brands of cigarettes. These tests proved that CAMELS burn slower and contain less nicotine in the smoke than other cigarettes. Representatives will be available to discuss this research.

CARNATION COMPANY

OCONOMOWOC, WIS. Nos. 45 AND 46
In the Carnation Company exhibit in Booths 45 and 46 you will see a complete and dramatic presentation of the story of Irradiated Carnation Milk. Every operation in the processing—from farm to finished product—is performed in miniature before your eyes. You will enjoy this personally conducted tour through a Carnation evaporating plant.

CHURCH & DWIGHT CO., INC.

NEW YORK, N. Y. No. 47
Twenty-five years before the first meeting of The American Public Health Association, Church and Dwight Company pioneered in first producing Bicarbonate of Soda in the Western Hemisphere. For nearly a century, this company has endeavored to improve its product and make it available at low cost. Today, Arm & Hammer Bicarbonate of Soda, known generally as Baking Soda, can be found in nearly every household. The low cost, purity and availability of Arm & Hammer, and the fact it is approved as a dentifrice by the American Dental Association Council, are reasons so many Health Officers recommend it in their Dental Health Educational work.

CLAY-ADAMS COMPANY, INC.

NEW YORK, N. Y. No. 10
The Clay-Adams Company exhibit comprises three types of equipment.
• • • • • INSTRUMENTS AND SUPPLIES
• • • • • new cardboard slide
• • • • • blood and other
• • • • • 1 slides and cover
glasses, agglutination slides, slide boxes and specialties for microscopy.

EDUCATIONAL including anatomical charts and models, skeletons, Ayers and other obstetrical manikins, Chase Hospital Dolls.

MEDICAL AND SURGICAL SPECIALTIES including Caecoprene (synthetic rubber) catheters, drains, tubes, utility forceps, and Justrite Elastic Dressing.

THE COCA-COLA COMPANY

ATLANTA, GA. No. 37
If sugar rationing and other considerations permit, we plan to distribute Coca-Cola with our compliments to those attending the meeting.

THE CREAM OF WHEAT CORPORATION

MINNEAPOLIS, MINN. No. 53
THE CREAM OF WHEAT CORPORATION, Minneapolis, Minnesota (Booth 53), will exhibit Enriched 5-Minute "CREAM OF WHEAT." This improved cereal is completely cooked in five minutes and has been fortified with additional Vitamin B₁ (Wheat Germ and Thiamin), iron, calcium, and phosphorus.

R. B. DAVIS SALES CO.

HOBOKEN, N. J. No. 43

You are cordially invited to enjoy a drink of delicious Cocomalt at Booth 43. Cocomalt is a milk-fortifier, designed to be mixed with milk and served hot or cold. The food value and palatability of milk are considerably increased by the addition of this vitamin and mineral enriched food. Cocomalt is fortified with vitamins A, B₁ and D and minerals calcium, phosphorus and iron. Ask our representatives for reprints on our medical studies.

THE DICK X-RAY CO.

St. Louis, Mo. No. 4

We contemplate exhibiting at this meeting the Westinghouse Photo-Fluorographic x-ray unit, together with the Portable Dynex X-ray Generator. We will also show several types of Viewing equipment for this 35 mm. Photo-Fluorographic film. This unit is ideal for survey work in connection with the Public Health Service and many of the institutions and associations are using it for that purpose. Our representatives at the booth will explain this unit thoroughly to anyone who desires further information without any obligation on his part.

**DIFCO LABORATORIES
INCORPORATED**

DETROIT, MICH. No. 18

Exhibit of dehydrated culture media prepared according to the formulae of the American Public Health Association's "Standard Methods of Water Analysis" and "Standard Methods for the Examination of Dairy Products," as well as other media of particular interest in public health bacteriology.

Demonstration of Bacto-SS Agar, Bacto-MacConkey Agar and other media for isolation and identification of members of the typhoid-paratyphoid-dysentery group.

THE DIVERSEY CORPORATION

CHICAGO, ILL. No. 72

An educational display of real interest to all in attendance will be shown by The Diversey Corporation, Chicago, Ill. The principal section of the display consists of a three-panelled walnut background on which are mounted photographs and descriptive material showing the part played by Diversey Products and Diversey Service in maintaining public health standards. Every phase of modern cleaning and sterilization will be illustrated. The exhibit will be in charge of Mr. Lewis Shere, Vice-President.

EVAPORATED MILK ASSOCIATION

CHICAGO, ILL. No. 77

Of special interest to public health workers is the educational material of the Evaporated Milk Association. These publications are designed for use by public health departments in their nutrition programs, for maternal welfare centers, well-baby clinics and social service activities. Special materials are available on low-cost family feeding, prenatal, infant and pre-school child feeding, school lunches, and quantity food preparation. New material prepared in cooperation with the National Nutrition Program will be on display at our booth.

THE J. B. FORD SALES CO.

WYANDOTTE, MICH. No. 36

A complete line of Wyandotte Products for food and beverage plant sanitation will be on display.

Wyandotte Steri-Chlor, a chlorine powder, used in solution, for germicidal and deodorizing operations.

Wyandotte Dish and Glass Washing Compounds for hand and machine use in all kinds of water.

Wyandotte Detergent for washing painted surfaces, cleaning porcelain and floors.

Wyandotte Bottle Washing Materials for milk and beverage plants.

Cleaners for every requirement of the Dairy Industry—including smaller packages for dairy farmers.

Other Wyandotte Products for general cleaning in food manufacturing and canning plants, hospitals, schools, hotels, public buildings.

GERBER PRODUCTS COMPANY

FREMONT, MICH. No. 61

GERBER'S

The Gerber booklets for mothers and the professional filing cards showing nutritive values of average servings, will be available at booth 61. You will be interested in examining the complete line of Gerber Foods.

**THE GILLILAND LABORATORIES,
INC.**

MARIETTA, PA. No. 12

The Gilliland Laboratories will have on display at Booth 12 a complete line of Biological Products. This firm gives special attention to supplying Biological Products to State, City, and County Boards of Health, Hospitals and Institutions. The representative in charge of this exhibit will be pleased to answer any inquiries.

GRADWOHL SCHOOL OF LABORATORY TECHNIQUE

St. Louis, Mo. No. 2

This exhibit will show first a twenty-minute method of diagnosis of primary lesions of syphilis by frozen section and staining technique, thus obtaining a much higher percentage of accurate positives than the dark-field method; second, new facts on blood groups with demonstration of the Rh factor—an explanation of transfusion reactions, stillbirths, and miscarriages, and Erythroblastosis fetalis; and, third, motion picture of methods of teaching laboratory technique.

**HYGEIA, THE HEALTH
MAGAZINE**

CHICAGO, ILL. No. 51

The HYGEIA Exhibit will consist of a three panel display featuring a Blow-up of a HYGEIA cover design showing a baby in a bathtub. The other two panels contain editorial matter on HYGEIA. The whole material may be set up on a table 8 feet in length. A table at the front of the booth for issuing of sample copies and other material is used. The three panel display is lighted.

KELLOGG COMPANY

BATTLE CREEK, MICH. No. 73

Kellogg's ready-to-eat cereals play a vital part in good nutrition. They supply whole grain (natural or restored) values, as recommended by the United States nutrition food rules. Whole grain products or enriched white bread and flour or cereal products restored to their original whole grain nutritive value should be eaten daily.

Recent nutrition information is available at the Kellogg Booth. Also, ask for your set of medical reprints covering recent research with bran.

KIMBLE GLASS COMPANY

VINELAND, N. J. No. 13

Kimble Blue Line Exax and Normax Precision Rtested graduated ware and Kimble K Brand laboratory glassware and apparatus.

New. Brewer culture dish cover, an ingenious but simple device for easy cultivation of anaerobes without expensive equipment.

Especially featured. Bottles and other glass parts for preparation and injection of parenterals, particularly blood plasma. These are highly resistant to chemical attack, offering maximum assurance of unimpaired quality and clinical safety.

All material obtainable from laboratory supply houses.

LEDERLE LABORATORIES, INC.

NEW YORK, N. Y. Nos. 74, 75 AND 76

Sulfadiazine, the preferable sulfonamide of choice in pneumococcal infections, will be the focal point in Lederle's exhibit. This product was developed by its Sulfonamide Research Division of Lederle Laboratories. Animated charts dramatize the speed of recovery under the Sulfadiazine therapy in pneumonia and illustrate other points of advantages, i.e., low toxicity, infrequent nausea, etc. IMMUNIZATION is also illustrated, featuring Lederle's Pertussis Antigen; Smallpox Vaccine; Diphtheria Antitoxin; Tetanus Antitoxin; Scarlet Fever Streptococcus Immunizing Toxin. Another section is devoted to Tuberculin Patch Test (Vollmer). Representatives of Lederle's staff will be in attendance.

LILY-TULIP CUP CORPORATION

NEW YORK, N. Y., AND LOS ANGELES, CALIF. Nos. 54 AND 55.

Again this exhibit will feature information on the part that Lily-Tulip Cups and Containers play in the War program emphasizing the importance of the utmost in sanitation for industrial workers, school children, public use in restaurants, taverns, road stands, bars, military establishments, etc.

How Lily-Tulip Cups lower the incidence of disease in mass feeding.

J. B. LIPPINCOTT COMPANY

PHILADELPHIA, PA. No. 16

Of particular interest at the Lippincott exhibit are Zabriskie's "Mother and Baby Care in Pictures" and Hess and Lundeen's "The Premature Infant." Manzer's new book "Practical Sociology and Social Problems" will also be displayed. Meek's "Your Child's Development and Guidance Told in Pictures," Pillsbury's "Nursing Care of Communicable Diseases," Hasenjaeger's "Asepsis in Communicable Disease Nursing," and Ensworth and Greenwood's "Pneumonia and Its Nursing Care" are also important to Public Health Workers.

THE MACMILLAN COMPANY

NEW YORK, N. Y. No. 25

Of special interest to Public Health Workers, at the MACMILLAN Booth 25, will be the new book on RABIES, by Dr. Webster—"the most significant contribution to the study of rabies since the beginning of the century." Field workers and administrators alike look to COMMUNICABLE DISEASE CONTROL, by Anderson-Arnstein, and PUBLIC HEALTH ADMINISTRATION IN THE UNITED STATES, by Dr. Smithie, for answers on public health questions. Among other books will be the popular SO BUILT WE, by Mary S. Gardner, and THE PUBLIC HEALTH NURSE IN ACTION, by Marguerite Wales.

MERCK & CO., INC.

RAHWAY, N. J. No. 42

Chemotherapeutic agents of importance to members of the American Public Health Association will be on display at the Merck exhibit. Among these are: Vitamins—for the prevention and correction of nutritional deficiencies; Arspheamines—for the treatment of syphilis; Sulfonamides—for the treatment of gonococcal, pneumococcal, and other specific infections; Zinc Peroxide Special Medicinal—for the treatment of anaerobic wound infections; and Vinethene—for short anesthetics. Literature on these and other Merck products will be available at the Merck booth.

MINE SAFETY APPLIANCES COMPANY

PITTSBURGH, PA. No. 14

The M.S.A. booth will feature a complete line of personal and plant protective equipment: Gas-detecting and indicating instruments to include Carbon Monoxide Detector, Carbon Monoxide Indicator, Carbon Monoxide Alarm, Benzol Indicator, Model 1 and Model 2 Explosimeters, Explosionproof Combustible Gas Alarm, and dust sampling and counting instruments consisting of Midget Impinger, Electrostatic Dust and Fume Sampler, and Dust Counting Microscope. Dust and Mist Respirators, Cartridge Respirators, Gas Masks, Oxygen Breathing Apparatus, H-H Inhalator, Skullgard Protective Hats, First Aid Kits and Materials, Goggles, and Ear Defenders will be among the products displayed.

Both office and field representatives will be in attendance to demonstrate and discuss the equipment.

THE C. V. MOSBY COMPANY,
MEDICAL AND DENTAL
PUBLISHERS

ST. LOUIS, MO. No. 48

Public health workers attending the 71st Annual Meeting in St. Louis will find that time spent at the Mosby Booth 48, is time well spent. Among the books you're sure to find interesting are Top "Handbook of Communicable Diseases," Lynch "Communicable Disease Nursing," the new 6th edition Turner "Personal and Community Health," Turner-McHose "Effective Living," and Cameron "Bacteriology of Public Health." Whether you have a special book in mind or are "just looking" you're welcome at the Mosby Booth 48.

NATIONAL DAIRY COUNCIL

CHICAGO, ILL. No. 50

"Food for Victory" is the National Dairy Council animated, lighted exhibit. It presents the basic pattern for adequate daily meals as recommended by nutrition authorities. This exhibit bears the Seal of Acceptance of the Council on Foods and Nutrition, American Medical Association.

A life-size model of a homemaker points to the lighted, colored photographs of foods in the pattern. The side panel emphasizes the theme of nutrition and national Health: "Victory demands healthy Americans."

NATIONAL LIVE STOCK AND
MEAT BOARD

CHICAGO, ILL. No. 11

The exhibit of the National Live Stock and Meat Board will portray the rôle of meat as a source of protein, calories, minerals, and vitamins in the adequate diet. Literature showing the food value of meat and the place of meat in the National Nutrition Program will be available.

**NURSE PLACEMENT SERVICE,
INC.**

CHICAGO, ILL. No. 26

Anna L. Tittman, R.N., Executive Director, will be on duty throughout the meeting at Booth 26, which is set up as a temporary office with facilities for private interviews with employers of nurses and technicians (laboratory, x-ray, physiotherapy, etc.) and with nurses who desire guidance or placement in any of the fields of nursing except private duty.

OVAL WOOD DISH CORPORATION
TUPPER LAKE, N. Y. No. 49

The Oval Wood Dish Corporation will display in Booth 49, its complete line of Ritespoons and Riteforks—sanitary single service eating utensils. These sanitary single service utensils are made of pure, natural, White Birch wood, have the true shape of table silver, and are manufactured under strict sanitary control. They constitute the only real substitute for metalware in the mass feeding of defense workers in industrial plants throughout the United States, in Army Post Exchanges, Navy Yards, Shipyards, etc. Members of the A.P.H.A. are cordially invited to register for samples and literature.

PARKE, DAVIS & COMPANY

DETROIT, MICH. No. 39

A new type of Antitoxin is featured in the colorful display of Parke, Davis and Co. in Booth 39. Other outstanding contributions in the pharmaceutical and biological fields having particular interest in war time are also displayed.

Among the featured biological products are preparations for diagnosis, prophylaxis, immunization, and treatment.

You are cordially invited to visit this exhibit where you will find several members of Parke, Davis and Company's technical staff who will be pleased to explain the meritorious features of these and other products.

PET MILK SALES CORPORATION

ST. LOUIS, MO. Nos. 19, 20, 21 AND 22

An actual working model of a milk condensing plant in miniature will be exhibited by the Pet Milk Company in Booths 19, 20, 21, and 22. This exhibit offers an opportunity to obtain information about the production of Irradiated Pet Milk and its uses in infant feeding and general dietary practice. Miniature Pet Milk cans will be given to each physician who visits the Pet Milk Booth.

**PETROLAGAR LABORATORIES
INC.**

CHICAGO, ILL. No. 64

You are cordially invited to visit the Petrolagar exhibit where a new and enlightening story on Petrolagar, an aqueous suspension of mineral oil, will be related. Beautifully colored anatomical drawings and new literature may be had upon request from our professional representatives who will be in constant attendance.

POWERS X-RAY SERVICE

GLEN COVE, N. Y. No. 52

POWERS X-RAY SERVICE shows the rapid x-ray method and apparatus used by them for x-raying large groups of persons under the supervision of the medical profession. A demonstration of the comparative diagnostic clarity of the paper film and transparent base film is shown; also a typical roll of a hundred radiographs produced by this service.

All necessary equipment for making and processing the full size 14 x 17 inch radiographs is furnished as a part of the service, thus obviating any investment in chest apparatus for survey purposes.

PROCTER & GAMBLE—IVORY SOAP

CINCINNATI, OHIO No. 38

SIXTY-TWO YEARS' EXPERIENCE IN
MAKING MILD SOAP

What is soap's effect on the skin?

What makes a soap "mild"?

What are the new and accepted techniques for Testing Soap? With the appearance today of new studies of the functions of soap—in the field of public health and medicine—we believe the Ivory Soap exhibit will hold more than casual interest for professional public health workers. We cordially invite you to visit Booth 38 where a qualified member of Procter & Gamble's scientific staff will be glad to answer questions.

PHILIP MORRIS & CO., LTD., INC.

NEW YORK, N. Y. No. 44

Philip Morris & Company will demonstrate the method by which it was found that Philip Morris Cigarettes, in which diethylene glycol is used as the hygroscopic agent, are less irritating than other cigarettes. Their representative will be happy to discuss researches on this subject, and problems on the physiological effects of smoking.

RALSTON PURINA COMPANY

ST. LOUIS, MO. No. 15

Nutrition for National Defense being our theme, we will exhibit our famous whole grain cereal products; Ralston Hot Whole Wheat Cereal; Instant Ralston Hot Whole Wheat Cereal; Shredded Ralston, Bite Size Shredded Whole Wheat Cereal; Ry-Krisp, Whole Rye Wafer.

Our miniature cereal mill will demonstrate how a whole grain cereal is made. Research literature on nutrition and samples of various products will be distributed.

W. B. SAUNDERS COMPANY

PHILADELPHIA, PA. No. 9

The W. B. Saunders Company welcomes you to its exhibition, at Booth 9, of its complete line of books on Medicine, Nursing, and Health. Among these will be Bauer and Hull's Health Education, new edition; Bolduan's Public Health and Hygiene; Boyd's Preventive Medicine; Geiger's Health Officers' Manual; Conrad and Meister's Teaching Procedures in Health Education; Grant's new Nursing: A Community Health Service; Stokes' Clinical Syphilology; Stokes' Dermatology and Syphilology; Pelouze's Gonorrhea; and the new Duncan's Diseases of Metabolism.

SEALRIGHT COMPANY, INC.

NEW YORK, N. Y. Nos. 56, 57 AND 58

SEALTEST, INC.

NEW YORK, N. Y. Nos. 68 AND 69

The exhibit of the Sealtest System of Laboratory Protection explains the work of this organization in dairy products research and in production control of ice cream, milk and other dairy products. The activities of the Sealtest Laboratory Kitchen will also be featured. This is the Consumer Service division of the Sealtest System, promoting the use of dairy products in the home, with special emphasis on the nutritive value of these products.

SHARP & DOHME

PHILADELPHIA, PA. NOS. 40 AND 41
Sharp & Dohme will have a striking display featuring the Roper National Immunization Survey, products used for active immunization against diphtheria, whooping cough, typhoid fever, smallpox, tetanus, and scarlet fever, together with other biological and pharmaceutical products of interest to the Public Health physician. Another striking feature will be the display on "Lyovac" Normal Human Plasma. Capable, well-informed representatives will be on hand to welcome all visitors and furnish information on Sharp & Dohme products.

E. R. SQUIBB & SONS

NEW YORK, N. Y. NOS. 62 AND 63
The Squibb Exhibit, located in Booths 62 and 63, will utilize striking visual methods to convey pertinent information about a selected list of products of particular interest to workers in the field of Public Health. We hope that all visitors attending the American Public Health Association Convention will stop in at the Squibb Exhibit. Well informed representatives will be on hand to welcome visitors and to furnish detailed information on the products displayed.

THE STANDARD REGISTER
COMPANY

DAYTON, OHIO No. 71

UNITED FRUIT COMPANY

NEW YORK, N. Y. No. 70
At the United Fruit Company Booth 70, you will find an interesting display of the timely dishes which can be made with bananas and which can fit into the many phases of the present Public Health Program.
We will be pleased to have you register with us.

WALLACE & TIERNAN CO., INC.

NEWARK, N. J. NOS. 66 AND 67
The exhibit of Wallace & Tiernan Co., Inc. at the A.P.H.A. St. Louis meeting in October will feature emergency chlorination and include the W&T chlorination trailer, portable chlorinator and hypochlorinator. Photographs showing the havoc wrought in England on underground water mains as a result of bombing will be a part of our exhibit. A member of the W&T staff, thoroughly familiar with the priorities situation, will be on hand to answer questions in that connection.

Places of Scientific Interest in the Convention City

THE St. Louis Health Division is happy to invite the delegates of the American Public Health Association to visit the many places of scientific interest in St. Louis. Despite the fact that transportation facilities will not be available as in former years, for obvious reasons, an attempt will be made by the Arrangement Committee to carry out the wishes of the delegates regarding tours to certain places that they may be interested in. A brief description of the main places of scientific interest follows:

THE ST. LOUIS WATER WORKS

The construction of water works for the City of St. Louis was begun in 1829 by private parties under an exclusive franchise granted by the city. The city acquired ownership in 1835 and since that time the works have been in the process of improvement and enlargement almost continuously.

The location of the Intakes and Pumping Stations was changed in 1871 and again in 1892. In 1929, one hundred years after the first Water Works was started, a new plant was put in operation on the Missouri River at Howard Bend. At the Chain of Rocks the supply is pumped from the Mississippi River into six sedimentation basins having a capacity of about 200,000,000 gallons, where partial softening is effected by lime, and sedimentation is hastened by coagulation with sulfate of iron. Secondary coagulation and sedimentation in two additional basins are followed by filtration and sterilization with ammonium sulfate and chlorine. The rapid sand filters have a capacity of 160,000,000 gallons in 24 hours. The finished water flows by gravity through conduits to the High Service Pumping Stations located 3½

miles and 7 miles from the Chain of Rocks.

The Howard Bend Plant is located on the Missouri River at Howard Bend, about 16 miles from the city limits, and was built to augment the supply from the Chain of Rocks Plant. The same purification methods are followed as at the Chain of Rocks plant except that the supply passes through four basins for pre-sedimentation before the lime and iron sulfate are added and carbon dioxide can be added before filtration. The rapid sand filters have a capacity for 80,000,000 gallons per 24 hours. According to the latest annual report the total consumption for the fiscal year ending April, 1941, was 45,987,919,180 gallons and the average daily consumption was 125,994,299 gallons. A trip to the Water Works is scheduled.

THE DAIRIES

St. Louis is fortunate in having a Standard Milk Ordinance which was adopted in December, 1936, with grading and degrading provisions and has over 90 per cent compliance. St. Louis is unique among the larger cities in the country since it has no raw milk. A trip to one of the larger dairies is planned. Arrangements will also be made for those desiring to visit farms supplying milk.

THE UNIVERSITIES

St. Louis has two class A universities, namely, St. Louis University and Washington University. In both of these institutions visitors can obtain helpful information, for instance, Washington University has a Museum with a wonderful collection of rare specimens of bone pathology. St. Louis University is especially noted for the discovery of Theelin and vitamin K.

THE HOSPITALS

The City Hospital was founded in 1853 and now has a capacity of 1,104. It is estimated that from 90 to 95 per cent of the city's emergency cases are taken to the City Hospital. Recently new buildings were added, and the Bliss Hospital for the observation and treatment of psychiatric cases is one of the finest in the country. The new x-ray department and the City Hospital laboratories are worth seeing.

The Robert Koch Hospital is the city's institution for the treatment of tuberculosis. This institution was built primarily for the treatment of yellow fever, and later smallpox and leprosy cases were housed there. In 1910 it was converted into a tuberculosis sanatorium, and since 1922 new buildings were erected so that at the present time it is one of the most modern institutions in the country. It is one of the few tuberculosis institutions in the country that has no wards. It has a capacity of 688. Those interested in the construction of sanatoria or in tuberculosis generally cannot afford to miss the opportunity of visiting this institution.

The City Sanitarium and the St. Louis Training School are municipal institutions for the treatment of the insane and the feebleminded children respectively.

Homer G. Phillips Hospital is the municipal hospital for Negroes. It has a capacity of 685 beds. It was constructed in recent years and is one of the largest Negro hospitals in the country. It is administered by an all Negro staff. The consulting medical staff is made up of white physicians from both universities, alternating their services.

PRIVATE HOSPITALS

The private hospitals worthy of visiting are the Barnes Hospital, Children's Hospital, and others affiliated with the Washington University Med-

ical School. The St. Louis University group of hospitals, comprising St. Mary's Hospital, Mt. St. Rose for the treatment of tuberculosis, and the Desloge Hospital which is the main teaching hospital of St. Louis University are also well worth visiting.

Those interested in the treatment of crippled children will find that the Shriner's Hospital for Crippled Children is worth going to.

The Barnard Skin and Cancer Hospital will attempt to answer questions relating to the treatment and to the research phases of cancer, since considerable research work is constantly going on in this institution.

OTHER PLACES OF INTEREST

School physicians and others may find it profitable to visit the Central Institute for the Deaf which is one of the finest schools of this kind in the country.

Of interest to many public health workers, and especially to those interested in public health education, will be a visit to the Library of Education, which is a part of the St. Louis public school system. This library consists of sound and colored movies on educational subjects. This library is situated at 4466 Olive Street, and arrangements for visits will be made on request.

Engineers and laboratory workers may find it profitable to visit the Anheuser-Busch Brewery which is the world's largest brewery. The officers of the brewery cordially invite the members of the American Public Health Association to visit the plant at Broadway and Pestalozzi. Since the plant consists of 110 buildings covering 70 city blocks, the regular visitor's guided tour can cover only a few of the major points of interest.

Although beer is the main product of Anheuser-Busch, Inc., many other products of vital importance in the war are also produced. A few of these are—

starches, dextrins, corn syrups, malt syrups, table syrups, pharmaceutical yeast and yeast products or derivatives, cattle feeds, and baker's yeast. Special trips through the laboratories may be arranged for a limited number of interested individuals and the regular tour will be open to all.

ATTRACTIONS IN THE ST. LOUIS HEALTH DIVISION

The St. Louis Health Division, which is just across the street from the Convention Hall in the Municipal Courts Building, provides many points of interest and the delegates are cordially invited to visit all sections of the Division.

The Venereal Disease Clinic—situated in the Municipal Courts Building. Those interested in the control of venereal diseases will find it profitable to pay a visit to the Venereal Disease Clinic and see how the new *Venereal Disease Ordinance*, which is probably the only one of its kind in the country, is operated. It is purely a diagnostic clinic. The treatments are given by six coöperating hospitals and clinics to whom the patients are referred and for whom the Health Division pays 50 cents per treatment.

The St. Louis Health Division Bacteriological and Chemical Laboratories are well worth visiting. It is one of the public health laboratories applying gonorrhea culture methods routinely and one of the few that has a virus laboratory. It is one of two municipal public health laboratories that exercise constant check and control over the local private laboratories in the diagnosis of venereal diseases.

A visit to the Health Division Dental Extraction Clinic in the Municipal Courts Building may be of interest to the visiting dentists. In this clinic each child receives a medical examination of the heart and lungs before anesthesia is administered.

The Pasteur Clinic is of interest. Here methods of handling and treating those bitten by suspected rabid dogs will be seen.

Visits to the Health Division Immunization Clinic which operates 8 hours daily, the St. Louis Municipal Public Health Nursing, and to the Industrial Hygiene Section will prove profitable.

Health Centers: St. Louis has ten Health Centers located in the poorer sections of the city. In each Health Center the preventive work is carried out in maternal hygiene, child hygiene, tuberculosis control, and dental hygiene. Nurses will be particularly interested in the family folder system which has recently been instituted in these Health Centers.

A visit to the Out-Patient Pneumothorax Clinic may be of interest to those in the control of tuberculosis.

OTHER POINTS OF INTEREST

There are many other things worth seeing in and around St. Louis by the visiting members of the American Public Health Association, such as the St. Louis Medical Society's Library, which contains an exhibit of unusual medical historical documents; also, of interest is a visit to the grave of Dr. William Beaumont who contributed so much to gastric physiology, and who is buried in Bellefontaine Cemetery.

Trips to other places which some of the delegates might wish to visit will be arranged by the Local Committee upon request. A list of such places is given here:

1. Bellefontaine Farm, which is the home for delinquent boys
2. Ridge Farm County Department for convalescent children
3. Marine Hospital
4. United States Veterans Hospital
5. St. Louis Isolation Hospital
6. Division of Hygiene Board of Education
7. St. Louis Tuberculosis Society, especially the Residential Night and Day Camp
8. Missouri School for the Blind
9. Psychiatric Clinic

10. School of Public Health Nursing, St. Louis University
11. Junior League Occupational Work Shop

It should be remembered, especially by those interested in industrial hygiene, that our larger plants are not open for inspection on account of the war.

In conclusion, it should be stated that every employee of the St. Louis Health Division will do everything possible to carry out the wishes of the delegates regarding trips to any place in and around St. Louis, if transportation facilities permit.

OFFICERS AND EXECUTIVE COMMITTEE ST. LOUIS ANNUAL MEETING

Dr. Joseph F. Bredeck, Chairman of the Local Committee, for the Seventy-first Annual Meeting of the Association in St. Louis, Mo., October 27-30, announces the following Committee appointments:

Finance Committee

B. M. Lide, Jr., *Chairman*

Reception Committee

J. J. Bronfenbrenner, Ph.D., *Chairman*

E. G. McGavran, M.D., *Vice-Chairman*

Meeting Rooms

Percy M. Gash, *Chairman*

Melvin Tess, M.D., *Vice-Chairman*

Registration

F. H. Rein, *Chairman*

Dr. J. Earl Smith, *Vice-Chairman*

Scientific Trips

J. C. Willett, D.V.M., *Chairman*

Mildred Sanderson, *Vice-Chairman*

Entertainment Committee

Stephen Wolff, *Chairman*

Mrs. Virgil Loeb, *Vice-Chairman*

Ladies' Entertainment and Transportation

Mrs. Martin J. Glaser, *Chairman*

Mrs. Joseph C. Peden, *Vice-Chairman*

Attendance

Robert C. Farrier, M.D., *Chairman*

John Buxell, *Vice-Chairman*

Publicity

H. I. Spector, M.D., *Chairman*

Mrs. Schuyler M. Smith, *Vice-Chairman*

A.P.H.A. SUSTAINING MEMBERS, 1942

IT is now twenty-five years since Sustaining Members have been a part of the membership in this professional society. Their contributions this year, when measured in dollars, amount to 12 per cent of the income from dues. When measured in significance, however, they mean an even more substantial share in Association activity, for without such help it would be impossible to publish such reference works as the Standard Methods series in Water, in Dairy Products, in Diagnostic Procedures and Reagents, or such reports as that on the Control of Communicable Diseases, a report which in circulation perhaps exceeds any other regularly used by the professions.

In expressing again the appreciation which the Association feels toward these fourteen members, the Executive Secretary has said to them that the past year turned out to be an even more dynamic year for the public health profession than we had guessed. The need for an excellent quality of professional health work moved into the center of public attention, and the demands for people and Association services exceeded all previous records.

The reports from Honolulu and Alaska now tell us how the health departments and their related agencies moved in to protect both civil and military populations in the emergency. From the other side of the water comes

the testimony of the Right Honorable Malcolm Macdonald, formerly British Minister of Health, who emphasized before the Tolan Committee of Congress the critical importance of health services in building morale. The need for this professional society of public health workers was never more apparent.

*Sustaining Members of the A.P.H.A., 1942
Life Insurance Group*

*Year
Elected*

The Equitable Life Assurance Society New York, N. Y.	1918
The John Hancock Mutual Life Insurance Company Boston, Mass.	1924

The Metropolitan Life Insurance Company New York, N. Y.	1918
The National Life Insurance Company Montpelier, Vt.	1918

The Prudential Insurance Company of America Newark, N. J.	1917
The Sun Life Insurance Company of America Baltimore, Md.	1925
The Traveler's Insurance Company Hartford, Conn.	1933
The Union Central Life Insurance Company Cincinnati, Ohio	1918
The Western & Southern Life Insurance Company Cincinnati, Ohio	1919

Other Individuals and Organizations

*Year
Elected*

The Chlorine Institute, Inc. New York, N. Y.	1928
Mrs. Moses H. Cone Baltimore, Md.	1920
The Gilliland Laboratories, Inc. Marietta, Pa.	1924
The International Association of Ice Cream Manufacturers Washington, D. C.	1928

NOMINATIONS FOR THE GOVERNING COUNCIL

IN accordance with the By-Laws of the Association, the Nominating Committee for Governing Council members, consisting of one Fellow from each Section, reports the following nominations for the Governing Council. The By-Laws provide that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, provided such petition is received fifteen days before the Annual Meeting." The Chairman of the Committee is Friend Lee Mickle, Sc.D., Director of Laboratories, State Department of Health, Hartford, Conn. The other members are: Herman G. Baity, Sc.D., Engineering Section; J. V. DePorte, Ph.D., Vital Statistics Section; Albert S. Gray, M.D., Industrial

Hygiene Section; Ruth E. Grout, Ph.D., Public Health Education Section; Wilton L. Halverson, M.D., Health Officers Section; Albert C. Hunter, Ph.D., Food and Nutrition Section; Kenneth F. Maxcy, M.D., Epidemiology Section; Marian G. Randall, R.N., Public Health Nursing Section; William D. Stovall, M.D., Laboratory Section; Estella F. Warner, M.D., Maternal and Child Health Section.

There are thirty elective councillors on the Governing Council of whom ten are elected each year. The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting in St. Louis will be elected for the three year term 1942-1945.

Gaylord W. Anderson, M.D.
University of Minnesota
Minneapolis, Minn.

Margaret G. Arnstein, R.N.

WANTED: The following issues of the *American Journal of Public Health*—July and August, 1941; and January, 1942. The Association will be glad to pay postage.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Ray H. Ballard, M.D., 817 South 11th St., Laramie, Wyo., Director, Student Health Service, Univ. of Wyoming
 Lt. Commdr. Arthur P. Black, M.C., U.S. N.R., U. S. Naval Air Station, Kingsville, Tex., Sanitation Officer
 Albert L. Chapman, M.D., 255 Linden St., Moorestown, N. J., Dist. Health Officer
 Hubert Flurry, M.D., 1724-24th Ave., Meridian, Miss., Trainee, Lauderdale County Health Dept.
 William P. Frank, M.D., 2216 Winthrop Drive, Alhambra, Calif., Communicable Disease Physician, Los Angeles County Health Dept.
 Phillip J. Holabach, M.D., Whitman County Health Dept., Colfax, Wash., Health Officer
 Raymond F. Kaiser, M.D., M.P.H., 786 30th Ave., San Francisco, Calif., Passed Asst. Surgeon, U. S. Public Health Service
 Maurice Kamp, M.D., 217 E. Spring St., New Albany, Ind., P. A. Surgeon (R), U. S. Public Health Service
 Romeo H. Lewis, M.D., M.P.H., 33 Warwick St., Boston, Mass., Student, Harvard School of Public Health
 Paul A. Lindquist, M.D., M.S.P.H., 218 E. First St., Monroe, Mich., Director, Monroe County Health Dept.
 Murphy P. Martin, M.D., P. O. Box 128, Thibodaux, La., Director, Lafourche Parish Health Unit
 Abraham Oppenheim, M.D., Arcadia, La., Director, Bienville Parish Health Unit
 John E. Petcoff, M.D., 2520 Monroe St., Plaza Apt., Toledo, Ohio, Acting Director, Public School Health Service, Board of Education
 Wallace W. Schwabland, M.D., 317 County-City Bldg., Seattle, Wash., King County Health Officer
 Kenneth C. Sheriff, M.D., Monterey County Hospital, Salinas, Calif., Monterey County Health Officer
 Frank Ternocky, M.D., Bloomville, Ohio, Health Commissioner, Seneca County Dist.
 Thomas McK. Thompson, M.D., M.P.H., 120 Front St., Philipsburg, Pa., Dist. Medical Officer, State Dept. of Health

Laboratory Section

Edward S. Biddle, M.S., 29 E. Park Place, Newark, Del., Research Bacteriologist, Univ. of Delaware
 William Burrows, Ph.D., Dept. of Bact., Univ.

of Chicago, Chicago, Ill., Asst. Professor of Bacteriology

Carl A. Frey, Ph.D., 54 Shannon Ave., Athens, Ohio, Professor of Bacteriology, Ohio Univ.
 Stanley J. Gilmore, 634 N.E. 60th Ave., Portland, Ore., City Bacteriologist, Bureau of Health

John W. Williams, M.D., 10-424 Massachusetts Institute of Technology, Cambridge, Mass., Associate Professor of Public Health Laboratory Methods

Vital Statistics Section

Huldah H. Ainsworth, Waterbury Hospital, Waterbury, Conn., Medical Records Librarian

Alberto E. Calvo-Sucre, M.P.H., P. O. Box 1158, Panama City, Republic of Panama, Chief, Division of Vital Statistics and Epidemiology

Engineering Section

Anthony L. Bavone, Box 1268, Minot, N. D., Sanitary Engineer, Minot-Ward Health Unit
 Harold A. Kemp, 1721 N. Huntington St., Arlington, Va., Head Engineer, Office, Chief of Engineers, U. S. Army

Z. H. Legg, Fayetteville, W. Va., Sanitarian, Fayette County Health Dept.

Robert J. Ollry, M.S.P.H., 348 Beacon St., Boston, Mass., Instructor in Biology, St. Lawrence Univ., Canton, N. Y.

William Samborski, M.S.P.H., 3919 John R. St., Detroit, Mich., Senior Sanitary Engineering Aid, City Dept. of Health

Industrial Hygiene Section

Charles D. Bitting, 39 Hillside Ave., Kenil, N. J., Safety Supervisor, Hercules Powder Co.

Food and Nutrition Section

Fred C. Baselt, 230 Park Ave., New York, N. Y., Manager of Research, Atlantic Division, American Can Co.

Philip R. Carter, D.V.M., 3736-47th Ave., South, Minneapolis, Minn., Veterinary Officer, Veterinary Corps, U. S. Army

Robena C. Carter, 700 South Beacon, Sedalia, Mo., Unit Supervisor, Housekeeping Aide Project, WPA

Maternal and Child Health Section

Powell C. Carrel, D.D.S., M.P.H., 123 Argyle Ave., West Hartford, Conn., Chief, Div. of Dental Hygiene, State Dept. of Health

William W. Kelton, Jr., M.D., 707 W. 7th St.,

Austin, Tex., Director, Maternal & Child Health, Austin-Travis-Bastrop Health Unit
 Elsie F. Norman, 311 Brush Creek, Kansas City, Mo., Dist. Supervisor, Child Protection Program, Works Projects Admin.
 E. Bliss Pugsley, M.D., 245 Cooper St., Council House, Ottawa, Canada, Executive Asst., Div. of Maternal & Child Hygiene, The Canadian Welfare Council
 Elihu L. Schuman, D.D.S., 171 Eastern Parkway, Brooklyn, N. Y., Dental Officer, U. S. Veterans' Admin.
 Jess B. Spielholz, M.D., 506 Ft. Washington Ave., New York, N. Y., Clinic Pediatrician, New York City Dept. of Health

Public Health Education

Herbert Bauer, M.D., General Hospital, San Luis Obispo, Calif., San Luis Obispo County Physician
 Jane L. Lyman, 228 Edwards St., New Haven, Conn., Student, Yale Univ. School of Public Health
 Phyllis K. McCalmont, M.A., 519 Smithfield St., Pittsburgh, Pa., Executive Secretary, Child Health Div., General Health Council of Allegheny County
 Roy L. Reinarz, 5010 Duval St., Austin, Tex., Sanitary Reserve, State Dept. of Health
 Claire E. B. Reinhardt, M.Ed., C.P.H., 1551 Franklin Ave., Mineola, L. I., N. Y., Director of Education, Nassau County Cancer Committee
 Kyle C. Rigsby, 100 N. 6th Ave., East, Cullman, Ala., Asst. in Health Education, Div. of Statistics and Reports, U. S. Public Health Service

Public Health Nursing Section

Margaret D. Arbuckle, Grantsville, W. Va., Public Health Nurse, State Health Dept.
 H. Eleanor Johnson, Box 216, Williamsburg, Va., Chief Nurse, Peninsula Health Dist.
 Ada Kruger, R.N., Lincoln County Health Dept., Hamlin, W. Va., Public Health Nurse
 Freda M. LaKamp, Farm Bureau Bldg., Waterloo, Ill., County Nurse, Monroe County Nursing Service
 Leah E. Miller, Health Dept., Lumberton, N. C., Public Health Nurse, U. S. Public Health Service
 Emily G. Murray, R.N., P. O. Box 1118, Lufkin, Tex., Nurse, Angelina County Child Welfare Board
 Ethel C. Ryckman, R.N., 39 North St., Hillsdale, Mich., Senior Counsellor, Hillsdale County Health Dept.
 Elizabeth J. Smith, 351 Eighth Ave., N., Twin Falls, Ida., School Nurse, South Central Dist. Health Unit

Epidemiology Section

Harry H. Henderson, M.D., State Health Dept., Richmond, Va., State Epidemiologist
 Ira D. Hirschy, M.D., 524 Linden St., Ann Arbor, Mich., Student, Univ. of Michigan, School of Public Health
 Edward Kupka, M.D., 703 California State Bldg., Los Angeles, Calif., Chief, Bureau of Tuberculosis, State Dept. of Public Health
 Joseph Py, D.O., 460 Lyceum Ave., Philadelphia, Pa., Head, Dept. of Preventive Medicine and Bacteriology, Philadelphia College of Osteopathy

Unaffiliated

Jean G. Ferguson, 428 Yale Ave., New Haven, Conn., Student and Asst. in Public Health Dept., Yale Univ.
 Emil A. Tiboni, Greyledge Farm, R.F.D. 1, Glastonbury, Conn., Sanitary Inspector, Dept. of Health, East Hartford, Conn.

DECEASED MEMBERS

John N. Eisman, M.D., Cincinnati, Ohio, Elected Member 1941, Epidemiology Section
 Howard W. Hassell, M.D., Bridgeport, Pa., Elected Member 1939, Health Officers Section
 Harold H. Keller, Philadelphia, Pa., Elected Member 1932, Industrial Hygiene Section
 J. P. Russell, M.D., Berkeley, Calif., Elected Member 1938, Elected Fellow 1940, Industrial Hygiene Section
 A. N. Talbot, Urbana, Ill., Elected Member 1913, Charter Fellow 1922, Engineering Section
 James D. Trask, M.D., New Haven, Conn., Elected Member 1936, Epidemiology Section
 William H. Best, M.D., Brooklyn, N. Y., Elected Member 1936, Elected Fellow 1939, Health Officers Section
 L. T. Clark, D.Sc., Detroit, Mich., Elected Member 1919, Elected Fellow 1931, Laboratory Section
 Walter S. Goodale, M.D., Buffalo, N. Y., Elected Member 1923, Epidemiology Section
 Abraham Lichterman, Ph.D., Brooklyn, N. Y., Elected Member 1935, Elected Fellow 1938, Food and Nutrition Section
 Max P. Schranck, M.D., Twin Falls, Ida., Elected Member 1940, Industrial Hygiene Section
 Winfield Carey Sweet, M.D., Dr.P.H., Lashie, Burma, India, Elected Member 1924, Epidemiology Section

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

U. S. CIVIL SERVICE COMMISSION

The Commission has announced unassembled examinations for Junior Public Health Nurse at \$1,800 a year and Junior Graduate Nurses at \$1,620 a year, under which the training and age requirements of announcements No. 88 and 103 of 1941 have been amended. Persons interested should communicate with the U. S. Civil Service Commission in Washington or obtain the amended announcements at any first or second class post office.

The Commission has announced again its need for public health nursing consultants in war work. The new announcement now provides for 5 grades and for appointments in the Children's Bureau, Department of Labor, U. S. Public Health Service, and Federal Security Agency. Salaries range from \$2,600 to 5,600 a year. No age limits have been set. Positions exist both in the United States and foreign countries. War service appointments will be made to extend generally for the duration of the war and no longer than 6 months afterward. Duties are to carry out, in accordance with the rank of the position, nursing or nursing education programs; and to act in advisory capacity to Federal agencies, or to State, County, and municipal organizations.

There will be no written test, qualifications being judged solely from review of experience, education, and training of applicants. Persons applying must have completed a 4 year course in a recognized college and 1 year's special program of study in public health nursing approved by the National Organization for Public Health Nursing; must also have graduated from an accredited school of nursing affiliated with a hospital having a daily average of 100 or more bed patients; be registered nurses in a state or territory of the United States or the District of Columbia, and have had appropriate general public health nursing supervisory experience. Additional credit given for completion of approved college course in statistical analysis, public health nursing, supervision, social hygiene, tuberculosis control and maternity, pediatric or orthopedic nursing; also for certain appropriate experience as instructor, consultant, or investigator.

For positions in Children's Bureau additional progressive experience in specialized fields of maternal or child health is required for the top grade and may be substituted for part of the general experience prescribed for the other grades.

Applications must be filed with the U. S. Civil Service Commission, Washington, D. C., and will be accepted until the needs of the service have been met. Forms may be obtained direct from the Commission or at any first or second class post office.

PHYSICIANS NEEDED IN CANAL ZONE

The U. S. Civil Service Commission announces an examination to secure physicians for clinical service in the Panama Canal Zone. Graduation from a class A medical school subsequent to May 1, 1920, is required, and the applicant must be under 50. 25 to 35 years of age preferred. Entrance salary \$4,000. Persons interested should communicate with the U. S. Civil Service Commission, Washington.

MERIT SYSTEM COUNCIL, OREGON STATE BOARD OF HEALTH AND CRIPPLED CHILDREN'S DIVISION, UNIVERSITY OF OREGON MEDICAL SCHOOL

have announced merit examinations in practically all professional public health fields, including Health Officers, Nurses, Sanitary Engineers, Laboratory Workers, Vital Statisticians, Consultants in the fields of Health Education, Hearing and Vision, Nutrition, Oral Health and Physiotherapy. Two clerical positions, Fiscal worker and Administrative Clerk are included in this list as is also the position of Merit System Personnel Technician.

Interested persons may get full particulars regarding the positions and examinations by writing H. J. Scars, Merit System Supervisor, P. O. Box 88, Portland, Ore.

The Indiana State Personnel Division, 141 South Meridian Street, Indianapolis, announces that applications may be filed at any time until further notice for the following positions:

Orthopedic Nursing Consultant I (women only).....	\$150-200 mo.
Physician I (General)	165-250 mo.
Physician II (General)	250-325 mo.
Physician II (Tuberculosis)	250-325 mo.
Physician I (Psychiatric)	185-265 mo.
Physician II (Psychiatric)	250-325 mo.
Local Public Health Director	300-360 mo.

POSITIONS AVAILABLE

Physician with either public health training or experience in local health department administration to serve as health director in a county health department in mid-western state. Salary \$4,000 and \$500 travel (flat rate). Well established department with offices in attractive little city of 10,000. Write Box T, Employment Service, A.P.H.A.

Wanted: Trained Public Health Nurse, starting salary \$1,500 per year and traveling expense, increase to \$1,620 within 6 months. Saginaw County Health Dept., Saginaw, Mich.

Western state department of health will consider applications from physicians to fill four existing vacancies among county health officers, one vacancy in venereal disease control and positions as laboratory technicians. Write Box S, Employment Service, A.P.H.A.

County Public Health Nurses for New Mexico. Must have four months' post-graduate instruction under one of the recognized public health nursing courses and one year's experience. Must drive and have a car. Address inquiry to State Health Department, Santa Fe, N. M.

PUBLIC HEALTH ENGINEER

Responsible professional public health engineering involving field investigations and office studies in the application of sanitary measures. The more difficult engineering and sanitation field surveys include supervision over public water supplies, sewerage systems and sewage treatment plants and review of plans for same, and promotion and supervision of sanitation programs. Minimum qualifications: Training and experience equivalent to 3 years' civil engineering experience, including 2 years in public health or sanitary engineering; or completion of an academic year of graduate study and a year's experience in sanitary or public health engineering; and graduation from a college of recognized standing with a major course in civil or sanitary engineering. The salary range is \$205 to \$250 per month depending upon experience. Apply Box E, Employment Service, A.P.H.A.

Southwestern state health department seeks 2 physicians for assignment to district health units, personally to conduct several small venereal disease clinics on a rotating schedule. Experience preferred but not required. Salary \$3,000, plus actual travel allowance not to exceed \$1,200. Write Box V, Employment Service, A.P.H.A.

The New Mexico State Department of Public Health will consider applications for the position of Assistant Director of the Maternal and Child Health Division. Address inquiries to the State Department of Public Health, Santa Fe, N. M.

Wanted: Trained Public Health Nurse, starting salary \$1,500 per year and traveling expenses. Increase may be expected within 6 months. Shiawassee County Health Department, Corunna, Mich.

Sanitarian Wanted: Starting salary \$1,800 per year with travel allowance of \$50 per month. Man must have his own car. Bachelor's degree followed by at least one year's course or its equivalent in subjects necessary for one entering the public health field, or an engineering degree plus one year's experience in sanitary or public health engineering required. A course in public health training may be considered as an equivalent for a part of the experience requirement. Apply Director District Department of Health No. 6, Central Office, Newberry, Mich.

Wanted: Nurse for county health work. Salary \$1,800 per year with travel allowance (additional) of \$500 per year. Address District Health Department 2, West Branch, Mich.

Instructor in Bacteriology, Medical School, large midwestern university, M.D. (or Ph.D. or D.Sc. in Bacteriology); Male. Salary \$1,800 to \$2,500 according to age and experience. Write Box D, Employment Service, A.P.H.A.

Bacteriologist with Ph.D. or equivalent and teaching experience wanted in western state university. Must be immune to military service call. Salary about \$2,500. Write Box A, Employment Service, A.P.H.A.

Laboratory technician wanted. Salary \$1,500. Apply Dr. R. G. Beachley, Direc-

tor of Health and Welfare, Arlington County Health Department, Arlington, Va.

POSITIONS WANTED

ADMINISTRATIVE

Teaching or administrative position desired by physician, aged 48. Experienced teacher in preventive medicine and public health, now employed at prominent medical school; 20 years' experience in municipal health administration and epidemiology. A-491

Physician, B.S., M.D., and M.S.P.H., University of Michigan, aged 35, experienced city-county health administration and as director university student health service. Will consider permanent responsible position offering good income. A-492

Physician with 25 years full-time experience in public health administration is available for immediate appointment. Moderately hard of hearing; otherwise fully able. Salary \$4,500 or better. A-497

Physician, M.D., C.P.H., aged 47, seeks position in administrative work. Experienced in venereal disease control and industrial medicine. A-485

Physician, aged 47, M.D. Creighton University, M.S.P.H. Michigan, experienced in school health and as director of county health unit, seeks position as administrator in state or local health department. A-498

Physician, aged 37, M.D., McGill, D.P.H., Toronto, experienced as health officer and director of public health training, seeks position in administrative work. A-499

WOMEN PHYSICIANS TRAINED IN PUBLIC HEALTH

Woman aged 34, M.D., University of Basle, Switzerland, M.S.P.H. DeLamar Institute, Columbia University. U. S. citizen. Excellent references. Especially interested in industrial hygiene. A-493

Woman aged 41, M.D. Columbia University, M.S.P.H. DeLamar Institute, experienced in epidemiology and research, seeks position offering administrative experience. A-494

Woman physician, aged 48, M.D., University of Vienna. Excellent European pediatric experience. Seeks position in pediatrics, administration or statistical research. A-495

Woman physician, M.D., Rush, M.P.H., Michigan, 13 years' experience in school medical service and administrative county health unit, seeks administrative position. New York area preferred. A-500

HEALTH EDUCATION

Health Educator, Negro, man with background of High School administration and M.S.P.H. from University of Michigan, seeks position in Health Education. Public agency or educational field. Excellent references. H-497

Health Educator, M.A. in Education, 10 years' background in community organization for public health education, also teaching of personal and community health at high school and college levels. Public health nurse, able to teach mental and social hygiene as well as general health education. East preferred. H-498

Teacher and research worker, man, Ph.D., age 52. Extensive record as college professor of biology and hygiene and investigator, for the past two years engaged in research. H-499

Woman, Sc.D., Johns Hopkins, M.S., Chicago. Chief interests health education, nutrition, biochemistry, 14 years' teaching experience in college, 7 years head of departments. Excellent recommendations. H-505

Health Educator. Man with M.S. in preventive medicine and public health. Negro. Seeks position in Health Education or field work with official or non-official agency. H-500

Woman with master's degree in health education, 12 years' successful experience in public school and college teaching, administration and research. Will consider position in normal school, public schools, or in official or nonofficial health agencies. Prefers South or East. Available at once. H-501

LABORATORY

Milk Sanitarian and Technologist, age 37, Ph.D., Bacteriology, Wisconsin, 10 years' experience in milk and food sanitation from industrial and official angle, seeks administrative position with opportunity for research or investigational work preferred. L-381

Chemist, Sc.D., Biochemistry, Johns Hopkins University. Age 31. Public health laboratory experience, teaching experience. Desires position with promise of advancement, preferably in commercial organization. L-461

Bacteriologist, young man 28, with B.S. in industrial science, experienced in newspaper work, salesmanship and now employed in state department of health laboratory, seeks position as bacteriologist or doing promotional work of public health nature. L-465

MISCELLANEOUS

Veterinary Doctor, M.P.H., University of Pennsylvania, age 27, with two years

of practice, seeks position in food, meat, milk, or livestock sanitation with state or local health department. Also interested in teaching position with research facilities. M-451

Public Health Nurse with M.A. degree wishes position in health supervision and teaching in college or public school. West preferred. M-452

Administrative Assistant or Health Educator, woman, M.A. 10 years' experience in health agency offices; 7 years' teaching experience; writer on health and other subjects; experienced in independent research; some training in social work; some hospital experience. M-453

NEWS FROM THE FIELD

NEW YORK CITY CHANGES HEALTH COMMISSIONERS

MAYOR LAGUARDIA on July 16 announced the resignation, on account of ill health, of John L. Rice, M.D., who has been Commissioner of Health since January 1, 1934, and the appointment of Ernest L. Stebbins, M.D., M.P.H., Professor of Epidemiology at the DeLamar Institute of Public Health, Columbia University, New York, N. Y., as Commissioner, effective immediately. Dr. Rice will continue to serve the City as a special consultant.

Dr. Stebbins, who was born in Iowa in 1901, is a graduate of Dartmouth College, the Rush Medical College, Chicago, in 1929, and of Johns Hopkins University School of Hygiene and Public Health in 1932. He served as epidemiologist of the Virginia State Department of Health in 1931, and from 1932 to 1934 was Health Officer of Henrico County, Virginia. From 1934 to 1940 he was a staff member of the New York State Department of Health, serving as epidemiologist, district health officer, Director of the Division of Communicable Diseases, and Assistant Commissioner. Dr. Stebbins is Secretary of the Epidemiology Section of the American Public Health Association, and a member of the Governing Council.

A.P.H.A. SURVEY IN ILLINOIS

UNDER the auspices of the Committee on Administrative Practice of the American Public Health Association and its Subcommittee on State Health Administration, a survey of public health administration in Illinois has been under way for several months. Carl E. Buck, Dr.P.H., Field Director of the committee, has been in charge of the study with the assistance of a local staff.

A progress report entitled "Public Health Needs in Illinois" is summarized by the *Illinois Health Messenger* as recommending the creation of a state-wide public health committee which should endeavor to develop a widespread popular understanding of the importance of state and local health departments so that politics may not interfere with the appointment or retention of properly qualified public health personnel and the plans for developing services. The report recommends that a public health building be provided to house the state department of public health. It is further recommended that the state construct and maintain one or more state tuberculosis sanatoria in those areas not adequately served by existing hospital facilities, and that a county sanatorium of about 2,000 beds be constructed in Cook County for patients outside of Chicago.

The progress report recommends that the State Department of Public Health in Illinois be given specific authority to control the installation and operation of all public water systems and that the department be authorized to require proof of competency from all operators of public water purification plants, sewage treatment works, and pasteurizing plants. Other recommendations are made by this progress report.

The work of organizing the recommended non-partisan State-wide Public Health Committee is already under way. Several local lay committees for public health education which have been functioning for some time in various sections of the state have already offered coöperation and eventually it is expected that these local groups will elect to affiliate with the larger organization.

The primary responsibility of the

Illinois State-wide Public Health Committee will be "to disseminate accurate information for the purpose of developing a widespread, intelligent lay understanding of existent public health problems, what is being done, and what can be done to solve them." Serving as Chairman of the committee is Frederic C. Woodward, Vice-President Emeritus of the University of Chicago, a man long known as a public spirited leader in civic affairs, a distinguished educator, and a lawyer of national reputation. Mr. Woodward is dividing the state into ten or twelve districts, for each of which he will later appoint a district chairman to facilitate committee operations. Eventually there are to be affiliates or subdivisions of the state-wide organization in every county.

In order that these groups may effectively define public health problems and suggest ways and means of meeting them, they will consult the state and local public health authorities. For this purpose the Illinois Director of Public Health, Dr. Roland R. Cross, has made available to Mr. Woodward the services of the personnel of the State Division of Public Health Instruction, under the direction of Mrs. Leona East, Chief.

HEALTH GAINS IN GREAT BRITAIN

A SUMMARY of a statement made by the British Minister of Health, Mr. Ernest Brown, before the House of Commons, was carried by *The New York Times* on July 1. According to the Minister of Health, Britain's health after almost three years of war was in many ways better than it has been, even despite an increase in tuberculosis and spinal meningitis. He stated that diphtheria was still the greatest killing disease of children between the ages of 4 and 10, and that diphtheria had killed more children last year than did German bombs.

Scarlet fever and typhoid fever had

become scourges of the past, the former claiming only 133 victims in 1941, and the latter 143 out of fewer than 5,000 cases. He said that the lack of serious typhoid fever epidemics after bombings was one thing which proved surprising to United States visitors but that no deaths during heavy bombings were caused by water-borne infection.

Confirming statements made by Sir Wilson Jameson, Chief Medical Officer of the Ministry of Health, before the American Public Health Association at the 1941 Annual Meeting, Mr. Brown said that there had been a drop in admissions to insane asylums. These had stood at 30,000 in 1938 and 1939 but dropped to 28,000 in 1940 and to 26,000 in 1941. Tuberculosis, he said, was giving the most trouble, probably because of blackout crowding and the cessation of house building. The nursing situation was unsatisfactory, particularly in the case of tuberculosis.

MERIT SYSTEM CONSULTATIONS

PROVISIONS will be made at the 71st Annual Meeting of the American Public Health Association in St. Louis, October 27-30, for consultations between those concerned with the administration of merit system plans and the staff of the Association conducting the Merit System Study under the auspices of the Committee on Professional Education. Appointments for consultation on this subject with Dorothy Deming, R.N., may be made through the Association office in the Auditorium.

LESLIE DANA GOLD MEDAL

THE Leslie Dana Gold Medal, awarded annually for outstanding achievements in the prevention of blindness and the conservation of vision, will be presented this year to Lewis H. Carris, Director Emeritus of the National Society for the Prevention of Blindness.

PENNSYLVANIA PUBLIC HEALTH ASSOCIATION

THE Pennsylvania Public Health Association, under the Presidency of Lieutenant Colonel A. Parker Hitchens, M.C., met in Pittsburg on May 15 jointly with the Pennsylvania Association of Dairy Sanitarians and the Tri-State Food and Health Association. A resolution passed by the Pennsylvania Public Health Association (in abridged form) follows:

WHEREAS: The Pennsylvania Public Health Association, recognizing the importance to the public health and the public welfare of the dairy industries, at this particular period in our National History; and recognizing the fact that the dairy farmers, the processors and the distributors, and especially the consumers of dairy products, owe their greatest debt to sanitary science; and recognizing the commencement of the era of the scientific study and handling of milk and other dairy products in the bacteriological work initiated by Professor William T. Sedgwick, of Boston, Mass., and

WHEREAS: A painstaking review of the accomplishments of this Half Century of Milk Sanitation has revealed overwhelming evidence in support of the fact that no milk, however carefully each stage in its production is supervised, can be considered safe for human consumption unless it is collected in a cleanly manner, cooled quickly, pasteurized properly, adequately protected after pasteurization, and kept cold until its final utilization or preparation for use in the dietary, and

WHEREAS: the present needs of our country are causing everyone to explore the possibilities of curtailing the expenditure of time and materials to the limit of practicability and expediency, the public welfare demands that no procedure be authorized which may tend to reduce the consumption of wholesome, pasteurized milk; therefore be it

RESOLVED: that the Pennsylvania Public Health Association convened in this joint celebration* of a Half Century of Milk Sanitation heartily acknowledges its debt to the pioneer work of William T. Sedgwick, to other scientists, and to all the various workers in agriculture and in industry who have contributed to our recognition of the value of milk in human nutrition and to the development of methods by which safe milk can be produced eco-

nomically and made universally available; and be it further

RESOLVED: that in recognition of the dangers of infection to which milk is constantly exposed, it is the considered opinion of these associations that only milk that has been properly pasteurized or boiled should ever be used for human nutrition; and, be it further . . .

RESOLVED: that any measure which may tend to curtail the availability of fresh and pasteurized milk is firmly opposed and the opinion is recorded that responsible officials should use every effort to prevent the adoption of any such measure or practice; and be it further

RESOLVED: that in promulgating these resolutions this Association is acting in accordance with its conviction that raw milk is always a potential carrier of dangerous infection and that now there is more reason than at any other period in our Nation's history to do everything possible to control preventable disease, and be it further

RESOLVED: that it is our considered opinion that *not to control disease is sabotage.*

HEALTH EDUCATION IN MALARIA CONTROL

THE U. S. Public Health Service has recently initiated an interesting experiment in health education as a part of its program for malaria control in war areas. A local teacher has been employed for the summer in each of 25 counties in 7 southern states to organize the communities in and around war areas for health education in malaria control. The teachers were assembled in Memphis, Tenn., June 16-26, and given an intensive course on the essential facts of malaria control and methods of community organization for health education. After completing the orientation course, the teachers returned to their own counties and were assigned to the local health department as health educators. They will give particular attention to educating their communities in malaria control measures.

It is anticipated that the teachers will continue health education as a part of their regular activities in their respective schools during the coming year.

ASSOCIATION OF FOOD AND DRUG OFFICIALS OF THE UNITED STATES

THE 46th annual conference of the Association of Food and Drug Officials of the United States was held at the Pennsylvania Hotel, New York, N. Y., June 1-5. The newly elected officials are as follows:

President—Sarah V. Dugan, Director, Bureau of Foods, Drugs and Hotels, State Department of Health, Louisville, Ky.

Vice-President—H. C. Lythgoe, Director, Division of Foods and Drugs, State Department of Health, Boston, Mass.

Secretary-Treasurer—J. C. Schneider, Chief, Bureau of Food and Drugs, State Board of Health, Indianapolis, Ind.

Executive Committee—W. A. Queen, U. S. Food and Drug Administration, Washington, D. C.; George Marsh, Director, Division of Agricultural Chemistry, State Department of Agriculture and Industries, Montgomery, Ala.; Jacob W. Forbes, Head, Food and Drug Section, State Department of Health, New Orleans, La.; William F. Reindollar (Chairman of the Editorial Committee), Chief, Bureau of Chemistry, State Department of Health, Baltimore, Md.

INDUSTRIAL HYGIENE AND MEDICAL SERVICE IN THE WAR INDUSTRIES

IT has been announced by James G. Townsend, M.D., Chief of the Division of Industrial Hygiene, National Institute of Health, Bethesda, Md., that, on the request of the Committee on Industrial Medicine of the National Research Council, a manual is being prepared on the above subject intended for wide distribution among the medical profession. The general editor will be William M. Gafafer, Sc.D., Chief of the Statistical Unit of the Division of Industrial Hygiene, National Institute of Health.

The Committee on Industrial Medicine of the Division of Medical Sciences, National Research Council, has pointed out that the change-over of industry to the manufacture of war materials is resulting in modifications of occupational health hazards, the introduction of new occupational disease exposures

and certain variations in the industrial medical procedures. The following are illustrative:

1. There is increased usage of cutting oils, compounds, and chemicals, many of which are capable of causing the industrial dermatoses.
2. Grinding operations have multiplied and these entail exposures to aluminum oxide, silicon carbide, and other grinding materials. While the dusts from grinding operations have not been regarded as harmful to health, disabilities occurring in workers so exposed are coming to be regarded as compensable.
3. Shot blast operations are being replaced by sand blasting, and new installations of this nature are consistently using sand.
4. In an effort to speed up pickling operations, there is a tendency to increase the concentrations of acids in the pickling tanks, with consequently more contamination of the air with fine droplets of the acids.
5. Solvents are being more widely used and certain of the newer ones are purported to be non-toxic. Inasmuch as most of them are in the chlorinated hydrocarbon group of chemicals, they can be assumed to be more or less toxic.
6. Paint spraying operations are being modified, requiring radical readjustments in ventilation procedures.
7. There is a tendency toward longer working hours and, consequently, longer hours of exposure to harmful materials and shorter periods of recuperation.
8. It is becoming more and more necessary to employ women, older men, and young men who are not eligible for military service, many of whom require selective placement, which is a function of the plant medical service.
9. It is necessary that the medical service in the war industries be integrated with the emergency medical service of civilian defense. Details necessary to this objective are not understood by the industrial physicians as yet.

PHYSICAL THERAPY COURSE AT COLUMBIA UNIVERSITY

COLUMBIA University announces that beginning September, 1942, a program of professional studies for the training of Physical Therapy technicians will be offered. This training and instruction will extend over a two year period, and has been organized in compliance with the requirements set

down for such programs by the Council of Medical Education and Hospitals of the American Medical Association. The course is being set up in University Extension in close relationship with the College of Physicians and Surgeons of Columbia University, and the Nursing, Education and Health, and Physical Education Departments of Teachers College. The clinical and laboratory instruction will be given at the Vanderbilt Clinic, Neurological Institute, Presbyterian Hospital, and New York Orthopedic Dispensary and Hospital.

Two years or 60 semester hours of college, including courses in Physics and Biology, shall be required, or graduation from an accredited School of Nursing or an accredited School of Physical Education.

A Certificate of Proficiency in Physical Therapy will be granted by Columbia University to those completing the course. Further information may be obtained by writing the Office of the Committee on Physical Therapy, Room 303 B, School of Business, Columbia University, New York, N. Y.

SURVEY OF CONNECTICUT HOUSING

THE Committee on the Hygiene of Housing of the American Public Health Association has published the results of test surveys of housing conditions in slum and low-rent areas, conducted in three Connecticut cities. These studies were made with the appraisal technic developed by the committee as a guide to housing inspection and enforcement by local health departments.

The committee's report, published in the February 27 and April 3, 1942, issues of *Public Health Reports*, shows that the method used for rating the quality of housing provides a clear discrimination between adequate and substandard dwellings, and also that it furnishes specific guidance for remedial

measures by enforcement agencies. Reprints of the report are available on request from the Committee on the Hygiene of Housing, 310 Cedar Street, New Haven, Conn.

This appraisal technic has been officially adopted for a demonstration survey in a large district of slums and blighted areas of New Haven, Conn., which is now being conducted under the joint sponsorship of the local health department, housing authority, and city plan commission, the Connecticut Department of Health, and the Committee on the Hygiene of Housing. It is the purpose of the coöperating agencies to develop a comprehensive and integrated official program of housing enforcement, rehabilitation and reconstruction for the problem areas covered by the survey, and to stimulate the extension of such coöperative studies to other portions of New Haven and to other cities.

A.M.A. RESOLUTION

AT the recent meeting of the American Medical Association in Atlantic City, the Section on Preventive and Industrial Medicine and Public Health adopted a resolution, which was later presented and adopted by the House of Delegates, relating to the health protection of the civil population. The resolution follows:

WHEREAS a major factor in the inadequate health protection of the civil population of the nation in peace and war time is the failure to provide for each population unit and each area of jurisdiction, whether city, county, or district, with a full-time, trained health officer and necessary accessory personnel on a merit basis and supported by sufficient local tax resources supplemented by state and, where required, by federal funds, therefore be it

RESOLVED that the Section on Preventive and Industrial Medicine and Public Health urge the Trustees of the American Medical Association to obtain a complete coverage of the population and the area of the United States with full-time, trained health services at the earliest practicable date.

DELAWARE PUBLIC HEALTH ASSOCIATION

THE Delaware Public Health Association held its first annual meeting in Wilmington, Del., June 5, with over 100 in attendance at the all-day sessions. The association is planned as a further step in coöperation between state health and welfare workers and the officers represent five different organizations and the membership seventeen groups.

President—Edwin Cameron, M.D., Executive Secretary, State Board of Health

First Vice-President—G. H. Gehrman, M.D., Medical Director, duPont Company

Second Vice-President—Anna VanW. Castle, Head of the Visiting Nurses Association

Secretary—G. Taggart Evans, Executive Secretary, Delaware Anti-Tuberculosis Society

Treasurer—Roger Murray, M.D., former head of the Wilmington Board of Health

Speakers at the annual meeting included Dr. R. C. Williams, Senior Surgeon, U. S. Public Health Service; Lt. Col. A. G. Compton, M.C., of Fort duPont; Charlotte Heilmann, a representative of the North Atlantic Area of the American Red Cross; Ethelda B. Mullin, Executive Secretary of the Wilmington Family Society; and Richard C. Beckett, sanitary engineer for the Delaware State Board of Health.

NATIONAL HEALTH LIBRARY

THE National Health Library at 1790 Broadway, New York, N. Y., is maintaining a card file of magazine references on health, national defense and war. The file is subdivided under general headings such as child welfare, civilian health, industrial hygiene, mental hygiene, nutrition, social hygiene, tuberculosis, etc. At present there are over a thousand entries and additions are made daily. So far there have been reproduced for distribution five lists of references in relation to child welfare, civilians' mental and physical health, industrial hygiene, nutrition and tuberculosis. A limited supply of these lists is available for distribution on request.

A. M. A. EXHIBITS

THE American Medical Association at its 93rd meeting in Atlantic City, N. J., awarded gold medals in the exhibit to Dr. John C. Bugher and Manual Roca-Garcia of the National Department of Health, Bogota, Columbia, for their exhibit on the means by which jungle fever is spread by mosquitoes.

Special certificates of appreciation were awarded to eleven exhibits from Latin-American republics. There were also a number of certificates of merit and a special certificate of merit given to demonstrations of the Kenny method for the treatment of infantile paralysis.

DRINKING FOUNTAIN STANDARD

THE American Standards Association, New York, N. Y., has announced that new American Standard Specifications for Drinking Fountains (Z4.2-1942) have been adopted by the American Standards Association as of January 14, 1942 (supersedes Z4.2-1935).

The new standard was revised at the suggestion of the Committee on Research and Standards of the American Public Health Association and is essentially identical with the A.P.H.A. standard published in the 1933-1934 *Year Book*, pages 82-83, as the Appendix of the report of the Committee on Plumbing of the Engineering Section.

NEW PUBLIC HEALTH NURSING CURRICULA

THE curriculum in Public Health Nursing in the School of Public Health, The University of North Carolina, Chapel Hill, is now on the accredited list of the National Organization for Public Health Nursing of programs of study in Public Health Nursing for graduate nurses, as are also the curricula at Seton Hall College, Newark, N. J., and the University of Pittsburgh, Pittsburgh, Pa.

13TH ANNUAL MEETING
WESTERN BRANCH, A.P.H.A.

SEATTLE, Wash., was the scene of the 13th Annual Meeting of the Western Branch and related groups, May 26-29. A strong local community under the Chairmanship of Honoria Hughes, with the active support of Dr. Donald G. Evans, Washington State Health Officer, and his staff, provided an excellent physical setting, and a Program Committee under the Chairmanship of Dr. Adolph Weinzirl, Portland, Ore., provided features of outstanding quality. The Western Branch, under the Presidency of Dr. John J. Sippy of California, and under the leadership of W. Ford Higby of San Francisco, had a good year.

The first day provided conferences of state supervisory nurses, of workers in maternal and child health and crippled children's services, in social hygiene, in vital statistics, and in various aspects of the Indian Service.

Unusually representative participation was secured from outside the territory of the Western Branch. The address of Dr. Harry S. Mustard, Director of the DeLamar Institute of Public Health, Columbia University, New York, N. Y., on "The Need for More Adequate Public Health Programs" will be remembered by many in attendance. It will be published in an early issue of the *Journal*. Dr. Albert McCown, Medical Director of the American National Red Cross, Washington, D. C., Dr. George Baehr, Chief Medical Officer of the Office of Civilian Defense, Washington, D. C., Dr. Kenneth F. Maxcy, Professor of Epidemiology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, Marjorie M. Heseltine, Children's Bureau, Washington, Dr. James G. Townsend of the National Institute of Health, Bethesda, Md., Dr. Orlen J. Johnson of the American Medical As-

sociation staff, Dr. Mark V. Ziegler of the U. S. Public Health Service, Chicago, Mary J. Dunn, U. S. Public Health Service, Washington, Dr. Edwin F. Daily, Children's Bureau, Washington, and Dr. Reginald M. Atwater, Executive Secretary of the American Public Health Association, were among participants from other parts of the country, in addition to more than 600 in attendance from the western states and provinces, the Territory of Alaska and other parts of the Western Branch area.

PUBLIC HEALTH RESEARCH INSTITUTE
OF NEW YORK CITY

THE City of New York, on July 1, entered into a contract said to be unique in municipal history with the Public Health Research Institute of the City of New York, Inc., a recently formed, non-profit, scientific institution. The contract is in force for a period of ten years and is automatically renewable for similar periods unless previously abrogated, and provides for the payment by the city to the Institute of \$100,000 annually. The money is to be used by the Institute to carry on fundamental medical research through a staff of competent scientists under the direction of a research council composed of leading authorities in the field of medicine, biology, physiology, nutrition, public health and related fields.

The services to be rendered by the Institute to the City include research and investigation into the control of diseases such as influenza, poliomyelitis, arthritis, degenerative diseases and general physiological problems such as nutrition. Also generally to engage in laboratory experimentation and research in order to develop better and more economical biological products and improve technical procedures for use in combating diseases in epidemics. The Institute will assist the director of the Bureau of Laboratories of the Depart-

ment of Health in matters involving public health research. The City on its part agrees to permit the Institute to use premises now occupied by the Bureau of Laboratories of the Department of Health at the William Hallock Park Laboratory or elsewhere without charge. The results of the Institute's research are to be the property of the City and any discovery of products or methods which may be made by anyone employed by the Institute will belong to the City as soon as made and there will be no further compensation. All patents issued to the Institute or to any of its employees shall be assigned immediately to the City. Unless the City notifies the Institute not less than one year prior to the termination date of this agreement, it will automatically renew itself on June 30, 1952, for a period of ten years.

The Board of Directors of the Institute includes David Heyman, President of the New York Foundation, the Mayor of New York, the Comptroller, Commissioner of Health Dr. John L. Rice, David Rockefeller as vice-president, Edwin F. Chinlund, treasurer, and David Morse, secretary. The research council in charge of all scientific programs is under the chairmanship of Dr. Thomas M. Rivers, director of the hospital of the Rockefeller Institute for Medical Research, New York, now of the Navy Medical Reserve Corps, and Drs. Eugene L. Opie, Henry C. Sherman, George Baehr, Michael Heidelberger and Ralph S. Muckenfuss, Director of the Bureau of Laboratories, New York City Department of Health.

NURSING PERSONNEL POLICIES AND SALARIES

IT has been announced by Alma C. Haupt, R.N., Executive Secretary of the Subcommittee on Nursing of the Office of Defense, Health and Welfare Services, Washington, that, at a recent meeting the Subcommittees on Nursing

and Hospitals, impressed by the shortage of nurses and the increasing needs of the army and navy for additional personnel throughout this year and next, felt that the shortage of graduate nursing personnel in civilian institutions was, in many instances, largely due to personnel policies and salaries.

The committees adopted a resolution calling to the attention of hospital authorities the revised *Manual of the Essentials of Good Hospital Nursing Service*, published by the American Hospital Association and the National League of Nursing Education, with the urgent request that the personnel policies therein be thoughtfully reviewed in relation to the policies effective in institutions under their control in order that graduate nurses may be encouraged to remain in institutional service rather than going into non-nursing work, and that a large number of qualified young women may be attracted to enter schools of nursing.

CLEVELAND FOUNDATION GRANT

SUPPORTING the Cleveland Health Museum in its program to "go to the people" when tire and gasoline shortages prevent people from coming to the museum, the Cleveland Foundation has made a grant which will be used for assisting in construction and installation of health exhibits throughout Greater Cleveland.

Dr. Bruno Gebhard, museum director, suggested that groups interested in obtaining neighborhood exhibits consult the museum. He reported that requests for the "Food for Health" traveling display have become so numerous that duplicates are being constructed.

HANDBOOK OF SCIENTIFIC AND TECHNICAL SOCIETIES

THE National Research Council has announced publication of the 4th edition of the *Handbook of Scientific*

and Technical Societies and Institutions in the United States and Canada. The United States section contains information on 1,269 societies, associations and similar organizations in the natural sciences and related fields contributing to the advancement of knowledge through their meetings, publications and other resources. The Canadian section contains information concerning 143 organizations.

Copies of the *Handbook* can be obtained through the Book Service of the American Public Health Association at the list price of \$4.00.

HERMAN KIEFER HOSPITAL STAFF CHANGES

APPPOINTMENTS were recently made of G. R. Harris, formerly Superintendent of Public Welfare for the City of Detroit, as Hospital Administrator of the Herman Kiefer Hospital; and Franklin H. Top, M.D., as Medical Director. Dr. Top retains his former position as Director of the Division of Communicable Diseases and Epidemiology of the Detroit Department of Health and of the Herman Kiefer Hospital.

PERSONALS

Central States

RICHARD F. BOYD, M.D.,† recently Assistant to the Chief of the Division of Local Health Administration, Illinois Department of Public Health, Springfield, has been appointed Acting Chief of the Division, succeeding **MARVIN F. HAYGOOD, M.D., C.P.H.,†** deceased, who was to have become Chief of the Division of Local Health Administration on July 1. Dr. Haygood had recently resigned as a staff member of the Iowa State Department of Health, Des Moines.

DONALD E. BUX, M.D., of Manhattan, Kans., has been appointed full-time Health Officer of Cherokee County, with offices in Columbus, succeeding

JOSEPH W. SPEARING, M.D.,† who resigned to become Medical Director of the Kansas Ordnance Plant at Parsons.

JOHN A. CARSWELL, M.D., D.P.H.,† has resigned as Deputy Commissioner of Health in the Peoria, Ill., Department of Health, to accept a position as Commissioner of Health, Santa Barbara County Department of Health, Santa Barbara, Calif. He is succeeded in Peoria by **H. V. HULLERMAN, M.D.†**

WILLIAM H. CARY, JR.,* has been appointed as Sanitary Engineer (R), U. S. Public Health Service, and as Regional Engineer in the Office of Civilian Defense, Sixth Region, Chicago, Ill. He formerly served with the Department of Health, Detroit, Mich., as Sanitary Engineer.

WILLIAM C. GIBSON† was recently appointed a First Lieutenant in the Sanitary Corps of the U. S. Army, with orders to active duty at Key Field, Miss. He will be on leave of absence from his position as Sanitary Engineer of the Hillsdale County Health Department, Hillsdale, Mich., and the W. K. Kellogg Foundation, for the duration of the war.

JACQUES P. GRAY, M.D., M.P.H.,* former Health Director of Hillsdale County, a unit of the Michigan Community Health Project of the W. K. Kellogg Foundation, resigned July 1, to assume the position of Professor of Public Health and Preventive Medicine and Dean of the Medical College of Virginia, effective July 1.

A. L. MILLER, M.D.,† Nebraska State Health Director, Lincoln, has announced his candidacy for the Republican nomination to Congress. According to the press, Dr. Miller has stated that he would resign his position to devote full time to his campaign.

* Fellow A.P.H.A.

† Member A.P.H.A.

GEORGE F. MOENCH, M.D.,† has been appointed County Health Director, Hillsdale County Health Department, Hillsdale, Mich. He assumed his position in Hillsdale June 15, following a 5 months' experience as Acting Health Director for Calhoun County occasioned by the sabbatical leave of HUGH B. ROBINS, M.D.,† who has been health director for Calhoun County for the past 5 years.

CLARENCE D. SELBY, M.D.,* of Detroit, Mich., Medical Consultant with the General Motors Corporation, has been awarded the W. S. Knudsen Award of the American Association for Industrial Physicians and Surgeons in recognition for his "most outstanding contribution to industrial medicine."

Eastern States

ROBERT S. BREED, Ph.D.,* Geneva, N. Y., Chairman of the Standard Methods Committee for the Examination of Dairy Products of the Laboratory Section, A.P.H.A., left early in July for Mexico City, to attend a conference on the means of increasing production of needed agricultural products in the Americas. This is the second trip which Dr. Breed has made to Mexico during the current year.

ROSABEL BURCH,† formerly on the staff of the National Office, Girl Scouts, Inc., New York, N. Y., has accepted a position with the Federal Security Agency, Office of Defense Health and Welfare Services, and is located at the Regional Office at 120 Boylston Street, Boston, Mass.

FRANCIS B. CARROLL, M.D., M.P.H., D.M.D.,† is on leave of absence from his position as State District Health Officer, Massachusetts Department of Public Health. He was called on active duty with the Medical Corps

of the U. S. Army on August 1, 1941, and was assigned to the 16th Medical Regiment at Fort Devens, Mass. On February 10, 1942, he was transferred to Fort Knox, Ky., and assigned, under the authority of the Department of Preventive Medicine, of the Surgeon General's Office, as Camp Epidemiologist at Fort Knox.

DR. GEORGE FRAUENBERGER is now Director of the Division of Physically Handicapped Children, of the Department of Health of the City of New York. This position was formerly held by DR. LYMAN C. DURYEA and by DR. VERNON LIP-PARD. As of the 1st of July, this Division became known as the Division of Physically Handicapped Children instead of Division of Crippled Children, the area of responsibility having been widened to include cardiac as well as orthopedically handicapped children. Dr. Frauenberger was formerly Director of Clinics at the Children's Hospital in Philadelphia, Pa., and has had a wide experience in pediatrics, child growth and development.

VLADO A. GETTING, M.D., Dr.P.H.,† of Boston, Mass., recently District Health Officer with the Massachusetts Department of Public Health, has been appointed Commissioner of Health of Worcester, and entered upon his new duties in February. He succeeded PETER O. SHEA, M.D.,† deceased.

IRA V. HISCOCK, Sc.D.,* of New Haven, Conn., who is serving a third five year term of office as member of the Board of Health Commissioners of New Haven, was recently elected President of the Board of Health Commissioners.

ERNEST B. HOWARD, M.D., M.P.H.,† of Boston, Director of the Division of Genito-Infectious Diseases of the Massachusetts Department of Public Health, has been commissioned in the

* Fellow A.P.H.A.

† Member A.P.H.A.

Medical Corps of the U. S. Army and assigned as venereal disease control officer with the Fourth Corps Area headquarters in Atlanta, Ga.

PETER C. KARELEKAS, of Springfield, Mass., Junior Sanitary Engineer from the Massachusetts Department of Public Health, has been commissioned in the Sanitary Corps of the U. S. Army.

ELLIOT S. ROBINSON, M.D., PH.D.,* of Newton, Mass., Director of the Division of Biologic Laboratories of the Massachusetts Department of Public Health, has been commissioned in the Medical Corps of the U. S. Army with the rank of lieutenant-colonel, and is in charge of army laboratory services in the office of the Surgeon General. GEOFFREY EDSALL, M.D.,† of Cambridge, formerly Assistant Director under Dr. Robinson, has been named Acting Director.

CLARENCE I. STERLING, JR., of Westfield, Mass., Assistant Sanitary Engineer from the Massachusetts Department of Public Health, has taken leave of absence to join the staff of the Office of Coördinator of Inter-American Affairs in the Division of Health and Sanitation, under the direction of Brigadier-General GEORGE C. DUNHAM, M.D., DR.P.H.* He has been assigned to Asuncion, Paraguay.

FREDERICK J. VINTINNER,† Director of the Division of Industrial Hygiene of the New Hampshire State Board of Health, Concord, left early in July for Army service at a post in Arkansas.

MYRON E. WEGMAN, M.D.,† recently of the School of Tropical Medicine, San Juan, Puerto Rico, has been appointed Director of Training in the Bureau of Child Hygiene of the Department of Health of the City of New York. Dr. Wegman will also

be connected with the Cornell University Medical College and the DeLamar Institute of Public Health, and his duties will be to provide not only for in-service training of departmental employees but he will have much to do with the training of volunteers in child care work. The last incumbent of this position was ALBERT C. McCOWN, M.D.†

C.-E. A. WINSLOW, DR.P.H.,* Anna R. Lauder Professor of Public Health, Yale University, New Haven, Conn., has been elected President of the National Association of Housing Officials, Chicago. Professor Winslow is Chairman of the Committee on the Hygiene of Housing of the American Public Health Association. C.-E. A. WINSLOW, DR.P.H.,* Anna R. Lauder Professor of Public Health, Yale University, New Haven, Conn., has been designated by the Royal Sanitary Institute of Great Britain as representative of the Institute at the 71st Annual Meeting of the American Public Health Association in St. Louis next October 27-30.

Southern States

CHARLES ARMSTRONG, M.D., Sc.D.,* Senior Surgeon of the U. S. Public Health Service, and Director of the Division of Infectious Diseases of the National Institute of Health, Bethesda, Md., is convalescing at Hamilton, Mont., from a severe attack of tularemia, as announced by *Science*. He was taken ill on May 25, a few hours after his arrival on an official visit to the Rocky Mountain Spotted Fever Laboratory at Hamilton.

DR. JOHN Y. BATTENFIELD, serving for several months with a special trachoma project in Oklahoma under the joint auspices of The National Society for the Prevention of Blindness, Inc., and the Oklahoma State Health Department, has been ap-

* Fellow A.P.H.A.

† Member A.P.H.A.

pointed Medical Associate of the Society, in New York, N. Y. Dr. Battenfield was formerly Epidemiologist and Director of the Division of Preventable Diseases in the Oklahoma State Health Department, and he is President of the Oklahoma Public Health Association.

W. V. BESSONETTE, M.D.,† formerly Director of the Texarkana-Bowie County Health Unit, Texarkana, Tex., is now Director of the Palo Pinto-Parker Bi-county Unit.

LIEUT. EVAN C. BOURDON (M.C.),† Director of the Uvalde-Zavala-Kinney Health Unit, Uvalde, Tex., has been called into military service.

DEAN A. CLARK, M.D., Surgeon in the Division of Public Health Methods of the National Institute of Health, U. S. Public Health Service, Bethesda, Md., has been appointed as head of a Hospital Section organized to carry out the new program, recently announced by the OCD and the Federal Security Agency. Dr. Clark will also head a new Emergency Medical Section in the Public Health Service which will administer the program jointly with the Medical Division.

HESTER CURTIS, M.D., M.P.H., recently resigned as Director of the Division of Maternal and Child Hygiene, of the West Virginia State Health Department, to become Regional Consultant in the Children's Bureau, Washington.

DR. B. H. ESTESS, formerly of the Jasper-Newton County Health Unit, has been made Director of the Central Texas Health Department with offices at Belton, Tex. Dr. R. S. LLOYD replaces Dr. Estess in the Jasper-Newton County Health Unit.

GEORGE A. GRAY, M.D.,‡ for the past year President of the Texas Public Health Association and Director of

the Abilene-Taylor County Health Unit, Abilene, Tex., has been called into military service.

HERBERT HARGIS, recently returned from a year's leave of absence, during which he was assigned by the Pan American Sanitary Bureau to Bolivia, reported recently to the Austin-Travis County Health Unit, Austin, Tex., as Sanitary Engineer.

DR. PHILIP M. HAUSER, formerly Assistant Chief Statistician for Population in the Bureau of the Census, Washington, D. C., has been announced as Assistant Director of the Bureau, by Director J. C. Capt of the Bureau, effective July 1. Dr. Hauser will be in charge of social statistics, including population and housing statistics, vital statistics, the census of agriculture, and statistics relating to state and local government.

DR. LEE JANIS, of the U. S. Public Health Service, has assumed the directorship of the Texarkana-Bowie County Health Unit, Texas.

ALAN C. LOVE, M.S.,† for the past 3 years Sanitary Engineer with the Austin-Travis County Health Unit, Austin, Tex., has transferred to Waco with the new McClennan County Health Unit.

DR. EARL C. NORMAN, now Major Norman, formerly of the Uvalde-Zavala Health Unit, Uvalde, Tex., is now located in Bermuda.

THOMAS PARRAN, M.D.,* Surgeon General of the U. S. Public Health Service, Washington, D. C., was among those receiving honorary degrees at the 176th Commencement of Rutgers University, New Brunswick, N. J.

DR. W. B. PROTHRO, M.D.,† has assumed direction of the El Paso-Hudspeth County Health Unit, El Paso, Tex., replacing Dr. L. T. Cox, now in the U. S. Navy. Dr. Prothro is a brother of E. W. PROTHRO, M.D.,‡ Director of the Corpus

* Fellow A.P.H.A.

† Member A.P.H.A.

Christi-Nueces County Health Unit, Corpus Christi, Tex., and is a graduate in public health from Johns Hopkins University.

GEORGE E. RILEY, M.D., of Jackson, Miss., has been named Health Officer of Clay County, with offices in West Point, Miss.

HORACE M. ROBERSON, M.D.,† Health Director for Bledsoe and Sequatchie Counties, Tennessee, has been named to a similar position in Rhea and Meigs Counties, succeeding HOLLIS C. MILES, M.D.,† of Dayton, who resigned to return to private practice in Cincinnati.

VAN C. TIPTON, M.D.,† formerly Director of the San Antonio City Health Department, San Antonio, Tex., and Field Director of the Division of Maternal and Child Health, is now Lieutenant Commander, stationed in Washington, D. C., with the Division of Communicable Diseases of the Bureau of Medicine and Surgery of the Navy.

Western States

DAVID D. CARR, M.D., C.P.H.,* recently of the Utah State Board of Health staff, Salt Lake City, Utah, has accepted the position of City Health Officer in Topeka, Kans.

W. V. CRUOSS, Ph.D.,† of the fruit products laboratory, College of Agriculture of the University of California, has been awarded the first Nicholas Appert Medal for outstanding contributions to the development of improved food preservation methods, by the Institute of Food Technologists at its recent meeting in Minneapolis.

J. EDWARD DEHNE, M.D.,† of Coquille, Ore., Health Officer of Coos County, has been ordered to active duty with the Army.

VERNON A. DOUGLAS, M.D.,† of Salem,

Ore., Health Officer of Marion County, has been appointed Medical Officer for the Oregon State Defense Council.

ROBERT S. HAMILTON, M.D., has been appointed Health Officer of Clallam County and the city of Port Angeles, Wash., succeeding ALFRED E. EYRES, M.D.,† who recently resigned to take additional work in public health.

ROBERT T. LEGGE, M.D.,† Professor of Hygiene, and Chairman of the Department of Hygiene at the University of California at Berkeley, Calif., retires as Professor Emeritus after 28 years of service. Dr. Legge also was University Physician and Medical Director for the Cowell Memorial Hospital for a quarter of a century.

FRANK MARION MELTON, M.D., of Brandenburg, has been appointed Health Officer for the Unit in Oldham County, Ky.

KARL F. MEYER, Ph.D., M.D.,* Director of the Hooper Foundation of the University of California, San Francisco, has been appointed a member of the Medical and Health Advisory Committee of the American Red Cross.

A. V. NASATIR, M.D., C.P.H.,† formerly Director of the Division of Industrial Hygiene, Los Angeles City Health Department, Los Angeles, Calif., is now a Captain in the Industrial Hygiene Service of the Medical Corps in the U. S. Army. Dr. Nasatir is in charge of the medical program of industrial plants at Ogden, Utah.

MARTHA SHAMBERGER, B.S., M.P.H.,† who recently has completed her work at Yale University, has been appointed as a field worker with the Oregon Tuberculosis Association, Portland, with interests specializing in the field of statistics and public information.

ELMER S. TENNEY, M.D., DR.P.H. (Major, U. S. Army, Retired),† for nearly 7 years Deputy Health Officer

* Fellow A.P.H.A.

† Member A.P.H.A.

of Berkeley, Calif., resigned this position March 31.

Hawaii

PHILIP S. PLATT, PH.D., C.P.H.,* formerly Director, Palama Settlement, Honolulu, Hawaii, has been appointed Associate Director of the Committee on Voluntary Health Agencies, National Health Council, New York, N. Y., of which SELSKAR M. GUNN* is Director. Previous to his service in Hawaii, Dr. Platt was Assistant Director of the New York Tuberculosis and Health Association, and previously Associate Director of the Research Division of the American Child Health Association. He began his new work on July 1.

DEATHS

HENRY DWIGHT CHAPIN, M.D., Professor Emeritus of Children's Diseases at the New York Post-Graduate Medical School and Hospital, died June 27, at the age of 85.

LAWRENCE T. CLARK, Sc.D.,* Director

* Fellow A.P.H.A.

† Member A.P.H.A.

of the Biological Laboratories of Parke, Davis and Company, Detroit, Mich., died recently. According to the newspaper account, Dr. Clark was hit by a falling tree in a thunder storm at his country home near Howell, Mich., on May 29.

ABRAHAM LICHTERMAN, PHAR.D., of New York, N. Y., died recently.

ROY K. FLANNAGAN, M.D.,† Medical Director of the Department of Public Health of Virginia, Richmond, died June 18.

MARVIN F. HAYGOOD, M.D., C.P.H.,† Des Moines, Ia., died recently. He was to have become Chief of the Division of Local Health Administration of the Illinois State Department of Public Health on July 1.

DR. LARKIN E. STARK, Dental Consultant of the Texas State Department of Health, died on May 19, at his home in El Paso.

HENRY GOTTLIEB STEINMETZ, M.D.,† Assistant Director of the Venereal Division, Michigan Department of Health, Lansing, Mich., died on April 22, of anesthetic shock, at the age of 45.

Epidemiological Observations in the Halifax Epidemic*

STAFFORD M. WHEELER, M.D., AND
ALLAN R. MORTON, M.D., M.P.H.

*Instructor in Preventive Medicine and Epidemiology, Harvard Medical and
School of Public Health, Boston, Mass.; and Commissioner of
Health, Halifax, Nova Scotia*

REPORTS of individual epidemics are apt to have little importance as epidemiological contributions unless certain features of the epidemic can be considered in terms of the general behavior of the disease being studied. Unusual opportunities were present in Halifax in the winter of 1940-1941 to study a simultaneous outbreak of *gravis* diphtheria, scarlet fever, and meningococcus meningitis. The common factors underlying this general increase in the prevalence of respiratory diseases were in large part the result of the impact of war on civilian life. Crowding and the rapid overturn of susceptibles in a population are well recognized as proper fuel for the flames of contagion. This is the inevitable result of mobilization and increased industrial activity. In such wartime conditions much can be learned concerning the dynamics of

spread within the crowd and methods of control among civilians and troops.

Much of the material presented was taken from the records of the Dalhousie Public Health Clinic and the Halifax City Health Department. Considerable basic epidemiologic data had been collected by the late Dr. Allan MacLean, head of the Department of Preventive Medicine at the Dalhousie Medical School in Halifax. Dr. MacLean died in October, 1940, just after the start of the Halifax epidemics. Miss Jean Peabody who had assisted Dr. MacLean in his statistical studies gave invaluable assistance in gathering and analyzing data.

The Harvard group which worked in collaboration with the Halifax public health officials consisted of eleven persons of bacteriological, clinical, and epidemiological interests. It was headed by Professor J. Howard Mueller of Harvard who had visited Halifax early in the epidemic to collect strains of the *gravis* organisms for diphtheria toxin

* Read at a Joint Session of the Laboratory and Epidemiology Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

studies. Plans were laid for the larger expedition from Boston when word was received after Christmas that, not only had diphtheria started again to increase in prevalence after dropping off in mid-December, but that scarlet fever and meningitis had assumed epidemic proportions. It should be emphasized that the Harvard Group were in Halifax for only six weeks and the responsibility and credit for the control of epidemic spread and the reduction of mortality rests with the local and Provincial health officials and practitioners.

Before considering the epidemic diseases separately it will serve to bring them into focus by considering Halifax as a background before and after the onset of war, and the environmental factors present which influenced the spread of respiratory contagion.

The population of Halifax according to the Dominion Census of 1941 was 69,326. Even in normal times it has importance as the largest city and capital of a rather sparsely settled maritime province and as a year round open water harbor where large quantities of goods are shipped to and from European ports.

Medical services and hospital facilities in ordinary times may be regarded as adequate. There is a well organized system of clinics run in conjunction with the Dalhousie Medical School. A 45 bed contagious hospital is larger than necessary for the usual winter cases of diphtheria, scarlet fever, and other contagious diseases. Up to October 1, 1940, there was no full-time health commissioner, and campaigns for immunization against diphtheria and other diseases had not been stressed by public health officials. This was perhaps reflected in the rates for diphtheria in previous years which were higher (some 30 to 80 cases annually) than in communities where a larger percentage of children had received toxoid. Housing was sub-standard in certain sections of

the city, notably along the waterfront. In 1938 some 300 buildings had been condemned as unsatisfactory domiciles but new building projects were not yet under way to replace these tenements. In fact, the housing situation in this city had never fully recovered from the disastrous effects of the explosion of 1917.¹

As in the last war Halifax became in 1939 an important winter port for shipping war materials and troops. The civilian population increased under these needs and in addition there was a constantly shifting population of the military, naval, and air forces. Merchant sailors manning convoys from all over the world converged here in large numbers. Ample opportunities can be seen in such an environment for the introduction of infection and its rapid exchange.

After the epidemic had started a severe strain was put on local hospital and medical facilities. Two additional hospitals were opened up for the overflow from the contagious hospital and, in spite of its extra beds, at one time in the winter 73 patients were being taken care of in this 45 bed institution. At least one-fourth of the doctors with active practice were in uniform and, for the same reason, public health and bedside nurses were equally scarce. However, the reorganization of the health department with a full-time commissioner took place in time to allow for greater effect from public health activities. This was especially important in the coördination of military and civilian control measures.

In addition to the three epidemic diseases, diphtheria, scarlet fever, and meningitis, there were sharp epidemics of other respiratory diseases, notably influenza and measles, in the late fall and early winter. The influenza was mild and not followed to any extent by post-influenzal pneumonias and deaths. The diphtheria was the most interesting in that it is the first recorded extensive

outbreak due to the *gravis* strains on this side of the Atlantic. Also, diphtheria with its specific treatment, prevention, and gauge of susceptibility is a rich field for epidemiological study and deserves consideration in greater detail.

The incidence among civilians in the 12 months from July, 1940, to July,

decline in rate for diphtheria in the 10-14 year age group is a result of relatively complete immunization among these school children; at any rate a similar decline is not evident for scarlet fever, which is also abnormally predominant in the older ages. More differences in the behavior of meningitis

TABLE 1

Civilian Population Halifax 1940-1941
Diphtheria, Scarlet Fever, and Meningococcus Meningitis Cases
*Attack Rate per 100,000 Population **

Age Groups	Diphtheria	Scarlet Fever	Meningococcus Meningitis
0-4 years	1,300	1,225	575

55-59	168	...	42
60+	138	35	35
Attack Rate at all ages	935	871	164

* Age specific attack rates based upon age distribution of population at census of 1931 and total population of 69,326 according to the Dominion Census of 1941.

NOTE: The Dominion Census figures are probably incomplete. Sugar ration cards issued place the population at over 100,000, which would give correspondingly lower rates at various ages for the three diseases.

1941, was 649 cases of diphtheria with 24 deaths, 605 cases of scarlet fever with no deaths, and 114 cases of meningococcus meningitis with 16 deaths. Among these meningitis cases were individuals from elsewhere in the province who were hospitalized in Halifax. The peaks of greatest incidence for diphtheria fell in November, and for scarlet fever in March, as is to be expected in these latitudes. Relatively little meningitis appeared until early in December. In contrast to diphtheria and scarlet fever there was very little indication of concentration of meningitis cases in any one area, and only one instance of multiple cases in a family was recorded.

Table 1 gives the three diseases by attack rates at different ages. The high incidence of diphtheria among civilians in older ages will be discussed more fully later. It is suggested that the

as compared with scarlet fever and diphtheria are revealed in this table. The peak of incidence for meningitis is definitely in the preschool children, with a drop in adolescence followed by a rise in the adult years. This might be attributed to greater opportunities for exposure among adult male laborers who constituted the greater number of cases in these age groups. Females were definitely in the majority among adults in the other two diseases.

The scarlet fever was extensive but mild both among civilians and the armed forces. The characteristics of the scarlet fever were so similar to the diphtheria in selection by age, sex, secondary cases, occupations, and geographical distribution as to suggest that the same factors which helped to spread the diphtheria bacillus were operative on the hemolytic streptococcus. Cases

TABLE 2

Halifax Diphtheria 1940-1941
Complications and Deaths Compared to Liverpool (Shone, et al., 1939)

Number of cases	Liverpool			Halifax Gravis

% Hemorrhage	0.3	2.1	1.6
% Nasal (Severe Epistaxis)	11.0

of scarlet fever and other streptococcus infection combined with diphtheria were noted, but there was no constant association of streptococcus infection with the bull necks and other severe local pharyngeal lesions of diphtheria. Throat cultures on scarlet fever patients and contacts revealed a predominant strain classified as type 19 by the Lancefield precipitin method. This strain was easily recognizable but, because of weak agglutinins, was hard to classify as to serological type in the field by the Griffith method, although independent typings in Ottawa, Boston, and New York suggested that, had agglutinations alone been relied upon, this would have been called a type 17. This is not an indictment of the slide agglutination method of Griffith, but suggests one of those unusual strains with agglutinating and precipitating antigens belonging to different types as have been reported by Lancefield.² With a more easily typed epidemic strain and highly type-specific antiserum the method should prove helpful in separating out carriers of epidemic types from those carrying less dangerous Group A strains. This is particularly valuable in army and navy cantonments where one case of scarlet fever may otherwise tie up much of the complement of a ship or barracks.

Gravis diphtheria seems to have been an imported infection in Halifax. The first case suspected of being caused by

this strain appeared in September, 1940. The patient was one of the crew of a Norwegian tanker. He was followed by more cases from Norwegian sailors off a whaling ship anchored next to this tanker in the Basin. Some of these men developed symptoms ashore in a Salvation Army Hostel but within 24 hours of leaving their ship. More cases followed rapidly from the waterfront area and it was soon apparent that Halifax was not only dealing with an unusual number of cases but that the clinical severity of these infections was greater than usual. The infecting organism was identified by fermentations and characteristic colony appearance on blood tellurite medium as the *gravis* strain.* A small outbreak at a summer camp two months before had been identified as caused by the *mitis* variety, which suggests that the later epidemic infection was imported from sources outside of Halifax. The fact that this was exclusively a *gravis* epidemic does not necessarily imply severe infection. Observations vary from the high mortality found in Leeds⁴ and by German observers to a position somewhat more virulent than *mitis* and less severe than

* Mueller³ has shown that the Halifax *gravis* strains are resistant to the inhibiting effect of small amounts of iron on toxin production. This ability to produce toxin in the presence of iron compounds in a concentration similar to that found in the local tissues of the pharynx may be associated with the rapid spread and relative severity of the diphtheria in Halifax.

diphtheria caused by the *intermediate* strains as revealed by Shone⁵ in Liverpool. Table 2 shows a comparison of the Halifax cases with the series reported from Liverpool. The Halifax cases resemble *mitis* infection in the high incidence of laryngeal diphtheria and deaths were certainly fewer here than in most recorded outbreaks of *gravis* diphtheria. However, doctors in Halifax who were familiar with the clinical picture of diphtheria in that locality were in agreement that the disease in the present epidemic showed more extensive membranes and a higher proportion of septic and toxic complications.⁶ The low case fatality rate may be explained in part by the abnormal age distribution, with a high percentage of cases in the older age groups. If the Halifax case fatality rates by ages are weighted by a normal percentage age distribution of cases, as for instance Massachusetts cases from 1918 to 1929, the expected deaths are half again as many as were observed. In other words, as the peak of greatest incidence of

cases shifts to older age groups it travels away from the high case fatality rates of infancy and gives an apparent mildness to the disease, as shown by a decrease in the number of deaths.

In the first stages of the epidemic the age distribution was normal. In December there was a decline in cases after the peak of November, followed by a rise in January, when there was a marked shift to the older age groups and the female sex. This dropping off of younger cases coincided with relatively thorough immunization of the school age population. The epidemic was maintained through June, when 50 civilian cases were reported, and the indications are that the epidemic is not yet burned out and that there is still a large reservoir of susceptibles in the unimmunized population.*

The curve of incidence among the armed forces followed or led the civilians very closely. Study of the records suggests that the epidemic started in the Norwegian merchant marine and quickly spread among the civilians in the waterfront area. Cases in the services appeared first chiefly in the Royal Canadian Navy personnel, whose contacts would be greatest along the waterfront. As with the civilians, there was a decline over the period of the Christmas holidays, followed by an increased incidence in January. Figure 1 shows how the forces climbed steadily in percentage of total cases in the given month, followed by the adult females, whereas the older civilian males and children of both sexes dropped off. Figure 2, cases of diphtheria by age and sex, shows even more markedly the preponderance of female cases between the ages of 15 and 30 years. History of contact with the forces was more than plentiful among diphtheria cases in women between the

FIGURE 1

* This is borne out by more recent figures on diphtheria in Halifax. From July 1, 1941, to April 30, 1942, 609 cases of diphtheria have been reported.

FIGURE 2

ages of 15 and 30. One cannot escape the conclusion from the study of available data that in its later stages this epidemic was maintained by the exchange of infection between the soldiers, sailors, and aviators and their wives or sweethearts in the town of Halifax. This does not preclude the possibility of reservoirs of infection among carriers and missed cases of nasal diphtheria in the preschool age group but, in the opinion of the authors, this was not the principal source of infection in the Halifax epidemic.

As might be expected of any community with areas of overcrowding and poor housing, Halifax had a concentration of cases where housing conditions were at their worst. A map showing the distribution of tuberculosis deaths in Halifax in recent years reveals a concentration of cases in the same areas as the diphtheria spot map. Here one also finds the largest number of multiple cases in houses and families. A carrier survey of over one thousand Halifax school children in February showed rates as high as 30 per cent for carriage

of the diphtheria bacillus in one of the schools of this district, and 20 per cent in another. Not a single carrier of virulent organisms was found in certain of the schools in the better residential district. The average percentage of carriers among school children and clinic populations in the February survey was 11 per cent. In June, 840 school children were cultured and only 2 per cent were found to be carriers. Although there were 50 cases reported in this month, they were chiefly among adults.

Control measures included Schick surveys, isolation of carriers, and the establishment of clinics for active immunization against diphtheria. This was carried out with fluid toxoid, 3 doses at 3 week intervals, followed by a repeat Schick test in 3 months. As the attendance at toxoid clinics grew to hundreds and, for a brief period, even to thousands, practical considerations made it necessary to establish the following routine: All children under 12 years received toxoid at their first visit without regard to primary Schick test or sensitivity test. Older clinic patients received a Schick test in one arm and in the other arm 1/10 ml. of toxoid diluted 1/10 intradermally. This "Moloney Test" of sensitivity to bacterial proteins should be read in 48 hours, but for administrative reasons these patients were instructed to return in 5 days. At that time their Schick tests were read and, if positive, the first dose of toxoid was given. If there was a history of erythema or induration at the site of the Moloney test, toxoid was given in higher dilution and more frequently.

Toxoid reactions occurred only rarely among the older patients but were at times severe, with headache, swelling of the arm, and fever of short duration. Comparative studies on toxoid reactions from materials prepared at the Connaught Laboratories in Toronto and from other sources showed no signifi-

TABLE 3

10-14	45	24	69
15+	51	1.7	52.7
All Ages (adjusted)	44.8	7.4	52.2	4.6	58‡

* The figures are based on 8,783 primary Schick tests and 8,417 completed immunizations.

† The rate of natural immunization during the epidemic is not considered in this table. Evidence from Schick testing at different times between September, 1940, and June, 1941, is not conclusive as to the extent of natural immunization at the subclinical level.

‡ Includes approximately 1.2 per cent of the population who have developed clinical diphtheria within the past 6 years.

cant difference in percentage of reactions. With proper precautions by sensitivity tests it was felt that immunization of older individuals with toxoid was a safe and advantageous method. Credit is due to the efficient follow-up work of the public health

nurses that 92 per cent of the patients immunized completed their full course of 3 doses of fluid toxoid, and 70 per cent of those who started immunization completed their course and returned for a repeat Schick test. Shift to Schick-negativity among those immunized was

* Period of observation between July 1, 1940, and June 30, 1941. Eighty-six per cent of the attendance at the toxoid clinics was in the 6 week period between October 20 and December 1, 1940.

† Based on 42 per cent estimated Schick positives in population. See Table 3.

over 95 per cent, according to tests given 3 months after completion of immunization.

An attempt was made to determine the immune status of the community and the results of immunization. It has already been shown that the case incidence among school age children decreased as the epidemic progressed. Table 3 shows the levels of immunity estimated for different age groups in the epidemic year. Note the rise in immunes in the 10-14 year age group. Another method of evaluating the effect of toxoid is to study the diphtheria occurring in immunized children compared with the rates for the estimated unimmunized susceptible population. Table 4 shows a comparison of cases among those receiving 3 doses of toxoid in the epidemic year with those having no history of previous immunization. From this evidence it would seem that the effect of active immunization with fluid toxoid is to protect against diphtheria after a relatively short interval. The transient protection afforded by passive immunization was seen in four contacts who developed diphtheria within a month of receiving 10,000 units of antitoxin prophylactically. A small clinic was established to Schick test, culture, and immunize contacts of cases. Even among the Schick-positive contacts, toxoid was employed in preference to

FIGURE 3

prophylactic antitoxin to avoid unnecessary sensitization to horse serum.

The level of natural immunity to diphtheria in the population can be seen in Table 5 of Schick test results in previously unimmunized individuals by age and sex. The relatively higher percentage of negative Schick reactions among males than females at all ages is consistent with findings reported elsewhere as reviewed by Doull.⁷ The explanation for this phenomenon is obscure. The generally low level of immunity as indicated by the Schick

TABLE 5

Cleveland, Ohio	Urban	1938	960	21	26.9	2.1

* Only 2 cases of diphtheria and no deaths reported from Kingston in the 6 year period, 1933 through 1938.

† These rates are from reported cases and deaths from diphtheria in Cape Breton County, Nova Scotia, in 1938 and 1939. For Glace Bay the average rates for the 10 year period, 1928 to 1939, are: morbidity, 27.0, and mortality, 5.8. The case fatality rate from these figures is 21 per cent which indicates incompleteness of reporting at that time. The more recent figures from the county in which Glace Bay is situated are considered a better index of the prevalence of diphtheria at the time of the survey.

test survey cannot be attributed in this instance to lack of experience with diphtheria in the past. Table 6 is a comparison of the Schick test levels in previously unimmunized school children in Halifax with surveys on a similar basis from other parts of North America.⁸⁻¹⁴ Previous experience of the community with the disease, the attendant carrier rates, and the degree of urbanization are undoubtedly factors in determining the levels of natural immunity, but from the results shown in Table 6 this immunization seems to be more easily accomplished in the south than in northern climates.

The high age distribution of cases is also usually a characteristic of northern diphtheria.¹⁵ In Figure 3 the age specific attack rates of Halifax diphtheria in the present epidemic and for the 5 years, 1934 to 1939, are compared with figures for Baltimore from 1923 to 1928. The two Halifax curves are similar, suggesting a permanent factor influencing the age distribution of cases. However, no such preponderance of adult females was seen in cases before the epidemic and the percentage in older age groups was not so great.

In conclusion, certain implications from this city's experience with epidemic disease should be emphasized in order to avoid, if possible, a similar experience in other communities.

1. The necessity for decent housing in defense areas.

2. To apply to civilian populations and to troops all the effective methods in our knowledge for the specific prevention of disease.

This is especially pertinent with reference to diphtheria. In this disease immunity decreases as one goes north as well as out in the rural areas. Likewise, it becomes less and less of a childhood disease. With this in mind, and particularly with reference to the United States Navy whose contacts are many in the north Atlantic, it is our opinion that every soldier and sailor should be Schick tested, and immunized if found to be susceptible.

Need of More Adequate Public Health Programs in the Several States*

HARRY S. MUSTARD, M.D., F.A.P.H.A.

Professor of Public Health Practice and Director, DeLamar Institute of Public Health, College of Physicians and Surgeons, Columbia University, New York, N. Y.

WITH the clearing of the war situation, the urgent next step of public health administration in the United States is to provide effective local public health service, under governmental auspices, in every community of the nation. This statement is purposely bald, point blank, unadorned, and unqualified. There is deliberately omitted from it any recognition of the difficulties to be encountered, any reference to how the service is to be rendered, and any suggestion as to who shall pay for it. Nor, for the moment, is it desirable to go into details as to the quantity or quality or inclusiveness of service. The essential point to be emphasized is that nearly one-third of the population living in almost one-half of the counties of the United States are without effective tax supported, full-time local health services.

In most human affairs, a historical approach contributes to an appreciation and understanding of a current situation. Generally, too, it provides some insight as to measures to be employed in the future. For these reasons, it seems worth while to view this whole

problem of public health service in the United States in perspective. When this is done there appear to be four fairly well defined periods: First, colonial and through 1868; second, 1869 through 1913; third, 1914 through 1934; and fourth, 1935 to the present. While these periods are not so sharply separated from one another as dividing dates might imply, they are rather definite as to trends. Each has within it certain significant events; each ushered in or brought to a close some concept or tendency or cycle; each offers a background against which the present may be placed.

FIRST PERIOD, COLONIAL THROUGH 1868

In this period people lived locally, their problems were local, and they acted locally. Unpleasant odors assailed the citizen, local authorities were bombarded with complaints, and, finally, in one community and then in another, laws were enacted or regulations promulgated, prohibiting nuisances and providing for their abatement. Or the factor precipitating action might have been an epidemic. Thus, in Colonial days, when yellow fever or smallpox made its appearance, the Assemblies permitted the various localities to organize boards of health for urgent action. Many such boards of health came into existence, too, because of cholera epidemics which occurred in the United States, beginning

* Read before the Western Branch American Public Health Association at the Thirteenth Annual Meeting in Seattle, Wash., May 27, 1942, and published by request of the Western Branch.

AUTHOR'S NOTE: As a matter of record it should be noted that Dr. Haven Emerson, though in no way responsible for the opinions expressed in this paper, has for some time been active in emphasizing the urgent necessity of providing adequate health service for every community in the nation.

in 1832 and continuing intermittently for nearly half a century. In the circumstances, it was quite natural that local boards of health were organized long before state boards of health: Petersburg, Va., had a board of health in 1780, but the State of Virginia did not organize its board until 1872. Although the records are not as orderly and complete as one might wish, it would seem that Philadelphia had a board of health in 1793, Pennsylvania in 1885; New York City in 1796, the State in 1880; Baltimore in 1798, or earlier, Maryland in 1874; Boston in 1799, and Massachusetts in 1869.

This observation that local conditions and actions preceded central administration is also to be seen in the development of national health services. It will be remembered that the beginnings of what we now call the United States Public Health Service are to be found in a Congressional Act of 1798, which provided for the furnishing of medical relief to merchant seamen. This Act, however, did not provide for any over-all administration. Instead, each collector of customs appointed a local physician and made such arrangements as were needed for hospital care. To support this medical relief the master of every American ship arriving from a foreign port was required to pay to the collector of customs of the port entered, twenty cents a month for each seaman in his crew. This amount was deducted from the seaman's wages. Under this act of 1798, money collected in one port could not be utilized for medical care of seamen in another port, which again emphasizes that the activity was essentially on a local basis. Then, in 1799, a new act was passed providing that money collected in one port might also be spent for care of disabled seamen in a state adjacent to the one in which it was collected, except in relation to New Hampshire, Massachu-

setts, and Connecticut. After three years, these limitations were removed, and money collected for this purpose went into a general fund, to be used anywhere in the United States for disabled seamen. It was not until 1870, however, that a central administrative agency was provided, and at that time the care of disabled seamen was organized on a national basis. The same transition from local to national status may be observed in the development of maritime quarantine. Although Congress had, as early as 1796, passed laws extending federal aid in the enforcement of local regulations relating to ship quarantine, over three-quarters of a century passed before Congress enacted (1878) a law making this a federal responsibility. Even so, it was not until 1921 that the last local port quarantine station was taken over by the U. S. Public Health Service.

From even so brief a review, it is seen that the essential characteristics of this period were: (1) public health facilities arose only to meet situations where something had to be done, as in epidemics, nuisances, and sick seamen; (2) such measures as were taken were taken by local units of government, or for individual local service. There was no thought of wide-scale planning, over-all administration, or compulsion.

SECOND PERIOD, 1869 THROUGH 1913

In 1869, Massachusetts established the first* state board of health and California organized the second in 1870. By 1913 all states in the Union had similar boards. Quite naturally each board on its formation had to go through a process of adjustment and consolidation before it could hope to function effectively. Most of them did this reasonably satisfactorily and de-

* This is conventionally accepted, though Kerr and Moll, in *Public Health Bulletin No. 54* (August, 1912), list Louisiana as establishing such a board in 1855.

veloped activities and programs which units smaller than a state could not well undertake. However, while these state boards of health struck a note of new significance in public health administration, they made but little contribution to the development of local health service. It was at first left largely to each unit of government to decide whether or not it would take advantage of legislation which permitted it to provide the community with a board of health and a part-time health officer. Actually, many state boards of health developed the philosophy that from a central office they could render to communities whatever local health service might be necessary. In any event, in the early part of this period local health services remained essentially as they were before the organization of state boards of health: A given jurisdiction might or might not have a local board or part-time health officer. Then in one state and another legislation which had previously left this matter to local option was made mandatory, and by the end of the first decade of this century, units of local government were required in most states to meet these more or less primitive standards.

In the meantime, however, knowledge as to public health matters had increased considerably and the provision of a board of health which met only in emergencies or occasionally, and the services of a part-time health officer whose principal duties were to attend the sick poor and occasionally to engage in vaccination against smallpox, were recognized as being inadequate. With this in mind, thoughtful citizens in many communities organized local effort to meet health needs that were quite obvious but completely neglected by the governmental agencies, and there arose many voluntary health agencies. But the influence of these efforts reached little further than their own borders,

and most state health departments (or boards) remained lackadaisical as to local health work.

Then two new forces entered the field on somewhat of a national scale and exerted definite pressure for governmental provision of local health service. One was the Rockefeller Sanitary Commission, particularly interested in the study and control of hookworm disease, and the other was the U. S. Public Health Service, which in this area of its activities was especially concerned with the problem of typhoid fever. It may be said that as a result of the work of these two agencies there later developed the present concept that the first requisite in public health work is a tax supported local organization competent to render routine direct health service.

Late in this period, too, one of the most significant events in the history of the public health in the United States occurred in the State of Washington. This was in Yakima County, when Lumsden, of the Public Health Service, investigated the typhoid situation, which, in turn, led to the organization of a local governmental health service designed to cope with the problem. Perhaps in the nation there are one or two other counties which have prior claims to what may be called the first full-time county health department, but so far as is known the establishment of health work in Yakima County in 1911 is the first instance where, through coördinated federal, state, and local effort, a new standard of local health service was put into effect.

There is another episode in the development of federal health activities which is significant: the National Board of Health. As has already been said, it was in 1870 that central administration was provided for the Marine Hospital Service, and in 1878 that maritime quarantine was made a federal responsibility. In the meantime

cholera and yellow fever epidemics had so disturbed the nation that there arose a demand for coördinated action. Particularly active in urging this were the leaders of the newly formed American Public Health Association. In response to these demands, Congress, in 1879, created a National Board of Health. But this concept of a national responsibility for health, forecast by providing central administration in medical relief and maritime quarantine, was not sufficiently ingrained to sustain a National Board of Health. That organization was quite active for about four years, remained dormant for another ten, and went out of existence by legislation enacted in 1893. Nevertheless, the mere fact that such a board was created demonstrates what happens when the health problems of a large number of localities are added together.

Viewed in retrospect then, this period from 1869 through 1913 was one where in its earlier years legislation which had previously been permissive as to local boards of health and part-time health officers, became mandatory in many states. It was the period, too, when over-all administration of health matters was introduced in both state and federal governments, and of stabilization and consolidation of state health organizations. Toward the end of the period, there was a promise of interest and aid to state and local health work from the federal government and from a great foundation. Finally, there was another implication: a faint stirring of interest in providing more adequate and effective local health service.

THIRD PERIOD, 1914 THROUGH 1934

Of particular interest and significance in this period is the fact that, in 1914, the U. S. Public Health Service spent some \$18,000 in field investigations in four counties, and continued this type of work during the next few years; that, in 1917, Congress provided

an item of \$150,000 for "special studies of and demonstration work in rural sanitation." This amount was considered a staggering sum in those days, but what is more interesting is this: The Act stipulated that "no part of this appropriation shall be available for demonstration work in any community unless the state, county, or municipality in which the community is located agrees to pay one-half the expense of such demonstration work." This not only forecast a higher standard of local health work through federal aid, but also required state or local participation, or both, wherever federal funds were used. In a similar manner the Rockefeller Foundation, and later the Commonwealth Fund, and other foundations, made significant and substantial contributions to the extension and improvement of local health service, and constantly observed the principle of requiring local participation in the financing of such work.

The response to this stimulation was encouraging. State health officers responded most gratifyingly. Many of the state legislatures made appropriations specifically for aid in the development of local health services, and in a number of states, where local units of government had no authority to expend funds other than for a part-time health officer, permissive legislation was enacted, making it possible to provide a higher standard of service. As a result of this new interest, and with continuing federal and foundation grants-in-aid, the number of communities with full-time local health service increased fairly steadily for a number of years: From about fourteen in 1915 to nearly five hundred by the end of 1929. However, this increase was not maintained during the next five years, for, whereas on January 1, 1931, there were 557 counties, townships, or districts having full-time health service, the number on December 31, 1934, was 540.

The early part of this period may be called the days of giants in public health administration. It was a time of vision, of action, of great accomplishment. Today's leaders in public health were tried and seasoned, and perhaps somewhat fixed in the mold. In the period as a whole, there was strengthening of state boards and departments of health, there was an expansion in the scope of the public health program, an improvement in the precision of local health administration. It is exceedingly important and significant, too, to note that public health history was tending to repeat itself: in the Colonial period legislation was enacted which permitted local units of government to provide themselves with primitive health organization if they chose to do so. In the next period, though some states took no action, many, through revision of existing laws, made the permissive legislation mandatory, or enacted new legislation to the same end. Now, in this period comes permissive legislation for a higher type of health service. Logically and historically, this new-standard permissive legislation will eventually be followed by laws requiring more modern and adequate health service in all units of local government.

FOURTH PERIOD, 1935 TO 1942

The discussion now enters upon the present period, its accomplishments, its trends, its significance, its deficiencies. The event which separates this period from the one preceding is the enactment of social security legislation by the Congress of the United States. This was in 1935. The Act carried two sections of unusual significance. These were Titles V and VI. Through the former, the Children's Bureau received \$6,650,000 to aid in the development of state and local health work in the fields of maternal and child health and care of crippled children. Through Title VI,

the U. S. Public Health Service received some \$8,000,000, for similar aid to state and local governments in the general field of public health. Thus, where previously, federal grants for the country as a whole had been limited to comparatively small sums, the amount available under this new legislation was suddenly raised to millions of dollars. There was a rather rapid increase in the number of local health organizations, an improvement in their quality, an expansion and strengthening of state health departments—perhaps too much of the latter at the expense of the former. Emphasis was given to special problems and programs, and in general public health work in the United States was greatly accelerated. Measuring progress in terms of population provided with full-time local health service, it is found that as of June 30, 1941, approximately 70 per cent of the people of the United States were so reached. Using the county as a unit of local government, the record shows that, as of the above date, in 1,669 counties there was provided full-time official health service. One might say that this is excellent progress, and in many ways it is. But there are nearly 3,100 counties in the United States, and only a little more than half have developed full-time local health service; and there remain some 40,000,000 citizens whose governments have made available to them no better local health service than was possessed by their ancestors. Very few states and no federal health agencies have laid down any forehanded, organized effective plan for remedying this situation quickly and completely.

In the immediately preceding sentence is, perhaps, to be found the greatest barrier to the future of public health development in the United States. The solving of this problem will not be easy, and any plan to provide reasonably adequate public health service to the citizens of every commu-

nity in the country must consider three essential elements: First, it must recognize the difficulties; second, it must provide measures for overcoming them; and third, it must insure for each local jurisdiction or combination of local jurisdictions public health services which will apply to the maximum the present and future public health knowledge.

Of the known deterrents to the providing of effective local health service in all communities in the nation, the following are probably the most important.

1. Failure of most state health officers to be acutely concerned with the large proportion of the population not reached by efficient local health service.

2. Acquiescence, by most state health officers, in the belief that local health service in all jurisdictions in the state can be brought about only gradually and by opportunism and compromise.

3. The fact that in most states the decision to engage upon an efficient health service is a matter of option, to be decided upon by local government.

4. Authority to expend funds for public health purposes is vested in units of local government unsuitable for sound and economical public health education. This is seen more frequently where the township is the unit of local government, but not all counties are satisfactory in this regard.

5. Inadequacy of local financial resources in local units of government.

6. Too small or too scattered population in the local units of government.

7. The inadequacy of state subsidies for aid in providing health service in local units of government.

8. The absence of any clearly-cut formula for effective distribution of state and federal public health funds to local units of government.

9. A tendency of many state health departments to utilize federal grants for building bigger and better central state organizations.

10. The attitude and policies of some voluntary health agencies and physicians, of many part-time health officers, and, occasionally, of strategically placed politicians in the various states and communities.

11. Failure of federal health agencies to make granting of funds contingent upon submission of over-all plan by the state for application of such federal funds in all local juris-

dictions. States receive federal grants on the basis of total population and total needs, but there is no requirement that the benefits of these funds be equally distributed to the total state population.

12. The enticing but treacherous comfort of *laissez faire*.

13. A combination of two or more of the above deterrents.

No sane person would claim that these difficulties are not real or that they may be overcome without effort. On the other hand, only a defeatist would contend that they are insurmountable. It is rather obvious that in spite of the large federal funds made available within recent years, the goal of reasonably adequate health service in all communities is still far from attainment. Further, it must be recognized that those local jurisdictions which now possess such service are generally the ones which occupy favorable economic situations. The units of government to be reached in the future are in the main local jurisdictions which are sparsely settled or very small or very poor or very remotely located, or very smugly stewing in the juice of their own tradition. The old basis of exhortation and salesmanship does not appeal to them. They can be reached only by a new and different approach.

No one may lay down in detail any scheme which would be applicable in all the states, but three necessities stand out clearly if all communities in the nation are to be supplied with local health service. The first is that federal subsidies for health work be granted to a state only if that state submit an over-all plan which will insure effective local health service in each of its local jurisdictions. The second necessity is mandatory state legislation, requiring that every unit of local government participate financially in providing its citizens with an effective local health service. The third necessity is for state legislation which, for purposes of public health administration, provides com-

binations of local units of government so that service may be performed on an economical basis and reasonably completely. As concerns the federal requirement, it would not appear to be either unreasonable or unconstitutional for the federal government to exercise its power to the end that all the citizens in the several states receive the benefits of these federal funds, thus preventing benefits from being distributed in a haphazard or opportunistic manner. Possibly this requirement could be provided by regulations of the Surgeon General and the Chief of the Children's Bureau in relation to the administration of Titles VI and V of the Social Security Act. Certainly it could be effected by amendment to these sections of that Act. If prompt action is to be obtained there must be some time limit for compliance with such a federal requirement. If and when the plan is put into effect, it might be required that a state, to be eligible to receive a grant for improvement of state and local health service must, by previous legislative enactment or by enactment of the next coming legislature, provide the necessary legal instrument for insuring state-wide local health service, and further provide a state appropriation which when added to that state's fair share of federal funds, would be sufficient in amount to provide such effective local health service. Obviously, it would contribute to ease and economy of federal and state administration and would get rid of much confusion and duplication of personnel and effort if, in this process of federal planning, the amazing and distressing separateness of the U. S. Public Health Service and the health activities of the Children's Bureau could be corrected.

In connection with mandatory legislation in states, many will say that the citizens and the assemblies of the states would balk at a law requiring an effec-

tive level of health service in all communities. Probably in some states this would be the case. However, faced with the loss of federal funds unless such funds were used for the benefit of all citizens of the state, probably only a few legislatures would remain adamant, especially as laws requiring a decent local health service would on their merits meet with popular support. And such legislation would be no new thing in state government. Every community is required to have a sheriff or police, courts of law, and a school system, among other things. Also, in the history of the development of public health administration in the United States, as has been recounted, the natural sequence of events has been, first, permissive legislation, the gradual acceptance of this permissive legislation by a number of localities, and then mandatory legislation for all localities. Local government units, thus, at first chose whether or not they would have a part-time health officer and a board of health. Later they were required to have these things. At present local governments choose whether or not they will organize effective local health service. The time has come to follow precedent and make the provision of effective local health service a requirement. The mandatory legislation in question, however, would in some way have to define what constitutes effective local health service, perhaps in terms of per capita expenditure for such services. Also, it would be necessary to provide some formula whereby the amount of funds provided by each local government of a state for local health service would be proportionate to the financial resources of that jurisdiction. Possibly it might be required that each jurisdiction set aside a certain proportion of its tax income. Further, in such legislation it would be necessary to provide that the local unit of government, having made the necessary appropriation, would have

assurance that the state health department, through funds derived from the state legislature and other sources, would be required to subsidize each local budget in sufficient amount to build local health service up to that level previously defined as effective. The exact provisions and requirements in legislation of this sort would naturally vary from state to state, but so long as the legal instrument provided

brought the necessary results, such variations would not be detrimental but rather the contrary.

It is recognized, of course, that the problem of winning the war must take precedence over all other things. On the other hand, it is not too early to give some attention to this matter and to lay careful plans which at some early post-war period may be acted upon swiftly, boldly, and compellingly.

Wartime Public Health in Alaska*

COURTNEY SMITH, M.D., DR.P.H.†

U. S. Public Health Service, San Francisco, Calif.

PUBLIC health problems in Alaska, generally speaking, are the same as those throughout the United States, but with many added complications related to the unusual in geography, population distribution, racial composition, weather, transportation, and communication. To these complexities add those of a six year old infant public health organization attempting to establish itself in a Territory which is made up largely of individualists, not too receptive to new ideas regarding public health improvement, and you have a working situation both intriguing and at all times stimulating. When, at last, there appear to be some signs of acceptance of the fundamentals of a public health program, suddenly double the population, add for good measure a war, which is very likely to be fought right at your front door—then you can realize the extent of the task which we face. For one who complains of the monotony of a smooth running health department, a term of service in Alaska in these times would prove at the least diverting.

The Territorial Department of Health furnishes generalized public health services to all people of Alaska, regardless of race. Acceptance of the whole public health program by Alaskans has been slow and, in many cases, reluctant. No city maintains a full-time health de-

partment or health officer. Public health laws are loosely drawn and in many instances sadly outmoded and obsolete but, in spite of this, the public health nursing programs in the various towns are well supported. Another indication of the interest of Alaskans, when sold on a proposition, is evidenced in their support of the tuberculosis control program. Their contribution to the voluntary Alaska Tuberculosis Association for the past three years has been 10 cents per capita, one of the most generous of any people under the American flag. In fact, this is the highest of any state, with the exception of Delaware.

I believe that Americans generally, and particularly those on the Pacific Coast, have a good mental picture of the geography and population make-up of Alaska, but there are some features, particularly as they relate to the war effort and bear on public health problems, which deserve a few brief comments.

The first of these is the immensity of the Territory. With its almost 600,000 square miles of land area, it is one-fifth the size of the whole United States. Spread these miles over with generous portions of high mountains, huge ice fields, thousands of lakes and great rivers, and then drench certain of these areas with as much as twenty feet of precipitation in a year, and you find conditions peculiar to Alaska alone.

The population of Alaska, according to the 1940 census, included some

* Read before the Western Branch, American Public Health Association at the Thirteenth Annual Meeting in Seattle, Wash., May 28, 1942.

† Formerly Assistant Commissioner of Health, Territorial Department of Health, Juneau, Alaska.

72,524 people, 39,000 of whom are white, 32,500 Eskimos, Indians, and Aleuts, and the balance made up of Filipinos, Japanese, and others totaling 900. This census, which was begun in October, 1939, was undoubtedly quite accurate at the time it was completed, but since then conservative estimates indicate an increase of at least 75 per cent in Alaska's total population.

In the best of times, as, for instance, before the war boom, transportation in Alaska was difficult, uncertain, and expensive. The total travel budget for our field personnel of seven persons in the 1942 fiscal year amounted to \$13,300. All methods of travel available are utilized—airplanes, boats, trains, automobiles, but seldom if ever are dog teams used. The airplane has proved a real boon to Alaskans. One can get a plane almost any time to go anywhere, with the conditional "WP"—"PW," which means "Weather Permitting" and "Pilot Willing." I always start a field trip with a great deal of misgiving, as invariably when I am away from Juneau I will spend as much time waiting for boats or for favorable flying weather as I will in actually doing my field work. To pay a winter visit to our nursing service in Nome, some 1,500 miles from Juneau, means an outlay of travel funds alone of \$300, and it may take from 5 days to 4 or 5 weeks to complete the circuit.

Communication is likewise difficult. Letters from some of the reporting villages may take as long as six months to reach the Juneau Office. Radio service is found to be most satisfactory but, even at the half rates available to Territorial agencies, it is extremely costly. Then, too, because messages go not by wire but by radio, they are subject to the strictest military censorship, and often we cannot actually say what we want to say for fear of giving valuable information to the enemy.

The influx of the advance army of

civilian workers on defense projects began in earnest in the fall of 1940 and has continued undiminished up to the present. Exact knowledge on the increase in the population of Alaska is not available, but what we do know is that the continued inflow has made it impossible to plan even from month to month on the needs of established communities, as all plans of Alaskan strategy are military secrets.

One night the people of a community go to bed to wake up in the morning with a transport or two tied up at the docks or anchored in the previously quiet harbor, and the streets and surrounding roads teeming with men of the armed services. Over night a quiet and self-contained little Alaskan town has been transformed into a city—in most instances a rather "rowdy" boom-time city.

All this is happening in many communities, and the townspeople are simply overwhelmed in attempting to supply the diverse needs of these many boys and young men. These towns, all deficient in the ordinary facilities necessary for healthy recreation and entertainment, are unable to provide them. Some progress along these lines is being made, but in practically all cases the descent by these armies of civilians and the military has come so suddenly and unexpectedly that there has been no opportunity for communities to foresee their needs and prepare for their coming.

As long ago as July, 1941, together with officers of the Public Health Service, I made a personal survey of all Navy and Army bases under construction, with a view to obtaining funds under the Community Facilities Bill to provide the necessary sanitary and recreational needs for the adjacent communities. The requirements were almost too numerous to list, but recommendations were submitted immediately to Washington for health centers, hos-

pitals, water supplies, and sewerage systems. This program, however, has been painfully slow in getting under way. Nine months have passed since the survey was made and the first recommendations went in, and we are still waiting for many needed facilities. The fault does not lie wholly with red tape, but is due in part to the reluctance of local communities to accept their share of the responsibility, and to their suspicion of being given so much for so little.

In a few instances, the contractors importing civilian workers to the various defense projects have built their own towns completely. They have erected hospitals, clinics, barracks, mess halls, bath houses, laundries, and have provided some recreation facilities. Some have built temporary small family units for those workers who have brought their wives and children. In a few cases they have built temporary school buildings for these workers' children and for children of the families of the Army and Navy personnel. In these areas no serious public health emergencies have developed, but this type of development has been much too rare.

In the majority of cases the workers and their families have arrived in these small frontier towns and have been forced to shift for themselves in all respects. Shanty towns have grown up on the tundra surrounding the defense projects and nearby towns with all the concomitant health and sanitary problems imaginable. Schools have been overcrowded to such an extent that they have been forced to hold classes in shifts. People have been forced to sleep wherever they could find shelter and to eat in restaurants so overcrowded, and served by people so overworked that they would at times just "close shop" to get some much needed rest.

One experience I had which was not

too uncommon in many other boom towns in Alaska, occurred when forced down in a snowstorm in the interior on a flight from Nome to Anchorage. We landed at dusk on a newly improved field, under construction by the Civil Aeronautics Administration, ours the last of fourteen planes to get in. On inquiry at the better of the two roadhouses, I found that my only chance for a bed was to wait until the 1:00 A.M. shift went to work and then to crawl into the warm bed of some night-shift worker, for a few short hours. They were working on that field in the month of November, three shifts in each 24 hours, and were sleeping three shifts in every cot and bed. At the same roadhouse, incidentally, meals were \$1.50 each—breakfast, dinner, or supper, regardless of taste or appetite.

Immediately following the declaration of a state of unlimited emergency by the President on May 27, 1941, a series of meetings of the Divisional Directors of the Health Department were devoted to planning for probable needs in carrying on the regular program of the department as well as preparing for other exigencies.

Conditions in Alaska being unlike those in any of the States, each town or village is isolated from the others. If the war actually comes to Alaska, many of these towns will be completely isolated as regards outside help, so that plans for civilian defense and emergency services and supplies are based on the precept of self-sufficiency.

Among the subjects considered were those related to obtaining and maintaining large supplies of biologicals and their distribution to various strategically located towns throughout Alaska, plus the institution of a territorial-wide immunization campaign.

Through the Division of Communicable Disease Control adequate supplies of biologicals, including immunization stocks of typhoid fever, smallpox, diph-

theria, and whooping cough vaccines, tetanus and gas gangrene antitoxins, anti-meningococci sera, and drugs for the treatment of syphilis and gonorrhea, were obtained. Emergency depots for the more important of the above materials were established in each town where a Territorial public health nurse was located, so that there was a wide distribution of these materials throughout the whole territory. These stocks have been utilized freely by the civilian physicians as well as by the medical officers in the armed forces. These supplies are being drawn upon constantly and are being constantly replenished.

In February the program for the immunization of all children and adults against certain diseases was intensified. The diseases against which this program was especially directed were typhoid fever, smallpox, diphtheria, and whooping cough. Large stocks of biologicals were placed at the disposal of the private physicians through the public health nurses. The results have been most satisfactory in the protection of an increasing majority of the population. It was necessary to establish a rather liberal fee system for clinics and this has proved, by all ordinary standards, unusually expensive, but nevertheless very worth while.

Ninety per cent of our food must be transported by water from Seattle, as must most of the other necessities of life. With this in mind a food survey was made in December in all the principal towns of Alaska by the National Resources Planning Board in coöperation with the Territorial Department of Health. This was accompanied by an inquiry regarding stocks of drugs, bandages, surgical equipment, and other medical supplies. Response to this survey was slow because of disrupted communication facilities, and it was not until considerably later that an analysis of these stocks and probable future re-

quirements was possible. On the basis of this information, however, requirements in the way of first aid and emergency medical and surgical supplies were estimated. An estimate of the cost of these supplies delivered in Juneau for distribution throughout the Territory was made and the American Red Cross was queried as to its ability to furnish these needs immediately. Promises for furnishing these supplies were forthcoming and some of the materials soon began to arrive. However, as the equipment and supplies provided were neither adequate nor contained the items specifically needed, communities have been forced to improvise. Shortages are still evident in most towns but it is hoped these will be corrected in the near future.

Through the Division of Maternal and Child Health, a pamphlet, "Food Facts," describing ordinary nutritional requirements, was prepared and has been widely distributed. In this pamphlet are listed substitute diets which will provide the elements of good nutrition under emergency conditions. By proclamation from the Office of the Governor of Alaska, residents have been advised to store all food supplies possible, for emergency needs. This is in direct contrast to the policy in the United States proper relative to food hoarding, but as Alaska is so unusually situated it is felt advisable for families to lay in as much food as they can safely store. The department has co-operated with the University of Alaska Extension Service in stimulating Alaskans to plant gardens, and a considerable amount of literature has been distributed by health agencies to future gardeners for this purpose.

Anticipating the many threats to the ordinary routine of a public health department, the policy has been to anticipate probable emergencies in the towns of Alaska which might be caused by enemy action. Sanitary require-

ments in the various areas were analyzed and necessary advisory literature was prepared and distributed to the many exposed communities relative to improvement and safeguarding of water supplies and sewage disposal systems. Other literature was distributed, treating with housing and food and milk sanitation.

The destruction of water supplies is one of the greatest threats, not because of a lack of available water, but because of the possible use of contaminated water. Plans for the patrol and the protection of water systems have been issued to the utility boards of the various cities, and the methods by which units may be supplemented or replaced. Also, detailed instructions have gone out for the proper sterilization of water in case it becomes necessary to use water from a questionable source. Plans for the substituting of pit privies and the maintenance of such have been completed and town officials have been informed of the methods and requirements for this type of public need. Plans have also been completed for emergency housing, not only of the casualties and hospital cases but also of the general civilian population in all the larger towns. Consideration has been given to the public health supervision of the many bomb shelters which are to be used in emergencies, as well as to the community kitchens for feeding large numbers of persons on an emergency basis, and organization for their supervision is being completed.

Early in the fall of 1941 plans for civilian defense organization were instituted. All our public health nurses had complete courses in Red Cross First Aid and many were qualified instructors, as were most of our other professional and technical personnel. All members of the Territorial Department of Health, including the clerical and stenographic staff, volunteered for active participation in defense and emergency medical

organization, and in many instances were the leaders in medical and first aid preparation. Thus, by the end of November, all preliminary preparations were completed in most of the Alaskan communities to respond to almost any emergency.

Each town, at the instigation of the local Red Cross Chapter, organized women's corps of Red Cross workers to be trained in first aid and volunteer nursing services. Groups were organized to prepare first aid equipment, and many of the local schools, through their manual training instructors, and with the assistance of various service organizations, prepared portable first aid kits, stretchers, first aid station signs, air raid shelter signs, etc. Local physicians volunteered their services in manning casualty stations and emergency hospitals and assisted generously in planning the organization of the First Aid and Emergency Medical Service. In each town one physician was appointed as the emergency medical director and was made a member of the committee on civilian defense, thus integrating the first aid and medical work with that of general civilian defense.

From the very first, public health laboratory services have been made available to all the armed forces in Alaska and have been continued, even after the establishment of a large military laboratory. A program was worked out through our laboratories for blood typing all civilians in Alaska. A printed certificate for each individual typed was then issued, indicating that the person was negative to syphilis on that date, and was of a specified blood type. This plan was developed because of the impossibility of establishing adequate blood serum or plasma banks in Alaska, and because of the apparent impossibility of obtaining adequate plasma from the "outside." The typing of civilians eliminates one step

in the procedure of transfusion, if it becomes necessary, in the case of either donor or recipient. The inadvisability of attempting to prepare serum or plasma in Alaska again relates to the expense of the equipment, the small isolated towns and the still smaller hospitals. The largest civilian hospitals in Alaska do not exceed a total bed capacity of 65, and most of them are much smaller. Releases of the Office of Civilian Defense state that it is not feasible to organize the formation of plasma bank centers in hospitals of less than 200 beds.

The blood typing service has also been used on occasion by the Army, Navy and Coast Guard, particularly in Juneau, and at this writing more than 1,000 persons have been typed and serologically tested. As worked out in Alaska, the individual does not necessarily have to present himself to the laboratory to provide the specimen, but may have his blood drawn by a physician anywhere in Alaska, and the specimen is then mailed by the speediest method of transportation to either the Juneau or Anchorage laboratory, where the typing and serology are done. Reports are provided to both the patient and the physician submitting the specimen.

Arrangements have been completed with the Office of Civilian Defense and the American Red Cross, whereby the Department of Health will be responsible for the storage and distribution of blood plasma when and if it becomes available to the Territory. This plasma, of course, will be used only for unusual emergency needs and will be stored at strategic areas throughout the Territory.

Consultative service to the armed forces is available from the Divisions of Communicable Disease Control, Sanitation, and Laboratories. The Division of Public Health Nursing, through its various nurses in the many

communities, has been able to provide ordinary public health nursing services to the families of civilian workers and the armed forces, as well as to carry on all the many special activities which have arisen in the public health nursing field.

Public health educational material in the form of news releases, pamphlets, motion pictures, and radio talks, have been used with the hope of improving public health in general, and have covered all the diversified phases of sanitation, nutrition, home nursing, and emergency services.

One of the most serious problems in Alaska at present is related to three preventable diseases. These are tuberculosis, gonorrhea, and syphilis—of importance in the order named. Tuberculosis, of course, is a problem involving the civilian population largely, while the latter two, which under pre-war circumstances were of comparatively minor significance in Alaska, are, under present conditions, becoming of increasing importance.

The tuberculosis problem in Alaska is as old as the coming of the white man. According to all available statistics, the incidence of tuberculosis in the Territory is greater than in any state or other territory of the United States. The rate of infection is extremely high and the death rate a close companion. It is true that tuberculosis is much more prevalent among the natives than the whites, but accumulating statistics indicate that it is increasing among the white population year by year. A trite but true proverb in Alaska is that the white man first gave tuberculosis to the native and now the reverse process is true. The general death rate from tuberculosis for the year 1941 was 356.0. The death rate among natives for the same year was 701.6, and for the white population 63.9. The likelihood of the spread of tuberculosis to civilian defense workers and the armed

forces by infected residents does not seem too remote, and will certainly occur where intermingling of the enlisted personnel and civilian defense workers with the natives continues as is now the common practice.

One extremely serious and important public health problem which has not been adequately controlled is the increasing incidence of venereal diseases. The companion plague, prostitution, flourishes even more freely under present conditions. This is no new problem in Alaska and, although always of serious consequence, has in the present situation taken on new and dire significance. Alaska has been known as America's "last frontier" and as such has condoned conditions, in many instances quite openly, which would hardly be tolerated in the States. With the coming of this army of workers and fighters to the Territory and with few of the common recreational facilities available, professional prostitution has become a real threat to an all-out war effort.

Control measures consist, in the best regulated areas, only in the registration of the professional prostitutes, and weekly examinations by part-time health officers. They are finger-printed and photographed and if found free of infection are permitted to practise their profession unmolested, except for the weekly check-up. They are permitted to go and come as they choose and, even if found infected, are then only ordered to move out of town without any regular notice or warning to the police or health officials in the next town where they will take up their residence.

The Territorial Department of Health has established detailed plans and procedures by which venereal diseases and professional prostitutes might be more adequately controlled. Reporting of venereal disease cases has been simplified; free laboratory services have been

made readily available; a wide variety of anti-syphilitic drugs are furnished free to physicians for the treatment of any case of syphilis, new or old, indigent or able to pay; and, finally, a fee system has been set up to reimburse physicians for the treatment of medically indigent patients. Drugs for the treatment of gonorrhea are available to physicians on the same basis as for syphilis, and laboratory diagnosis by smear and culture are available to those communities which are readily accessible by plane.

These procedures have not proved adequate for effective control. Much of the fault for the existence of professional prostitution lies in the local communities' *laissez-faire* attitude, but all the blame cannot be credited to the townspeople and officials, for it can be said, with reservations in only one or two instances, that the officers of the armed forces have not viewed with favor a program of repression of prostitution.

With this attitude prevalent, the institution of an organized program for the repression of prostitution has proved not only difficult but, to date, almost out of the question. The small and isolated towns, deficient in ordinary healthful recreational facilities and served by overworked part-time health officers, complacent city officials, and an indifferent public opinion, provide a set of barriers which we have found impossible to surmount. The answer to this problem might be found in a stronger program carried on by personnel from the Territorial Department of Health. This has proved to be not only impracticable but impossible, as the communities are too widely scattered and the central staff too small.

Assistance has been promised by the Public Health Service in the form of trained public health physicians to be assigned to the department to establish and to carry out the necessary measures. The coming year will show some

changes, for venereal diseases are increasing among the civil and military population, and the institution of adequate control measures becomes imperative. When Alaska continues to maintain second place in the gonorrhea rate of all states and territories, as it has for the past year, forceful measures are indicated.

The threat of war to Alaska has seemed very close in the past five months and seems closer with each passing day. We in Alaska feel that eventually we will have to play a more im-

portant part in this war and that it will certainly reach us eventually in the somewhat doubtful future—at any rate that is the basis on which we are making our preparations. It has brought to light many new and unsolved problems. We in the Territorial Department of Health have attempted to foresee the emergencies which will arise when the bombs actually begin to fall. We have planned as carefully as possible for these emergencies and for the most part feel that we are ready to meet them.

The Modern Public Opinion Poll*

A Means of Defining and Appraising Community
Health Education Problems

PAUL D. GUERNSEY, M.S.P.H.

*Assistant Executive Secretary, District of Columbia Tuberculosis Association,
Washington, D. C.*

A BUSINESS man steps out on the street from the entrance of his Park Avenue apartment in New York City. A young man carrying a sheaf of ballots approaches him, saying: "I would like to get your opinions on some public health problems. The Health Department is trying to find out what the public believes about tuberculosis."

"Well—fire away as I walk along. But I'm afraid I don't know much about it."

"What do you think is the cause of tuberculosis?" asks the young man.

A moment's reflection, and then, "Most persons that get tuberculosis have brought it on by not taking care of themselves. They dissipate too much—too much smoking, drinking, and night life—and it just catches up with them."

The young man, jotting down notes on the ballot as he walks along, gives no hint of his own feelings on the validity of this assertion. His task is to get answers, not supply them. He next inquires, "Do you think tuberculosis is contagious?"

"I understand that it is, but I believe it is brought about more by the way an individual lives than anything else."

In the next few minutes the young man has noted the business man's viewpoints on how he believes tuberculosis is spread, the possibilities of curing it, the methods for treatment and diagnosis, and whether he believes it can be inherited. Cordially thanking him for giving his opinions, the young man says goodbye. He stops around the corner, however, to complete the information on the ballot which will properly classify the business man in the cross-section of the public that is being interviewed. Age, sex, economic status, nationality, and location of residence must be noted before the ballot is completed, and to make such classifications the interviewer has had to ask some other questions. These questions were prefaced by the statements, "To be sure that my interviews cover all types of persons living in the city, I would like to get just a little information about you—but I *don't* want your name." Questions would then be asked such as, "Would you mind telling me the general nature of your occupation?" "Were your parents born in this country?" or "Do you live in this neighborhood?"

Visualize hundreds of such interviews being made by capable interviewers, concerning health problems and services, and among all types and classes of persons living in the community. That is the way the public opinion poll technic was used by the District Health Educa-

* Read before the Public Health Education Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

tion Demonstration of the Department of Health in New York City to study some of the educational needs of the 200,000 persons living in the Kips Bay-Yorkville Health District of Manhattan. Also, when Dr. Wilson G. Smillie, professor of Preventive Medicine and Public Health at Cornell University was making a survey of the facilities for the care of the sick in Rochester, N. Y.,¹ he considered it valuable to ascertain the feelings and opinions of the consumers as to the adequacy of their services by means of a poll.

Most large business corporations wishing to influence the public to use their products make a systematic and continuous study of those persons who constitute their market. They find it a sound investment to study the buying habits, living habits, opinions, types of advertisement read, radio programs listened to, and many other matters in the daily lives of all of us. From such an analysis, planning begins as to the best procedure for merchandising and advertising their wares.

The various national, state, and local health organizations have made little effort to adopt such research procedures to study *their* market. Vital statistics, incomplete morbidity statistics, sociological surveys, etc., have been the bases for planning. Valuable as these are, it must be recognized that the effectiveness of any community's preventive or curative health services is, in the last analysis, determined by the personal reactions of its residents toward those services. Therefore, efforts toward adult health education not based upon some accurate knowledge of the thoughts, feelings, and present level of understanding which characterize the cross-section of human beings comprising a community, can be neither completely realistic nor efficient.

Knowledge of the opinions of the man or woman on the street, the clerk in the store, the waitress, the truck

driver, the housewife, the big and little business man, and all the others who make up the typical cross-section of the American community can be very valuable to public administrators and educators. For instance, after carefully interviewing such a cross-section, the New York City Demonstration found that some types of education were ineffective and others of less importance than previously believed.

In certain instances polls reveal substantial reasons for the public's not acting according to the knowledge it may possess. In such circumstances the educator might go on indefinitely trying to achieve a result unattainable by education alone. Illustrative of this point are the results of one of the polls in New York City. The Maternal Hygiene Committee of the Kips Bay-Yorkville Health Center decided to conduct an educational campaign to secure earlier registration for prenatal care. Such a campaign was felt necessary because available records indicated that in this district 50 per cent of the expectant mothers did not register with a clinic or physician until after the 6th month of pregnancy.

When a representative cross-section of the more than 200,000 persons residing in the district was asked about this matter, it was disclosed that over 90 per cent believed that a prenatal examination by a physician was essential, and over 70 per cent believed that prenatal care should be started between the 1st and 3rd month of pregnancy. Obviously, there was little need for the majority of the persons to be convinced that early prenatal care was considered of value. Why, then, the discrepancy between what the people believed and their actions?

For one thing, the poll revealed a distaste for having such prenatal examinations done in hospitals. Since many of the persons in this district, for economic reasons, have to attend hos-

pital clinics rather than consult private physicians, this was a point to be further studied. Why, if they could not afford a private physician, and if they believed that prenatal care was of value, did they not use the clinical facilities in hospitals which were well equipped for giving such care? The answers ran in this vein: "Too many men doctors around." "It is a strain on your nerves and your body to go to a clinic." "Don't like strange doctors pawing me." "You don't get any individual attention—treated like guinea pigs." Other comments showed that hospital administrative procedures, as well as factors in the training of certain private physicians, tended to discourage early registration. In brief, certain aspects of this poll did indicate a need for specific kinds of public education, but the whole problem of securing early pregnancy registration was revealed to have far more implications than could be solved by education.

This situation will serve to illustrate some generalizations which must be taken into account when evaluating the results of a poll.

In an interview a strong negative reaction concerning a situation may or may not indicate wherein the fault may be, since the opinion may be founded upon hearsay or unrealistic expectations as to what a service can or should be. It must be noted, however, that the variety of justifications in the way of comments which people give for their opinions frequently arise from the individual's own experience. These comments are sometimes tinged with emotion, false propaganda, loose reasoning, self interest, or even bitterness but, taken as a whole, they tell a dynamic story. In that story is reflected a stern caution to the educator to remember that personal experience remains the most decisive and permanent form of learning; an object lesson which both administrators and educators, in evolv-

ing their elaborate programs, sometimes forget.

The public opinion poll might be considered the modern counterpart of the "town meeting" because it affords a unique opportunity for democratic expression of opinion in a complex urban community. At the same time, the modern poll, properly conducted, represents an honest search for facts. The results sometimes give little comfort to those unaccustomed or unwilling to face realities.

POLL RESULTS

The following summaries indicate the nature of the material gathered in New York City and Rochester. Interpretation of these results in terms of applying the information to constructive planning cannot be attempted here. In most instances, however, the implications will be obvious.

New York City—

In one poll, while 68 per cent of those interviewed knew the Health Department operated district health centers, almost 80 per cent had no idea what services they furnished. Only a questionable 16 per cent knew the exact location of the health center in their district, since there was reason to believe it was confused with a hospital half a block away.

Eighty per cent believed that our modern way of living had not made it more difficult (physiologically) for women to have children. (The majority think better medical care makes up for any other deficiency.) Eighty-seven per cent thought children should be born in a hospital rather than at home. Of the seven tests or measurements made by a physician in the examination of an expectant mother, 48 per cent of the persons knew two or more.

More than half of those interviewed on one poll did not know that more persons in New York City during 1938

had been killed by falls in their homes than by automobile accidents. A number of persons stated that they had read or heard that more people were killed by falls, but—*they still didn't believe it!* There is a challenge to the ingenuity of the educator!

When asked who they believed was usually at fault in traffic accidents, 37 per cent said pedestrians, 34 per cent said car drivers, and 28 per cent said it depended on the situation. Over half (58 per cent) of those who felt the pedestrians at fault were car drivers, while of those who felt the drivers were at fault, 65 per cent were persons who do not drive cars, *i.e.*, pedestrians.

Only 22 per cent of the persons interviewed said that tuberculosis was caused by a germ, but 68 per cent believed it to be contagious. That climate is the most important treatment for tuberculosis is still believed by 45 per cent. Opinion was almost equally divided as to its being inherited. The contradictions in these figures on the tuberculosis poll (which also occurred in the national poll) are an extremely good indication of the confused thinking of the general public about this disease, in spite of all the education presumably undertaken.

Rochester—

Dr. Smillie in the section of his report on conclusions and recommendations regarding the Rochester, N. Y., study makes the following statement:

The popular opinion study is particularly interesting in that it indicates just how the people themselves feel about the plan for care of the sick that has been developed by the leaders of the community. The people speak in no uncertain terms concerning existing inadequacies, and emphasize what they would like to have done in order to bring about an improvement in the existing situation.

The ballot used in Rochester contained some fifty items dealing with various aspects of care for the sick. The following items are mentioned from

the poll for their general interest value:

One of a series of questions about physicians asked: "How did you pick your doctor?" The replies ranged over a considerable expanse of reasons for selections, but only 5 per cent indicated that their choice of a physician was based on preliminary investigation of his training, hospital staff connections, or such other criteria as are usually recommended. In another question, approximately 5 per cent indicated they seek aid from osteopaths, chiropractors, or Christian Science practitioners.

Rochester pioneered in developing hospital insurance and had under consideration a plan for medical care insurance at the time this poll was undertaken. The public response to questions regarding these insurance plans was therefore quite important.

The first question asked: "Do you believe the average family should have hospital insurance?" Ninety-two per cent said *yes*. The next question was: "Do you believe the average family with children can afford to pay \$1.30 a month for hospital insurance?" Eighty per cent said *yes*. Then they were asked: "Would you like to have a similar insurance plan (to hospital insurance) to aid in paying for medical and surgical care?" On this 72 per cent said *yes*. The probable cost was included in the next question: "Do you think the average family with children would be willing to pay \$3.00 a month, in addition to what they pay for hospital insurance, to cover medical and surgical care?" To this only 22 per cent unqualifiedly said *yes*. Obviously, when the results and comments on these questions on insurance were carefully broken down and analyzed, plans for further promotion could proceed on a vastly more realistic basis.

Partly as a result of the Rochester poll the visiting nurses changed their organization name from Public Health Nursing Association to Visiting Nurse

Association. Only 8 per cent of those interviewed could give the name when asked, "Do you know of any agency in Rochester which furnishes trained nurses at small fees for each visit?" Of those who had used this service, however, the result was 100 per cent enthusiasm. It is to be doubted after this poll that a service so highly regarded by its users will continue much longer to be unknown to the majority of the city's residents.

One question asked: "Is there any medical care which you feel you need but do not have taken care of because of the cost?" Only 15 per cent said *yes*. The comments for this group indicated that almost half referred to surgical attention believed necessary, and a third referred to needed dental care. Practically all the conditions mentioned were chronic disorders which presumably caused some annoyance or discomfort—hence the desire for medical care. Obviously the broader concepts of preventive medicine are apparently remote to the layman. It should be added, for the record, that men and women were represented in equal numbers among those saying *yes* on this item.

Dissatisfaction expressed in certain quarters with the plan used in Rochester to supply medical care for the sick poor was explained in part by the poll. It revealed that over a third of the poor and very poor did not understand clearly the procedure for obtaining a doctor, without cost, for an illness at home.

THE TECHNIC

Simply defined, a public opinion poll is a method of determining public reaction by interviewing a scientifically selected cross-section of the population. It should not be confused with "straw votes" taken of such population groups as telephone subscribers or automobile owners, in which the emphasis is on amassing a large number of returns. "Straw votes," regardless of the quan-

tity, are not representative of all the heterogeneous opinion groups (e.g., young people vs. older people, wealthy vs. poor, etc.) in the total population.

In the public opinion poll, the number of persons interviewed is not nearly so important as is the accuracy and representativeness of the cross-section of the population which is to be interviewed. Once the cross-section of any unit of the population (e.g., a city, county, or state) has been accurately determined, a relatively small number of interviews, if they adhere strictly to that cross-section, will produce a fairly true picture of how the population is thinking about any given problem *at that time*. The classifications or controls which are used in determining a cross-section of the population will vary according to the purpose of the sampling procedure and the nature of the population to be considered. The main point is that interviews should be obtained from each of the opinion groups which make up the total population of a community and *in exact proportion to the size of that group in terms of the total population*.

In the polls conducted in New York City and Rochester, N. Y., the cross-section to be sampled contained five statistical controls: age, sex, nationality, economic status, and geographic distribution of the population. Each one hundred interviews tabulated had to be apportioned perfectly to these five controls. A spot map made of each hundred interviews showed geographical distribution in conformity with population densities, as well as a general spread. In each hundred there had to be the correct percentage of persons of above average, average, and below average income; of persons between 18 and 44 years of age and over 45; of men and women; and of foreign white and native white stock.

In conclusion it is pointed out that the modern public opinion poll, properly

conducted, is a scientific statistical procedure. To be of value it must be done carefully, by a person well trained in the technic, and conducted as an honest search for facts. With a staff member of a health organization properly trained in this procedure the cost of conducting opinion polls is not prohibitive, and may well be considered a sound invest-

ment in providing materials for efficient, intelligent planning of future work, not only in education but in public health administration.

Effect of Hibernation on Content of Coliform Bacteria in Oysters

JAMES GIBBARD, F.A.P.H.A., AND ALEX G. CAMPBELL

Department of Pensions and National Health, Ottawa, Canada

AND

A. W. H. NEEDLER AND J. C. MEDCOF

Fisheries Research Board of Canada, Ottawa, Canada

DURING the autumn and winter of 1940 and 1941, the Department of Pensions and National Health and the Fisheries Research Board of Canada undertook an investigation of the effects of hibernation on the coliform bacterial content of oysters at Buctouche, N. B. It was thought possible that the contamination of oysters grown in some areas too polluted to permit direct marketing at other seasons might be sufficiently reduced during the winter hibernation period to make them safe food products. If hibernation was found to be a factor of safety, closure of such polluted areas and a consequent serious economic hardship to fishermen might be avoided.

It has long been known that feeding activity ceases in our Atlantic oysters (*Ostrea virginica*) at a temperature of about 5° C., apparently because the coördination of ciliary activity breaks down (Galtsoff, 1928). At temperatures close to 0° C. oysters remain closed almost continuously and are so inactive that, although they do not feed at all for long periods, the glycogen content is not appreciably reduced. It has also been shown that in sewage-polluted waters there is a decrease in the coliform bacterial content of oysters associated with this hibernation (Hunter and Harrison, 1928). According to

Fisher and Acker (1935) the coliform content of water is less in winter than in late fall; "a marked improvement in the quality of oysters occurs within 1° C. of the freezing point" and "this improvement was much more consistent at these lower ranges of temperature than at any other cold-weather ranges."

In 1925 the U. S. Public Health Service Committee on Sanitary Control of the Shellfish Industry recognized hibernation as a factor of safety and stated that it might be utilized when the water temperatures fell to 5° C. or lower. This principle did not, however, receive general application in the United States.

In Canadian Atlantic oyster areas the water temperatures remain continuously below 0° C. for a considerable period each winter, during most of which the inlets are covered by ice. The conditions for the use of hibernation as a factor of safety are, therefore, much better than in warmer countries. Temperatures approaching the threshold of feeding activity (5° C.), and in our opinion too close to it for safety, were included in the hibernation period as tentatively applied in the United States. This was probably responsible for the apparent unreliability of the principle and, consequently, for its rejection there. Because of longer periods of

Phase of Tide at Time of Sampling:

cold water in Canadian Atlantic oyster areas, it is unnecessary to include such temperatures, or, indeed, any above 0°C. , in the period during which hibernation may be considered as a factor of safety.

LOCALE

Buctouche, N. B., harbor was selected for this study because it is one of our more important natural oyster producing areas and had been shown on previous surveys to be subject to a fairly high degree of pollution. Oyster beds close to the village were considered potentially dangerous, but complete prohibition of fishing on them would cause serious economic hardship to local fishermen. An investigation of the coliform content of hibernating oysters had, therefore, an immediate practical significance in this locality.

The topography of the area is indicated in Figures 1 and 2. Although the population of the village is only about 1,000 and sewage from only a small proportion of the population flows directly into the estuary, surface drainage from higher levels through the

village is also important. The impervious nature of the soil aids rather than prevents pollution from reaching the river. A number of dwellings of a poor sort close to the water at the up-river end of the village and boats at the wharf add to the pollution. As a result the areas close to the village must be considered too dangerously polluted to permit the direct marketing of oysters during open water. This is shown by the bacteriological data given below (Table 1).

METHODS

Bacteriological examinations of oysters and of overlying waters, and the recording of meteorological and hydrographic data, were commenced at the middle of September and continued until December 9 when the ice had formed for the winter. The investigation was resumed for a short period in January in order to determine conditions after water temperatures had been below 0°C. for a considerable period.

Samples of oysters and of the overlying water (approximately 1 ft. off the bottom) were taken 3 times a week

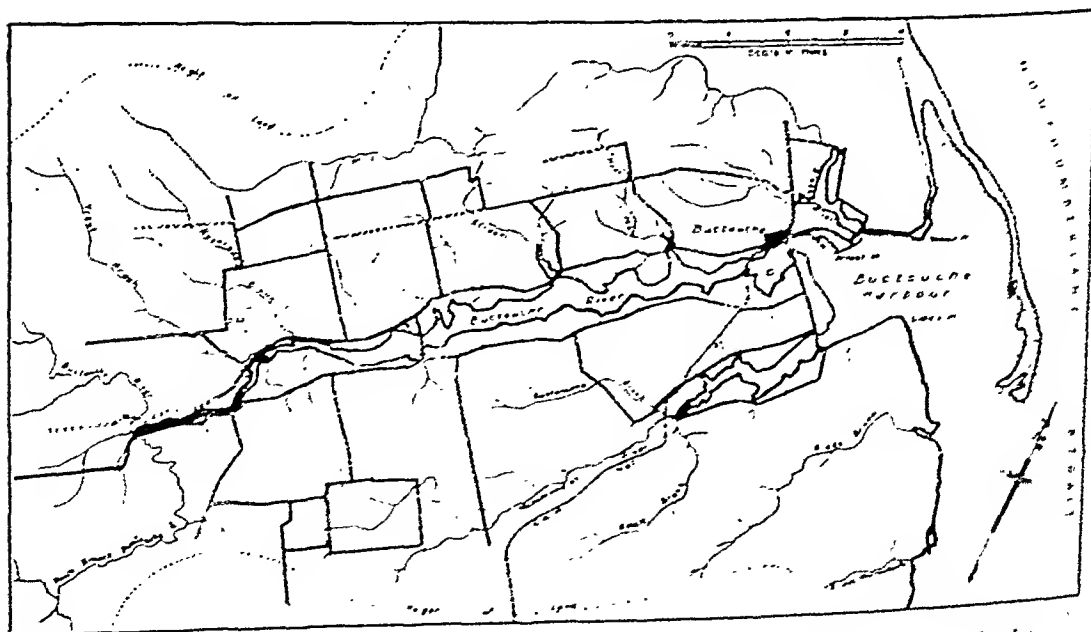

FIGURE 1—Chart showing topographical features of the Buctouche, N. B., district

FIGURE 2—Chart showing the positions of the four sampling stations and the hydrographic station (H), in relation to the village of Buctouche (hatched).

at the 4 stations indicated in Figure 2. The positions of the stations in relation to the source of pollution have a direct bearing upon the results. Station 1 was farthest from the source of pollution, station 2 nearer but still at a distance, station 3 opposite the outlet of a cesspool, and station 4 just upstream from the outlets of several smaller sewers. At stations 1 and 3 the depths were 6 to 10 ft., and at 2 and 4, 15 to 25 ft. The hydrographic station was at the wharf where the water was 30 ft. deep. Water temperature readings and salinity samples were taken at three levels—surface, 8 ft. and 20 ft.—at the time of sampling. At the same time the phase of the tide was recorded.

The bacteriological methods employed were those outlined in the *Tentative Standard Procedure for the Bacteriological Examination of Shellfish and Shellfish Waters* of the American Public

Health Association, December, 1940. All the bacteriological work was performed in the mobile laboratory of the Department of Pensions and National Health. Samples collected during the morning of each day were placed on test during the afternoon. During the winter the oyster samples were taken to the laboratory in pails containing water from the bay to prevent them from freezing. Three tubes were inoculated with each of three dilutions, and probable numbers of coliform organisms per 100 ml. were calculated.

RESULTS

Table 1 summarizes the data collected and Figure 3 illustrates the relationship of oyster pollution to water temperature and water pollution at station 2.

Effect of weather on the coliform content of the water—The data show

that great variations occurred in the coliform content of the water, and indicate that weather is an important factor. It may be seen that high values, such as occurred on September 20 and 27, October 11, and November 15, were preceded by heavy rain and wind. Rain, by increasing surface drainage, increases the volume of pollution entering the inlet. This in turn is reflected in a reduction of surface salinities. Heavy winds tend to keep pollution in suspension, but once the

bay is protected by ice, the stirring by winds is prevented.

The investigation did not clearly reveal the influence of other factors on pollution of the water until the onset of cold weather. Much surface drainage was then eliminated by freezing and one of the major sources of pollution thus removed. The data in the table show that the coliform content of the water fell to a comparatively low and constant level at about the same time as ice was formed on the inlet. The

FIGURE 3—Showing water temperatures at the hydrographic station and most probable numbers of coliform organisms (M.P.N.'s) per 100 ml. of water and oyster meats at station 2

latter occurred on November 26 and would approximate the time when surface drainage was measurably reduced by frost.

Correlation of coliform content of water and of oysters during warm weather—The variations in the coliform content of the oysters were roughly parallel to those of the water up to October 21 when the water first became too cold for active feeding. This indicates that the coliform content of the oysters is both increased and decreased rapidly under such conditions and, therefore, quickly influenced by that of the water.

Influence of low temperatures—hibernation—After October 21 the temperature of the water rather than its coliform content became the controlling factor in the pollution of the oysters. On that date it fell from about 9° to 4° C. as a result of a heavy snow storm. The coliform content of the oysters suddenly disappeared for a considerable period in spite of the fact that the water remained polluted. Water temperatures again rose to 6° C. on November 13 and the oysters again became polluted. After this date the temperatures fell away again but this time very gradually. The accompanying decrease in the contamination of the oysters was likewise very gradual but it had disappeared, except at station 3, by the end of the month. The suddenness of the temperature decline may be of importance in regulating the speed of the self-purification of the oysters.

Importance of very low temperatures—Although water pollution persisted throughout the investigation, the table shows that no coliform bacteria could be demonstrated in the oysters after the temperature had fallen below 0° C. for a few days. This applies even to

station 3 where the oysters were subject to the worst pollution. Extensive hydrographic data on a similar inlet show that after the ice has formed the temperatures remain below 0° C. for the rest of the winter (Needler, 1941). There is, therefore, reason to believe that mid-winter conditions are stable and that the observations made in January are representative.

The data clearly indicate the absence of coliform bacteria from oysters when the temperatures are below 0° C. This is contrasted with a variable, though usually low, content when the temperatures are below but near the threshold for feeding activity, 5° C. This confirms the findings of Fisher and Acker (1935) cited above. In Canadian waters, where sub-zero temperatures occur in all oyster producing inlets for about 3 months or more, hibernation can contribute to the safe utilization of oysters to a greater degree than in waters where such low temperatures do not prevail for any considerable period. Although some areas are so grossly polluted that oysters could not be used safely at any time, others which are dangerously polluted in warmer weather can be considered safe when covered by ice.

Time required for hibernation to become effective—The data indicate that when the water temperature first fell below 0° C. there was a quick effect on the coliform content of the oysters. On the other hand, it was still demonstrable in oysters at station 3 for at least 2 days after the temperature fell below 0° C. Thus, the coliform content does not disappear immediately after such temperatures are reached. For greatest safety it seems wise to obtain the full effects of the sub-zero temperatures by postponing commencement of the winter fishing until at least 2 weeks after final formation of the ice.

† Does not total 100 per cent, since some of the children harbored more than one strain.

presence of those higher strains that are encountered infrequently is especially significant, and therefore have omitted them from the table.

There is one outstanding feature of Table 1: the high prevalence of Type 14 pneumococcus in the throats of the children on the medical wards. We know that Type 14 pneumococcus is the most frequent and most serious cause of pneumonia in babies. This strain is encountered infrequently in a normal population, and when it is found in the throat of a small child, one must consider it a danger signal.²

The relative prevalence of various types of pneumococci that are encountered in the throats of infants and children has been determined by various workers. Nemir and associates,³ for example, have presented the data given in the first column of Table 2. We have compared the prevalence of the various common types of pneumococci encountered in our series (shown in column 2) with Nemir's data. The percentages show clearly that the only outstanding feature of our series is the high prevalence of Type 14 pneumococcus. Our own previous studies of pneumococcus incidence in normal per-

sons living at home,¹ which included both adults and children, indicate that the normal prevalence of Type 14 pneumococcus in the control families is approximately 3 per cent. This is comparable to Nemir's data.

Thus, in the present studies, Type 14 pneumococcus showed a prevalence of nearly ten times the normal expectancy. In fact, the prevalence of this type in the present study compares very closely with the relative prevalence of Type 14 in previous studies of series of actual cases of pneumonia that have occurred in children under 2 years of age. Curren,² for example, in a study of a series of 600 pneumonia patients between 2 and 12 years of age, found that 25 per cent of the children with pneumonia were infected with Type 14 pneumococcus.

This analysis of the preliminary data makes it quite evident that it is necessary for us to explain the source of Type 14 pneumococcus in the ward, and to determine the cause of its presence there.

A study of the clinical condition of the children who were admitted to the medical ward gave us some inkling as to the reason for the high prevalence of Type 14 pneumococcus. Long and his coworkers,⁴ in their studies of the nasopharyngeal flora of infants at the Boston Infants' Hospital, noted that Type 14 pneumococcus was prevalent not only in cases of pneumonia, but was encountered also frequently in infants with upper respiratory infections. They state that Type 14 was not found in the throats of normal babies. In our

TABLE 2

Prevalence of Pneumococcus Types Commonly Encountered in Infants and Children

3	6.6	9.1
14	4.7	32.4

series, 114 of the 154 patients studied had some form of acute respiratory infection during their stay in the medical wards. It seemed quite possible that the Type 14 pneumococcus was prevalent because it was associated with acute respiratory infections other than pneumonia. An analysis of the incidence of Type 14 pneumococcus in acute respiratory illness is given in Table 3.

TABLE 3

Prevalence of Type 14 Pneumococcus in Children with Respiratory Disease on the Medical Wards

Those with Other Acute Respiratory Illness	83	30
Controls		
Children with No Respiratory Illness	40	10
Nurses Caring for the Children on the Wards	62	6

Table 3 shows that in one-third of the children with pneumonia, Type 14 was the presumable cause of the infection. The incidence of Type 14 pneumococcus in the children with other respiratory infections was equally high. At first, this seemed very important and significant, until we observed that one-fourth of the normal children also carried a Type 14.

In addition to the cultures taken on the children, we also obtained a series of cultures from nurses and physicians who cared for the children on the medical wards. Most of the nurses were on an affiliation basis: thus, they worked on the wards of the hospital for a few weeks only. This resulted in a constant change in the nursing personnel, so that it was not possible to follow the nurses with serial throat cultures for any length of time. From the total of 62 nurses cultured, 6 were found to be carrying Type 14 pneumococcus. In no instance was the infection in the nurse

associated with pneumonia, or even with mild respiratory infection.

It is quite clear from Table 3 that there is no statistically significant difference in the prevalence of Type 14 pneumococcus in individuals who did or who did not have respiratory disease. This was a most baffling situation. One explanation might be that Type 14 was a relatively innocuous strain of pneumococcus that had simply seeded itself down in a group of children without causing any particular trouble. It was found in the throats of children with pneumonia and other respiratory diseases simply as a more or less harmless concomitant, and bore little or no relationship to the infective process. We did not believe this hypothesis to be the correct one, but we had no proof to the contrary.

During the course of our investigation in the hospital ward, we had noted that a considerable number of children with respiratory infections were being admitted to the ward from a common source—Nursery 6. This nursery, situated in a distant wing of the institution, was planned to care for normal babies that were awaiting placement in foster homes. Whenever a child in the nursery became ill, he was transferred to the hospital.

When we began our work on the medical ward, we found 6 children on the ward who had been admitted from Nursery 6 from one week to one month previous to the beginning of our study. Each of these children gave a history of acute respiratory infection, followed by otitis media. One had had severe conjunctivitis and 3 had had pneumonia. Each of these children was practically recovered from his acute illness when we began our work; nevertheless, 4 of the 6 had Type 14 pneumococcus in the throat at the time we made our first series of cultures. As our work progressed, we noted that children were being admitted to the medical ward in

increasing numbers from Nursery 6, all with respiratory infections. Five children, for example, were admitted from Nursery 6 with otitis media. The illness began with an acute respiratory infection, which was soon complicated by more serious and extensive symptoms. In each of these 5 children, Type 14 pneumococcus was obtained from the discharging ears or from the throat. We noted also that all these children had resided in the nursery for more than 20 days prior to the onset of illness.

Six other babies were admitted from Nursery 6 to the medical ward with pneumonia, and in 5 of them the pneumonia was associated with a Type 14 pneumococcus. This high prevalence of Type 14 pneumococcus in the children who were transferred from Nursery 6 to the medical wards indicated that it would be wise to look to the nursery as a possible source of invasion of the medical wards with Type 14 pneumococcus.

STUDIES IN NURSERY 6

We first appreciated the importance of Nursery 6 as a focus of infection with Type 14 pneumococcus about the first week of March. It became increasingly clear that here, in this nursery, was an important source of infection with this strain; and therefore we began to study the prevalence of Type 14 pneumococcus among the normal children in the nursery on March 11, and continued observations in this nursery through July 29.

This nursery covered an entire floor in another wing, and was composed of 8 rooms with from 2 to 12 beds in each room, a total of 63 beds. These beds were not separated by partitions; otherwise the medical and nursing care was essentially the same as on the medical floor. The children were cared for by student nurses who were on an affiliation basis, and who came and went in

much the same manner as we have already described on the medical ward.

The population of the nursery was changing continually. Well children were brought into the nursery and kept there until they could be boarded out in foster homes or returned to their parents. New children who were admitted remained only so long as was absolutely necessary to arrange for foster care. Whenever a child became ill, he was, of course, transferred to the medical ward. The ages of the children in the nursery ranged between 3 months and 9 years: 60 per cent were less than 2 years of age, and 30 per cent from 2 to 5 years of age. There was a good deal of shifting about of the children in the nursery. One child did not stay in the same bed or the same room for any length of time. This continuous movement of the children made it impossible to determine each individual's contacts. It did aid our study, in that it gave ample opportunity for frequent transfer of existing infection from one child to another, as later evidence clearly indicated.

During the entire period of study in the nursery, 150 children were enrolled. The throats of all were cultured within a week after admission, and serial cultures were repeated on each child at least every fortnight. Four hundred and thirty-one throat cultures were made on these children, of which 81.5 per cent were positive for pneumococci. All told, 493 strains of pneumococci were found. The number is accounted for, of course, because in some instances a child harbored more than one type. The distribution of the pneumococci among the 150 children in the nursery is given in Chart 1. Practically all the higher types were found, but were present in such a small proportion of the cases that we did not consider it of sufficient interest and importance to include them in this chart.

Chart 1 indicates quite clearly that

CHART 1

PREVALENCE OF PNEUMOCOCCUS TYPES
AMONG CHILDREN IN NURSERY SIX

COMPARED WITH NEMIR'S SERIES OF NORMAL CHILDREN

the prevalence and the distribution of the various types of pneumococci in the nursery was similar to the distribution that we encountered in the medical ward. Type 14 was by far the most prevalent strain; other types of pneumococci were encountered in approximately normal proportions and in the same order of distribution as encountered in the medical ward.

The most striking thing about our studies in the nursery was that nearly half the children—45 per cent—carried a Type 14 pneumococcus at one time or another. These results are very different from the findings of other authors, and also from our own previous studies, all of which have indicated that Type 14 is *rarely* encountered in the throats of normal children. This point is most significant. It is generally recognized, as we have previously stated, that Type 14 pneumococcus is the most important factor in the production of pneumonia in children. High prevalence

of this strain should be a matter of serious import.

Yet we had ample evidence that a virulent Type 14 pneumococcus had invaded a community of normal children without producing any symptoms. But it might be of potential danger. It is possible to imagine that some other factor might then enter this community, which is infected with a virulent but dormant strain of pneumococcus, and act as a fuse which would set off an explosion of serious respiratory disease. Normal children might harbor the virulent Type 14 pneumococcus for some time without ill effect, but some other factor might lower the resistance, general or local, of the child harboring this strain to such a degree that the virulent pneumococcus, which is resting unobtrusively in the throat, would flare up suddenly and produce serious symptoms.

We believe this hypothesis to be correct. It seems probable that the factor which was responsible for lowering the

resistance of the children to pneumococcus invasion was an acute upper respiratory (probably virus) infection. This initial infection, though in itself relatively mild in nature, enabled the virulent Type 14 pneumococcus to establish itself solidly and produce a train of serious symptoms.

During the period of our observation in the nursery, some 20 per cent of the children developed upper respiratory infections. Some of these had simple nasopharyngitis of the usual short duration, but other children developed otitis media or bronchitis, and a few had pneumonia.

We have prepared two charts, one of 15 children who developed acute colds while in the nursery, and another of 15 children who remained quite normal and free from respiratory infection throughout the investigation. Serial throat cultures were taken on these two groups.

Chart 2 gives chronologically the results of the serial bacteriological studies of the children who had respiratory in-

fections. The duration of the respiratory infection is indicated by the brackets. Each culture in which Type 14 pneumococcus was found during the acute respiratory infection is indicated by a black circle. Cultures from normal children are indicated by squares. The chart brings out the very interesting fact that many of the children were harboring Type 14 pneumococcus *before they developed an acute respiratory infection*.

Case 5 is a good example. This child had a Type 14 pneumococcus in the throat a week after admission to the nursery, but showed no symptoms until March 26. On that date an acute upper respiratory infection developed, and on April 2 cultures taken from the throat, the middle ear discharge, and also from the discharge from the severe conjunctivitis, all were positive for Type 14 pneumococcus.

In case 6, cultures were taken from the child within 4 days after admission, and she was found to be already harboring

CHART 2

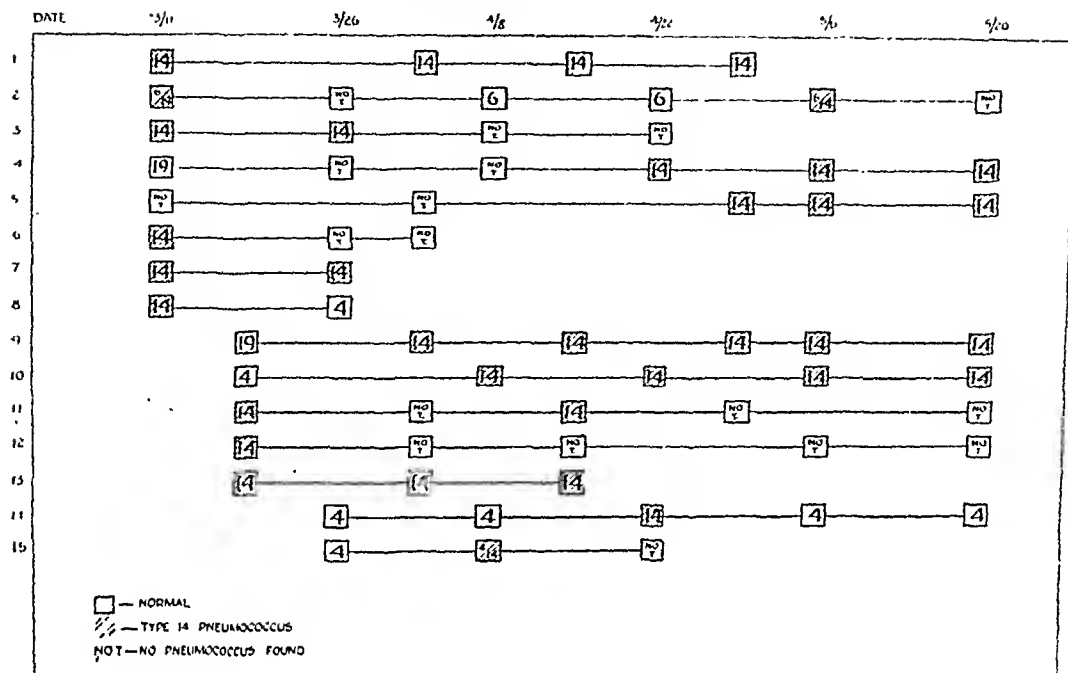

CHART 3

CONTROL SERIES OF CULTURES FROM 15 CHILDREN
IN NURSERY G
WHO HAD NO COLDS.

a Type 14 pneumococcus. Acute respiratory symptoms began on April 3, and on April 8 pneumonia developed. The sputum showed large numbers of Type 14 pneumococci. The child returned to normal about April 18, but cultures from the throat taken on the 22nd still showed Type 14 pneumococcus.

These observations on the two cases that we have described are quite typical of the results obtained in all the children whose serial cultures are illustrated in Chart 2. Type 14 pneumococcus did not seem to initiate a respiratory infection, but if a respiratory infection occurred in the presence of this organism, the strain found a fertile soil for invasion of and multiplication in the deep tissues.

Chart 3 illustrates the results of serial throat cultures upon 15 normal children who spent some time in the nursery. They acquired Type 14 pneumococcus, usually within one or two weeks after

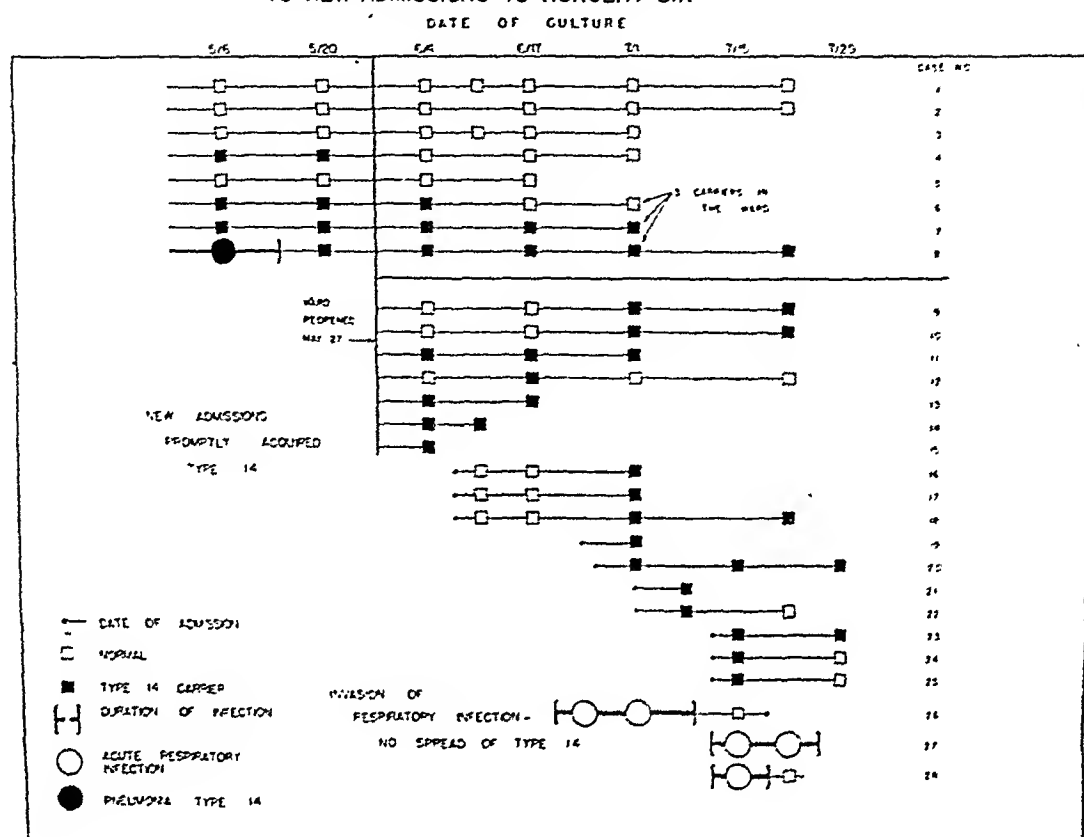

admission, and carried the virulent strain, often for many weeks, without apparent ill effect. None of this group developed an acute respiratory infection. The Type 14 pneumococcus caused these children no apparent harm.

These two charts show that the prevalence of Type 14 pneumococcus was almost exactly the same in the well children as in the group of children who suffered from respiratory disease. Thus, it may be argued that the Type 14 pneumococcus was a harmless concomitant invader, and played no part in the respiratory infections of the group.

We do not believe that this is true, since, in the children who were ill, Type 14 was found in very large numbers, often in pure culture, in the purulent secretions from the ears, the conjunctivæ, the bronchi, and the lungs. Type 14 was present frequently in normal children, but often it occurred in such small numbers that it was difficult to find.

CHART 4

SPREAD OF TYPE 14 PNEUMOCOCCUS
TO NEW ADMISSIONS TO NURSERY SIX

TRANSMISSION OF TYPE 14 PNEUMO-
COCCUS IN A CLOSED COMMUNITY

In the late spring we had an excellent opportunity to study the invasiveness of Type 14 pneumococcus under epidemiological conditions that resemble closely the classical controlled laboratory experiments in epidemiology of Greenwood, Topley, and Wilson.

Nursery 6 was closed to new admissions on April 25 because of an outbreak of chicken pox. Nine children remained in the nursery: all had been carriers of Type 14 pneumococcus at some time during the winter, and one had had pneumonia. Gradually, the Type 14 pneumococci disappeared, so that on May 21, when the nursery was reopened to new admissions, there were only 3 Type 14 carriers in the group.

We obtained serial cultures on each new admission to the nursery during

June and July, and maintained serial cultures on the original group. The results of this study are shown in Chart 4. The chart shows that every newly admitted child acquired Type 14 pneumococcus within a month after admission. Some picked up the infection at once. In others, the infection did not occur for 2 or 3 weeks. The children from the original group who had harbored Type 14 during the winter and had lost it did not pick it up again.

Three children were admitted to the nursery during June and July with acute respiratory infections. This illness did not spread to the occupants of the nursery who were harboring Type 14 pneumococcus, nor did the children with the acute respiratory infection acquire the virulent Type 14 pneumococcus. One may conjecture that the season of the year was the important

factor in prevention of the spread of respiratory illness in the nursery at this time. If respiratory infection had been introduced into this situation in the fall or winter, we believe that the results might have been different.

SUMMARY

Type 14 pneumococcus invaded a group of normal children in Nursery 6 of the institution, probably in the early fall of 1939. This virulent strain, which is generally recognized as the most important cause of pneumonia in babies, caused no apparent harm to its host unless the individual developed an acute respiratory infection. When this occurred, the dormant pneumococcus at once invaded the tissues of the throat, and in some instances spread to the middle ears, the conjunctivae, bronchi, and the lungs.

Children from Nursery 6 who became ill were sent to the hospital ward. They brought Type 14 pneumococci with them. The strain spread throughout the medical ward, infecting most of the children on the ward at one time or another. If a child who had Type 14 pneumococcus in his throat developed a respiratory infection, the results were frequently quite serious.

This is the first instance in which we have encountered a high prevalence of a virulent pneumococcus strain in a community *in advance of the onset of illness in those who were carrying the strain.*

The studies suggest that a virulent strain of pneumococcus may enter a community, permeate it, invade many individuals, and linger for a considerable time without causing any apparent harm. Some untoward factor may then enter the picture (such as an acute respiratory infection) which will lower the resistance of the carrier of the virulent pneumococcus strain to such a degree that the strain will invade the tissues of the body and produce a serious illness.

Deputy State Health Officer, Hagerstown, Md.

WORCESTER COUNTY, Md., is typical of the Eastern Shore area of that state, conservative and provincial, but favored with diversified crops and ample food resources. There is no reason why there should be a nutrition problem except that many of the 14,000 white and 7,000 colored inhabitants are poor and ignorant, and have large families. The possibility of fruitful nutrition work, other than in infant feeding, was scarcely considered by the health department personnel until the state nutritionists enabled them to visualize the existing problem and to learn some of the practicable technics for nutrition teaching and promotion.

A school lunch program was believed to be the most dramatic and tangible way to start work for better nutrition. However, it was decided to include educational work with prenatal patients and with family units. It was also decided to provide certain food supplements, if possible.

SCHOOL LUNCH PROGRAM

In examining the school lunch program as it then existed in the county, it was noted that only 7 of the 23 schools had any type of lunch program, and in only 2 of these was it customary to provide free lunches for children from indigent families. The lunch program varied

from a single hot dish and sandwiches to a modern cafeteria service. Thus it was apparent that much room for work existed in schools; but evidence was needed of an existing nutritional problem in order to "sell" the community.

Dietary Survey—One of the earlier efforts was to define the magnitude of the nutritional problem among school children by means of a dietary survey. The data were recorded on a mimeographed sheet, listing a detailed inventory of the child's food consumption the previous day. A factor of error was granted, and a seasonal influence, but the nurses were sufficiently impressed by the results of the survey to consider the picture it revealed as essentially correct.

The findings more than confirmed the impression of poor dietary habits and the existence of a nutritional problem. For example, on the day of the survey during the winter, only 41 per cent of the children had two or more cups of milk; only 19 per cent had a diet adequate for vegetables other than potato; only 20 per cent had an adequate diet for fruits; 41 per cent for cereal or whole grain; but 97 per cent for meat. The others had either inadequate amounts or none at all of these various types of food. It was of further interest to learn that only 7.6 per cent of the children had a diet adequate in all five factors studied; 23 per cent were totally deficient in one factor; 35 per cent in two; 27 per cent in three, and 7.5 per cent in four. It was believed that such results with 1,169 school children must be significant.

* Read at a Joint Session of the American School Health Association and the Health Officers, Food and Nutrition, Maternal and Child Health, and the Public Health Nursing Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

To secure the basic data the coöperation of parents was enlisted in interviewing the younger children, grades 1-6. Above this grade the children filled out the forms as a classroom exercise. A nurse demonstrated the technic of an interview and supervised the work. The women who helped, and many of them were used, were impressed by the dietary picture revealed. For some the experience was emotionally moving, and lost none of its power as it traveled around the county at bridge clubs, church guild meetings, etc. The findings themselves and the propaganda created by the interviewers did more than anything else to marshall effective support for a school lunch program.

Other familiar promotional technics were utilized, such as programs at public meetings, newspaper articles, and exhibits.

The health department assisted in translating the community interest and support into action; however, it was left to the schools to assume the responsibility for the school lunch programs.

Supplies, Equipment, and Personnel—The question of supplies and equipment for schools just starting lunch programs was the least of the problems. These were made available by the school boards and by contributions of community organizations and individuals. It was believed that contributions by the local public health association, particularly if they could be made on a matching basis, would help and stimulate those schools with the poorest local resources. During the first year \$100 was set aside for this purpose. For the future, it was planned that the public health association would be employed as a purchasing agency, particularly for small schools operating on a financial shoestring, and thus enable them to save money by buying in quantity.

The use of surplus commodities proved a powerful weapon in making possible a school lunch program, but it took about a year to work out a satisfactory modification of the regulations governing the distribution of these commodities. At the time our work began it was permissible to use them only in free lunches. The school was obligated to purchase identical supplies for use in paid lunches. Since the commodities were seldom sufficiently varied to permit the preparation of an entire lunch, it was, of course, necessary to supplement the surplus commodities for free lunches with other foods at the expense of the schools. Under these conditions the use of surplus commodities was not particularly helpful. Finally, the regulations were so modified that the commodities could be used for all lunches, free and pay, with the school providing supplementary foods for free lunches of a value at least equal to the surplus commodities accepted. When this was done, surplus commodities were acceptable to the school board and proved most useful in encouraging the lunch program.

Several resources were tapped for labor. Some of the larger schools secured cafeteria managers and workers through the WPA, but it was difficult to find persons who could qualify for the WPA and who at the same time were acceptable for this work. Smaller schools received help through the NYA. Other schools used volunteer workers, teachers, pupils, and parents for voluntary or part voluntary services.

Certain sidelights are interesting. Especially in a year of poor prices, but also at other times, it is possible to obtain products free for the picking. It was only necessary to organize volunteer labor for the picking and facilities for canning. The parents of pupils in one school for colored children conducted a summer canning project, using products obtained in this way. Some

canneries will put up food at little cost if it is first prepared. Another colored school maintained a program for a year, depending largely on supplies carried by the children and donated from home. Through the public health association a county-wide solicitation of canned goods and staple vegetables was approved, but lack of promotional time made it impossible to inaugurate the drive. There is no doubt, however, that much food could have been secured in this way.

Special Problems—Little effort was made to combat the concession problem—i.e., the sale of candy and soda water at lunch time in the school, but the need for doing so was recognized as an early "must." Obviously, many children spent their money for these items instead of buying a nutritious lunch. The profits from these concessions often went to support school projects, such as purchase of athletic or auditorium equipment or library books. As such, the concession really represented a vested interest, and to combat it required tact and salesmanship. It was essential to sell schools on the idea, first, that profits from the lunch room should go back into the lunch program and that other projects must be financed in other ways; second, that if the lunch program really succeeded, there should be very little candy and soda water sold, and hence little if any profit from this source. A step in this direction made by some schools was the limiting of candy sales to a very short time near the end of the lunch hour.

Menus were poorly planned in some instances. This was particularly true in smaller schools with no home economics teachers and with such limited facilities that only a dish or two at most could be offered. For example, one school frequently limited its lunch to "hot dogs." Some teachers needed supervision in the wise and economical

purchase of foods. For example, one school purchased fresh milk for cocoa when evaporated milk would have been cheaper and more convenient to handle.

It was also noted that certain types of surplus commodities were useless. Flour was one example if facilities for cooking, baking, or proper storage were not available. In other cases the teachers or cafeteria directors needed to learn how to use unfamiliar kinds of commodities.

Much of the food served free to children from indigent families was not eaten by children who were accustomed only to "hog meat" and potatoes. This represented waste, defeated the object of the free lunches, and had an unfavorable effect on the community. Supporters of the program tended to become discouraged when faced with such incidents. To combat this, the skillful teacher would discuss new and unusual dishes to be served for lunch in the classroom before the noon hour, explaining the value of such dishes. Efforts were made to establish a favorable group spirit among the pupils toward the school lunch—a technic that was often successful.

A further problem was the child who brought an unbalanced lunch from home. A home visit by the nurse or a PTA member might remedy this situation.

There was always the problem "who is eligible for a free lunch?" An eligibility committee, consisting of teachers, PTA members, nurses, and welfare workers worked out well.

It is our belief that most problems can be solved within the school by the teachers and pupils if they become sufficiently interested. Toward this end certain procedures were considered; such as school cafeteria committees, conducting institutes, and a periodic bulletin for teachers and cafeteria workers with nutrition news, teaching technics, and suggested menus. These

devices and patient personal contact work in time can solve most local problems.

THE PRENATAL PATIENT AND THE FAMILY UNIT

In addition to working on the school lunch program, other group activities in promoting nutrition were utilized. For example, the county home demonstration agent upon request visited the prenatal clinics, discussed nutrition with the patients, and demonstrated an appropriate dish. A home economics class for underprivileged women was conducted in one of the high school buildings, but for lack of attendance did not succeed.

In addition to these group activities, serious efforts were made to work with prenatal patients and with family units. For information on which to base their teaching, the nurses filled out dietary survey forms similar to those used in the school work. This was done when the patient or family was first admitted to service, or soon thereafter. The nurses would then follow up these patients on subsequent visits. This approach inevitably led to instruction in budgeting food money. Development of and adherence to a satisfactory budget was difficult to secure in families on a marginal and unstable income, and there were many such families. With those upon relief the aid of the welfare workers was solicited and obtained—this almost to the point of coercion with families of known irresponsibility. Even though few families were taught to budget adequately, considerable success was achieved in emphasizing the proportion of money to be spent for various types of food and in pointing out inexpensive types of food of high nutritional value. The nurses emphasized the value of home gardens, canning at home, storage pits for staple vegetables, and the family cow or the neighbor's cow for milk. With

certain families definitely encouraging results were achieved. Interesting in this connection is the statement of one of the nurses:

"Although I would like to see many families have cows, few of them do. Most families can neither afford to buy one, nor know how to care for one. Preaching the family cow is like butting one's head against a wall. Better results were achieved in teaching families how to use evaporated milk. Many mothers did not realize that this milk came from cows, and had no idea how to use it except to pour the undiluted milk in coffee. I feel that my major accomplishment in nutrition teaching has been in securing a greater use of evaporated milk."

FOOD SUPPLEMENTS

Distribution free or at cost of certain essential foods was undertaken. The public health association handled cod liver oil and considered powdered milk. The former was purchased by the drum, distributed in the clean, sterilized whiskey bottles so readily available. Later, capsules of shark liver oil were substituted for the cod liver oil which was then becoming expensive. The distribution of capsules was cleaner, proper storage was easier, and the capsules were more acceptable than the liquid cod liver oil.

Iron was distributed or prescribed to prenatal patients with anemia. The patients for whom it was prescribed usually purchased it at their own expense. A hemoglobin determination gradually became a routine procedure at most of the prenatal clinics. The data are too sketchy and the cases too few to permit conclusions about iron medication. However, in one clinic where recent records were reviewed, about 40 per cent of the patients on admission had a hemoglobin of 75 per cent or lower, as judged by the Tallquist scale. This usually improved under treatment. It seemed that patients with a low hemoglobin were more often prone to complications of labor than were other patients.

EVALUATION

Objective evaluation of the work is difficult because of the short time that the program has been in operation. However, all but two of the 23 schools started a lunch program. It will be of value at a later date to make another dietary survey in the schools, and to compare the findings with those given here. Improved school attendance did seem to occur, particularly in the schools for colored children after a lunch program was inaugurated.

The public health nurses from their case records can list many families who have improved their diets as a result of the nutrition work of the nurses. It might be worth while, using the dietary survey technic, to determine any trends in diet of families, and especially of prenatal clinic patients, and by following certain patients through repeated pregnancies to determine whether the dietary habits of these women have improved appreciably as a result of the work done with them.

Subjective evaluation, lacking more objective data, is of interest and value. The following, from a county nurse, commands attention:

"I find that a mother who has been taught proper infant feeding takes at least part of this information over in feeding the next baby. This has not been true with my prenatal patients, however. There seems to be little if any carry over of better diet for the mother into her next pregnancy, but during any one pregnancy her diet usually improves as the result of working with her. Why there should be no carry over I do not know, except that financial means are limited, and a mother will feed her baby but do without for herself."

SUMMARY

In summary, the basic essentials for nutrition work in any county are believed to be: (1) effective leadership, to be supplied by the nutritionist of the state health department, county home demonstration agent, teachers, etc., and (2) a sufficient number of effective pub-

lic health nurses to do the family case work, assist teachers in schools, and help with the promotional activities.

The program in one county has been described in which the school lunch program was featured. The problem was defined by means of a dietary survey. Lay helpers with the survey proved to be effective propagandists for the cause of school lunches. Equipment and money were provided by the school board, organizations, and individuals. Surplus commodities were used. WPA and NYA and volunteers provided labor. All but 2 out of 23 schools were stimulated and helped to start a lunch program in which free lunches were provided for the children from indigent families as a part of the program.

Demonstrations were conducted at prenatal clinics. A home economics class for underprivileged women did not succeed. Nutrition education for the individual and family, and particularly for the prenatal patient, was conducted by nurses. The dietary survey was the foundation for this work, in which types of food, budgeting, and the value of home gardens, canning, storage pits for staple vegetables, and the family cow were all emphasized. Cod liver oil and shark liver oil capsules were provided free or at cost to selected families; and an iron compound was given or prescribed for prenatal patients with anemia. In all of this work the coöperation of school authorities, welfare workers, the county home demonstration agent, and various lay organizations was available as needed.

The experiences recorded here make it clear that nutrition work represents a long-time educational project.

NOTE: I am especially indebted to Catherine Leamy, Maryland State Nutritionist, for guidance with the nutrition work in the county and to the late Mamie Thompson, Public Health Nurse, in Worcester County, for her unusual efforts in behalf of the project.

Housing as a Health Officer's Opportunity*

HUNTINGTON WILLIAMS, M.D., DR.P.H.

Commissioner of Health, Baltimore, Md.

LEADERSHIP in organizing community health services on a modern and adequate basis is what may be reasonably expected of any health officer. There is probably no one in the Health Officers Section who has not played his part as a leader in some of the well recognized activities of health departments, such as the prevention and control of diphtheria or tuberculosis or syphilis, or general civic sanitation, including privy or sewer construction.

Times like these bring repeatedly to the health officer challenges to exert himself in less-trodden fields, and among you there have been excellent pioneer workers in studying cancer and in organizing various approaches to the complicated problem of medical care and hospital service.

Some health officers feel that, while it is difficult to control what community services are assigned to the health department, there is obviously a risk in spreading the health department butter so thin over a multitude of administrative matters that the quality of the service rendered to the people will eventually become quite unsatisfactory, not only to the people but to the health department itself.

Until a few years ago the problem of improving the housing for the poorer segments of our urban population was

not widely accepted as a health officer's responsibility in this country. During recent years, however, health officers who have been a trifle bold in approaching this knotty matter have occasionally found to their surprise an unexpected warmth of community support. Indeed, one health officer I know who ventured rather timidly in this field as an experiment, and then waited for the heavens to fall, was quite astounded to find that the better element in the real estate group in his community was not openly disturbed, and a little later the community and the health officer himself were asking the same question; namely, "Why didn't the health department become active in this field long ago?"

I should like to show that there is a real opportunity for the health officer who will recognize housing as a legitimate preventive health service reasonably to be expected from the health department by relating some of the more interesting experiences that we have recently had in Baltimore.

Even a casual review of our general nuisance abatement ordinances and certain sections of the local building code made it clear that there was ample authority for the City Buildings Engineer or the Commissioner of Health to issue orders on property owners where dwellings were found to be beyond doubt unfit for human habitation and dangerous or detrimental to life or health. A first approach just happened to result from a request from the

* Read before the Health Officers Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

rather new City Housing Authority that a very dilapidated slum courtyard be removed because one of the new Housing Authority building projects was to have its front yard just across the street from this slum unit. The owner of the property was notified by the City Buildings Engineer on the recommendation of the Commissioner of Health that, unless the properties were made safe and secure within a ten day period, action would be taken by the Bureau of Buildings under ordinance provision. This resulted in the demolition of the properties in question without noticeable protest on the part of the owner.

Some months passed by and the City Health Department through its Sanitary Section developed rudimentary inspection services aimed to discover similar rock-bottom slum conditions where dwellings, inhabited chiefly by Negroes, were frankly unfit for human habitation. At this juncture, the Health Department secured superb support from the City Welfare Department and also from the local press. *The Baltimore Evening Sun* established as one of its major interests the education of the general public in the matter of these local slum dwellings. It became customary over a period of months for the Commissioner of Health to make personal surveys in company with the City Welfare Director and the so-called "Architectural Correspondent," a very socially-minded editorial writer. The last mentioned gentleman brought with him a press photographer who had not only a good instrument but a vivid imagination.

This group, appreciating that they could not take the public to visit the worst slums, were in a reverse manner enabled to take the slums week by week to the very doorstep of the general public, and place before them, in a series of editorial page illustrated articles, information that was responsible for a phenomenal amount of public

support for the program in question. The titles of some of these illustrated press releases were as follows:

Gems of Baltimore Architecture
A Slum No More
The Great Wall of Pine Street
Early American Interior
Landscaping in a Row House District
There's Gold in Slum Housing
The Bevan Street Housing Development
The Peach Street Arc de Triomphe
Rats and a Bathtub
The Health Department's Authority To Go
After Rotten Dwellings
This House Had the Honor

The press articles in question appeared during an interval of about 18 months, beginning early in 1940. Some of them rather naturally were upsetting to the peaceful custom of allowing these worst slums to remain without attention. It soon became evident that there was a group of city officials who constituted a team with authority to take definite and suitable action in a variety of directions. It was also apparent that the team in question was very much like a group of football players who were placed on a field without uniform, without preliminary coaching or training and, under the gaze of an expectant grandstand, were called upon to produce with promptness a series of touchdowns; further, it became promptly apparent that no rules or signals had been established for their teamwork. From the early efforts it appeared as though one or another of the team at the signal secured the ball but ran in the wrong direction and made a touchdown for the opposite side.

What was necessary in the matter seemed fairly obviously to be some gentle and kindly group guidance, interspersed with much mutual toleration and patient persistence. There was thereafter little or no delay in bringing about very excellent teamwork in the group of official and nonofficial agencies that were involved in the problem.

Part way through the recent experience, a landlord refused positively to comply with the orders of the city authorities, that is, the Commissioner of Health and the City Buildings Engineer. The refusal eventually resulted in a legal battle which served as a test case. During this testing it was made clear that the ordinance provisions governing the matter were not adequate. Because of the great public interest that had resulted from the assistance from the press, it was not a difficult matter to secure the enactment of two highly desirable new ordinances. One has been given the title "Ordinance on the Hygiene of Housing." This added new sections to the city health code and authorized the Commissioner of Health to compel compliance with its provisions. The other, now known as the "Rooming House Ordinance," amended existing local legislation and greatly strengthened the authority of the city health department in preventing overcrowding of rooming houses in a manner that would be detrimental to health.

Even before the enactment of the new ordinances, the test case was won in the Criminal Court after nearly a year of legal maneuvering. The Health Department then found itself in a rather strong strategic position but without adequate personnel to make the many inspections that seemed to be needed. As an example of the conditions that had been found in rooming houses, mention may be made of one 15 room converted dwelling, housing 15 white families with a total population of 47 persons. Here 9 families shared 1 sink in the bathroom, 12 families shared 1 toilet, and 13 families shared 1 bath. The walls and toilet and steps were defective, not to mention rat infestation and accumulations of filth. Another sample was a 15 room multiple dwelling housing 5 white families. Here in 2 rooms lived a family consisting of the mother, father, and 6 children. In the

same house there were 33 occupants and of these 20 were children. There was only 1 bathroom. The tub was not available, as the connections had been removed, and there were in the whole house only one basin and one toilet. Findings of this kind when brought to public attention resulted in the addition to the City Health Department staff of two full-time inspectors to care for the great overload of work, and this made a total of 3 men devoting their entire time to housing.

It is obvious that there are many steps which lie ahead in reaching a satisfactory solution of this housing problem for the community under consideration, but a fairly good start has been made and just now it does not seem probable that there will be any decrease in Health Department interest in this important health field.

It will be of interest to health officers to know that the Committee on Housing of the Health Officers Section has been active during the past year, although not as active as had been hoped for a year ago. On May 7 last it sent a circular letter to all the members of the Health Officers Section for the purpose of telling them of the committee plans and to secure responses indicating which members of the Section were particularly interested in housing as a practical problem of health administration, as well as which members wished to keep in touch with the committee and its work. Replies were received from 40 members of the Section. Of these, 14 were in cities of 100,000 population or over, and 17 were in cities of less than 100,000 population. There were also replies from 3 state health officers, 5 health officers outside of the country, of which 3 were in Canada, and 1 district health officer from a large city.

The following brief extracts from a few of these letters will indicate their general tenor:

"My present problem is to secure legislation by which I can prevent overcrowding in lodging houses where single and double rooms are rented as apartments."

". . . housing problems in the rural sections are fairly new to me, but I would appreciate any information or publications you have on that subject . . ."

"It seems to me that this is a field in which there is a real opportunity for the Health Officers Section to be of service to its members."

"I am extremely interested in the activities of your Committee on Housing. Housing has long been No. 1 public health problem in this community and with the addition of 12,000 defense workers it has presented difficulties for which we have been unable to find a solution."

"We note with interest, the organization of a Section Committee on Housing in the Health Officers Section. . . . The preparation of the brief working bibliography, to which you refer, may well be of great assistance to any of us. . . . There are, in (this city) a large number of substandard houses now occupied and it has been practically impossible to declare them unfit for habitation and require

that they be vacated inasmuch as there are not adequate homes to which these occupants can be moved."

The replies were of great interest to the committee and it is hoped that during the coming year it may be more active and more helpful to the members of the Section.

Relationship of Mental Hygiene to a Local Health Department Program*

W. F. ROTH, JR., M.D., W. C. WILLIAMS, M.D., F.A.P.H.A.,
AND F. H. LUTON, M.D.

*Director, Williamson County Child Guidance Study, Tennessee Department of
Public Health, Franklin, Tenn.; State Commissioner of Public Health,
Nashville, Tenn.; and Vanderbilt University, Nashville, Tenn.,
and Consultant to the Child Guidance Study*

A MENTAL health program was inaugurated in Tennessee with the establishment of a Child Guidance Study, a psychiatric unit attached to the local health department of a rural county, in September, 1935. The immediate purpose of this project was a quantitative study of mental illness and maladjustment in a rural community, with the ultimate objective of devising and demonstrating methods for the inclusion of mental health procedures in the programs of existing public health agencies. The approach to the initial objectives and the results of the preliminary studies have been described in other papers from the study.^{1, 2} The purpose of this paper is to present a progress report on a program designed to demonstrate the possibilities for the training of personnel and the application of therapeutic and preventive mental health measures through established public health agencies.

THE SET-UP

Although our ultimate goal is to pro-

vide a state-wide mental health service, the first stages of the program have been confined to a single county. It is our opinion that the county is perhaps the best basic working unit through which the mental health program can be applied on a state-wide basis. The experience gained in the one county used as a proving ground should determine largely the procedures to be followed, in extending mental health services to other counties of the state.

Williamson County, Tenn., is a fairly typical agricultural county of approximately 25,000 population. It has had a local health department since 1921. For the past twelve years the health unit has had a staff which, according to present-day standards, is adequate to meet the usual public health requirements of a rural county. For the past six years the Child Guidance Study, though administratively a unit of the State Department of Public Health, has functioned as a branch of the county health department. The regular personnel of the study consists of 5 full-time workers (director, 3 nurses, and secretary) and a consultant. The director and consultant are psychiatrists. The nurses have had varying degrees of special training in the fields of psychology, psychiatry, and psychiatric social work.

* Read before the Health Officers Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

The Child Guidance Study has been financed by grants from the International Health Division of the Rockefeller Foundation.

THE MENTAL HEALTH PROBLEM

The scope and extent of the problem of mental illness and maladjustment are gradually receiving due recognition. People are coming to an appreciation of the importance of mental health for physical well-being and the social and economic life of the nation. In appraising the problem of mental health we must take cognizance of groups other than those with frank mental disease. All personality deviations that render human beings less happy, less efficient, and less able to adjust themselves to established social amenities must be taken into account.

Current literature is studded with communications that exemplify the infiltration of psychiatry into all fields of medical work. Many authors, particularly Bassett,³ have pointed out the broader community aspects of mental hygiene. Various surveys in this country and abroad have given some indication of the prevalence of mental and personality disorders. Among the most thoroughgoing and illuminating surveys are those of the Mental Hygiene Study of the Eastern Health District of Baltimore, Md. That survey was first described by Fairbank⁴ in 1936, at the

annual meeting of this Association. Subsequent reports by Cohen and Fairbank^{5,6} and Freeman and Cohen⁷ showed that in the urban area of about 56,000 population studied, approximately 4½ per cent of the inhabitants had definite mental or personality disorders, while an additional 2½ per cent presented conduct and behavior disorders, the majority of which could be classified as mental health problems. Recently, Lemkau, Tietze, and Cooper⁸ published a brief review of the Eastern Health District Mental Hygiene Study, in which some of the possibilities for therapy and prevention were outlined and the possible use of public health personnel in such work was suggested. While not all of their findings are applicable to the mental health situation in a rural community, their prevalence statistics are revealing and, interestingly enough, correspond rather closely to ours.

In Williamson County, the psychiatric survey made by our study² revealed that on September 1, 1938, there were at least 1,721 persons, or 69.4 persons per 1,000 population, whose condition merited psychiatric inquiry and consideration of treatment or pre-

TABLE 1

Psychiatric Classification of 1,721 Residents of Williamson County with Rates per 1,000 Population, as of September 1, 1938

<i>Classification</i>	<i>Number of Cases</i>	<i>Rate per 1,000</i>
Total	1,721	69.4
"Active" Cases		
Psychotic and post-psychotic	914	36.8
Psychoneurotic	121	4.9
With conduct or behavior disorder	89	3.6
With psychopathic traits	285	11.5
With special personality type	152	6.1
Mentally retarded *	208	8.4
With organic conditions, handicapped, miscellaneous	19	0.8
	40	1.6
"Inactive" Cases		
Post-psychotic	807	32.5
Formerly psychoneurotic	55	1.4
Formerly with conduct or behavior disorder	10	0.4
With psychopathic traits	129	5.2
With special personality type	34	1.4
Mentally retarded	126	5.1
With organic conditions, handicapped, miscellaneous	184	7.4
	289	11.7

* Includes all cases of mental retardation presenting active problems which are not included in the classifications higher on the list.

FIGURE 1—Distribution of active cases on September 1, 1938, Williamson County, Tenn. (Districts 3, 10, and 19 had intensive survey)

ventive measures. Of these cases, 53 per cent were classed as "active" mental health problems (see Table 1). The remaining 47 per cent, while classed as "inactive" were regarded as potential problem cases. The rate for active cases was 36.7 per 1,000 population; and if all cases of mental retardation had been included in the active group, this rate would have been increased to 44.5 per 1,000 population. Furthermore, it was judged that, in at least 604 of the cases (24.4 per 1,000 population), the mental disorder or personality maladjustment was of such magnitude that psychiatric treatment was urgently indicated. Moreover, there is much evidence that these prevalence figures were too low; in three representative areas of the county that were intentionally subjected to more

searching survey, the case rates were almost twice as high as the rates for the rest of the county (see Figure 1).

Every community has its quota of individuals with mental disorders and personality deviations. Every community agency, in one way or another, faces the problem of dealing with this group of people, and the public health organization should be particularly concerned with them. Among those with more serious mental disorders, the psychotic, pre-psychotic and post-psychotic present special problems of management in home and community. The psychoneurotics require a distinctive type of approach by those administering medical care. The epileptics need careful supervision of drug therapy and general hygiene. The feeble-minded must be managed quite differently from other

people. The spastics and all others, mentally or physically handicapped by organic defects, should be given the benefit of appropriate guidance and corrective measures, with constant observation of the principles of mental hygiene. Children presenting habit patterns of faulty nervous and emotional control and persistent behavior disorders should have special attention, that they may be saved, if possible, from becoming misfit adults. Last and largest, comes that great group of adults who cannot properly be classed in any of the above mentioned categories but who are emotionally warped or unstable and/or intellectually handicapped; these generally provide our most serious problems of conduct disorder as well as innumerable instances of uncoöperative, unreasonable, and antagonistic behavior.

In our opinion the people included in these classes have a disproportionately high representation in that oft-cited "one-third of the nation" that goes without adequate food, clothing, shelter, and medical care, and they undoubtedly make up the great bulk of that segment of our population. The fact that these people lack a fair share of the benefits of modern civilization is not so much an indictment of our way of life and our system of medical care as it is an indictment of our tendency to treat all men as equal *and therefore the same*. Mental disorders and personality deviations should be recognized and should be accorded appropriate management. Public health workers, to attain the maximum of success in their programs, must know when to adopt a policy of individualization of approach; they must recognize the personal variations in people and, in addition to employing specific procedures for mental health, they must adapt their standardized technics to meet individual situations.

Certain public health activities which are more or less universally established

provide splendid opportunities for constructive work along mental hygiene lines. In the health courses to classes of high school students—the premarital group—public health physicians and nurses are in a position of unequalled vantage for promoting mental health. While carrying out their routines of prenatal and postnatal care and conducting well baby and preschool clinics, they are in a most strategic position for recognizing and correcting conditions that are mentally unhygienic as well as those that are physically detrimental. The object of our mental health program is to devise ways and means of making the most of such opportunities.

THE DEMONSTRATION PROGRAM

Our plan for a mental health demonstration program to be tied in with the routine activities of a local health department includes four principal lines of procedure as follows:

1. A demonstration psychiatric and mental hygiene clinic, serving the county
2. A special program of training in psychiatry and mental hygiene for the regular public health personnel of the county, including:
 - a. A short didactic course in the fundamentals of psychiatry
 - b. Demonstration of problems at weekly staff conferences by use of clinic cases
 - c. Routine individual and group conferences of public health nurses with a case work supervisor
 - d. Joint visiting in the field by public health and psychiatric personnel
3. Psychiatric education of other professional groups
 - a. Practising physicians of the community
 - b. School teachers of the county
4. Community education through:
 - a. Talks to Parent-Teacher Associations and other lay groups
 - b. Newspaper articles

Part of this program has been put into effect during the past year. The separate phases of the program and accomplishments to date will be discussed

as each of the procedures is presented.

Demonstration Clinic—Our knowledge of case material, our contacts with local agencies and especially the well established working arrangement with the local health department and the practising physicians of the community, were used to provide a source of cases for this clinic. The clinic was organized and planned to conform to accepted standards for psychiatric and mental hygiene clinics, utilizing the specialized personnel of the study to provide essential clinical services. The Director and Consultant furnish clinical psychiatric services; one of the nurses with special training functions as clinical psychologist; and all of the nurses function as psychiatric social workers, with the one accredited by graduation from a school of psychiatric social work serving as case work supervisor.

It was arranged so that approximately the same amount of time should be given to clinic appointments as would be available if the clinic were part of a travelling unit spending one day per week in the county. This amount of clinic service represents the absolute

minimum required to carry on work of the desired quality. Incidentally this conforms to the policies and methods of the Bureau of Mental Hygiene of the Connecticut State Department of Health, which have been described by Cunningham.^{9, 10} Actually, during the first year of our clinic's operation, there have not been enough acute or "active" cases referred to provide the maximum case load that could be handled by a clinic operating on a one day per week basis. Advantage was taken of the extra time available to carry on follow-up studies of as many of the post-psychotic individuals as could be obtained and brought to the clinic. The statistics on the first 12 months of the clinic's operation are given in Table 2.

In addition to the considerable number of inactive cases admitted to the clinic, other atypical features are noted in the large number of patients with convulsive disorders and the small number of children of school age. Both of these facts are logical consequences of the situation. As the clinic service becomes better known and well estab-

TABLE 2

Classification of Cases Admitted to the Demonstration Clinic During the Period October, 1940–September, 1941, by Age

Classification	Total Cases	Age in Years				
		0-4	5-14	15-24	25-49	50-99
Total cases	94	5	19	15	35	20
<i>"Active" Cases</i>						
Psychotic, pre-psychotic, post-psychotic	23	1	13	9
Psychoncurtic	15	2	7	6
Psychopathic personality with conduct disorder	4	1	3	..
Epileptic *	16	1	4	7	2	2
With personality and behavior problems of childhood	6	..	6
Mentally retarded †	5	1	3	1
With organic conditions, handicapped, miscellaneous ‡	15	3	6	2	3	1
<i>"Inactive" Cases</i>						
Post-psychotic	10	1	7	2

* Includes all cases of idiopathic epilepsy (except for 2 classed as post-psychotic) and other cases (including 2 mentally retarded) in which convulsions were the outstanding complaint.

† Includes all mentally retarded individuals not classified in other categories; in most instances cases referred for diagnosis. Includes mongolism.

‡ Includes cases of tic and habit spasm and of cerebral palsy, with or without mental retardation and/or convulsions.

lished a greater variety of cases, and a larger number of cases presenting minor problems, will be referred. It has been easy to obtain the cases with convulsive disorders because in such cases we have an example of a condition to which little stigma attaches and in which the disorder is quite objective.

On the whole, the results obtained with the clinic have been gratifying. It provides the county with facilities for prevention and treatment which, in our opinion, are at least the equal of those afforded by established services functioning in rural areas elsewhere. Moreover, the community is learning to take advantage of the services offered.

Personnel Training Program—The need for more undergraduate training in psychiatry and mental hygiene for both medical and nursing students is generally recognized. In instituting any program of mental health work in the average community, one of the requisite first steps is to compensate for the deficiencies of personnel training which have existed in the past. Hence, our early effort to supply postgraduate training in some manner necessarily took precedence over practically all else. The program was begun with a didactic course in the fundamentals of psychiatry which was presented by members of the study personnel. In six evening sessions, supplemented by the reading of recommended material which had been provided, the physicians and nurses of the health unit were given a sound though brief introduction to the subject. Following this, clinical teaching was begun through the medium of the regular staff conferences. At these weekly conferences all members of the medical and nursing personnel of the county health department have attended regularly. They hear case histories presented, patients interviewed, and discussions of diagnosis and treatment by the psychiatric personnel. To date this type of instruction has been

well accepted and has apparently furnished a most stimulating and educational experience for the public health workers.

To supplement the teaching program described above and to give the nurses instruction in the technics of case work, an individualized approach to people, we have inaugurated a system of individual and group conferences, with the case work supervisor of the study serving as consultant. Once each week individual conferences are scheduled with each nurse of the local health department. These interviews enable the nurses to bring up for discussion cases which they encounter in their routine work and which seem to present mental health problems. The case work supervisor, through her suggestions and comments, attempts to stimulate more study of the cases presented and to guide the nurses to a better understanding of each individual situation. Suggestions as to management are given, and the progress with each case is followed from week to week. Every two weeks there is a group nursing conference for the discussion of special problem cases of interest and of educational value to all. The nurses are encouraged to do collateral reading, with particular attention being given to the selection of reading materials and interpretation of their contents. In addition to the scheduled conferences, the case work supervisor is available daily for informal discussions without special appointment.

The results of these conferences to date have been highly satisfactory. While they have brought out the need for more psychiatric education of public health officers and nurses in their undergraduate and postgraduate training, the interest shown has indicated that much can be accomplished by practical field work of this sort. The use of clinical material is a distinct advantage in the training program.

Education of Other Professional Groups—There has been little time to carry on a formal program under this heading. Physicians and teachers of the community are well acquainted with the project; there have been many contacts between them and members of the study and local health department personnel, and a good deal of coöperative and consultant work on special cases has been carried on. Considerable material of an educational nature has been presented during the past years, but without any attempt at a formal program of psychiatric education. From time to time papers have been read before the county medical society on various phases of the work of the study and on special topics in the field of psychiatry. Similarly talks on mental hygiene have been made before teacher groups. The present plan is to proceed with an organized program for the presentation of psychiatric material to both physicians and teachers. The possibility of a didactic clinical course for the local physicians is being considered. As soon as possible it is planned to establish a regular program in coöperation with the teachers. Such a program would probably include as its main feature periodic meetings or conferences with the teachers; it would be carried out along much the same lines as the program in a rural Massachusetts county, recently described by Abbott and Gardner.¹¹ It is our opinion that physicians and school teachers generally are interested in problems of mental health and that an educational program following conventional lines will succeed in almost any community, providing tact and good judgment are used and the general methods are adapted to the individual locality in question.

Community Education—Here again conventional lines would be followed. To date we have not been able to undertake any formal program. Talks

to Parent-Teacher Associations and similar organizations and regular newspaper articles of elementary content on mental health topics would be the chief media of approach. The fact that all members of the medical and nursing personnel of the local health department are already regarded as leaders and teachers is quite naturally an asset in any such program of educational work.

PLANS FOR THE FUTURE

It no longer seems necessary to belabor the point of the responsibility of public health agencies for participation in work for better mental health. Vogel¹² has recently treated this subject in a most convincing fashion and has outlined recommendations for state health departments. Our local program has been devised with the idea of eventually extending it over a wider area, first perhaps to a circuit of several counties that could be handled by a single travelling psychiatric unit, and eventually to all counties having full-time local health departments. While such a program will inevitably entail additional expenditures, it should be pointed out that the federal government, through the U. S. Public Health Service and the Children's Bureau, is assisting in the financing of mental health programs. There are funds already available from the agencies mentioned which may be used for purposes of a mental health program of the sort we have in mind.

There is no doubt that all interested community agencies should take a part in any program for mental health. However, it is our opinion that, in rural areas where there is not already an established specialized agency rendering psychiatric and child guidance services, the local health department is the logical agency through which this and other preventive programs should be undertaken because:

1. It is a fundamental principle that psychiatric work should be carried on under medical supervision.

2. The local health department, where situations comparable to that in Tennessee obtain, is an outstanding social agency and through its general services comes in contact with cases from birth to death.

3. The local health department's work is closely coördinated with that of the school system. Obviously, the school population provides one of the most fruitful fields for work toward mental health.

4. Through its close working relationship with practising physicians, the health department has opportunities for working with cases that might be denied other agencies.

5. The health department has the advantage of offering a generalized service. This makes it possible to incorporate a psychiatric and mental hygiene clinic with the other activities of the department, thus avoiding the stigma that sometimes attaches to a separate and distinct unit.

6. Through its extensive coverage of a county and its contacts with the majority of the families, the local health department can serve as a valuable adjunct to the state mental hospital system. In situations where that system lacks adequate social service facilities, the health department can compensate for the deficiency.

7. The health department is the ideal agency to provide local headquarters for a travelling clinic unit.

8. The local health department can render the suggested psychiatric and mental hygiene services more economically than can any other agency.

SUMMARY

1. The mental health problems confronting the community are enumerated.

2. A practical demonstration program of mental health activities, coördinated with and integrated into the activities of a local health department, is outlined.

3. An account is given of a field experiment in the provision of psychiatric and mental hygiene clinic facilities through a local health department.

4. A practical method of providing much needed postgraduate instruction in psychiatry and mental hygiene for public health medical and nursing personnel is described.

5. A plan is outlined for the extension—through the local health department—to other groups in the community, of a program of education for the promotion of better mental health.

6. The possible application, over large rural areas, of the procedures being demonstrated is discussed, and the advantages of mediating mental health services through the local health department are enumerated.

Thiamin Content of Milk in Relation to Vitamin B₁ Requirement of Infants*

ELIZABETH M. KNOTT, PH.D.

Department of Pediatrics, University of Chicago, Chicago, Ill.

THE thiamin content of milk is important since it is the only natural source of vitamin B₁ available to the young infant. There are, however, complications which make thiamin assays on milk difficult. With biological assays, if the curative technic is used, it is difficult to get the depleted rats to consume the quantity of test dose that is necessary; if growth technics are employed, the basal diets must be completely adequate except in thiamin so that the resulting growth is due solely to the thiamin content of the test dose, but milk doses introduce the problem of added caloric ingestion which may affect growth. With thiochrome assays on milk the problem is also complex, since thiamin may be lost if proteins are precipitated, and the absorption and elution of the vitamin from the decalco column may not be quantitative. In our study we have employed all of these methods and are also investigating the application of the fermentation technic. The results reported here are based chiefly on growth assays, since thus far these have proved to be the most reliable.

Chart 1 compares results for pasteurized milk, boiled milk formulae, evaporated milk, and breast milk. The formulae were prepared from pasteurized milk which had been boiled for 3 minutes. The average thiamin content of these formulae was 24 micro-

grams per 100 ml. of milk, in contrast to the average of 26 μ g. obtained per 100 ml. of pasteurized milk. The boiling for 3 minutes thus had caused a loss of 8 per cent in the vitamin content. The range of thiamin for these pasteurized and boiled milks was from 18 to 35 μ g. per 100 ml. The evaporated milks tested had a slightly lower range from 13 to 27 μ g. of thiamin, with an average value of 19. The data for these evaporated milks have been calculated on the basis of reconstitution with equal parts of water to make comparisons easier between the different types of milk. The breast milks tested came from 17 different women. The thiamin content was surprisingly low, ranging only from 3 to 18 μ g. per 100 ml. of milk, with an average of 9 μ g. There may be several explanations for the low thiamin content of human milk. In the case of one woman whose milk was tested on four different occasions the milk consistently had high thiamin except during one week when she was ill and her milk contained only 20 per cent of its previous thiamin value. Diet is undoubtedly the most important factor in influencing the thiamin content of breast milk. To support this theory was the observation of a trend toward lower values for thiamin for some of the women who had but limited knowledge of fundamental principles in nutrition. Some preliminary studies have been done with supplementary thiamin for these women, but one week of increased intake has not been enough to

* Read before the Food and Nutrition Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

VARIATIONS IN THE THIAMIN CONTENTS OF MILKS

CHART 1

produce increased excretion of thiamin via the mammary glands. It is presumable that cow's milk is richer than human milk in thiamin because the cow can utilize thiamin which has been synthesized in her rumen.

Chart 2 shows in more detail the effect of processing on the thiamin content of evaporated milk. Raw milks and their corresponding evaporated milks were sent by special delivery direct from the factory to the laboratory and were assayed simultaneously. Destruction of vitamin due to the processing of

evaporated milk ranged from 23 to 35 per cent for the four lots of milk tested. Further loss of thiamin occurred during storage of these evaporated milks. The amount of destruction varied with different milks, but reached 50 per cent after 1 year for two milks, although another milk showed loss of one-half its original vitamin content in 2 months' time. This destruction upon storage is presumably more rapid during the first few months and eventually reaches an equilibrium. The rate varies for each lot of milk and is roughly indicated by

THE THIAMIN CONTENT OF MILK
EFFECT OF EVAPORATION AND STORAGE

CHART 2

the lines connecting the separate assays on the chart. It must be noted, however, that the twenty-five commercial samples of milk representing seven different brands, in general had higher contents of thiamin than the four lots stored in our laboratory. The age of these commercial milks was approximately $3\frac{1}{2}$ months, which is an average elapsed time between the manufacture and retailing of evaporated milk. The destruction of thiamin in evaporated milk is influenced by the degree and duration of heat during processing, the temperature during storage, and the pH

amount of thiamin excreted in the urine has been plotted against the level of intake for that metabolism period. At low levels of intake the infants excreted consistently low amounts of thiamin. At 80 units or more daily intake the thiamin appeared in the urine in larger quantities. Above 140 units of daily thiamin, the vitamin was excreted in still larger quantities, and it was apparent that more was being fed than the infant needed. From these data we might conclude that an intake of about 80 units of thiamin meets the infant's immediate needs and above this level of

VITAMIN B₁ METABOLISM STUDIES ON 12 INFANTS AGE 1-6 MONTHS

URINARY THIAMIN INCREASED, AT FIRST BY STEPS (—) THEN RAPIDLY, AS INTAKES WERE INCREASED

of the milk. That this destruction is a simple cleavage of the thiamin molecule into pyrimidine and thiazole was shown when one sample of old evaporated milk was assayed for pyrimidine as well as thiamin content and total values found which were identical with the vitamin B₁ content of the original raw milk.

In order to determine the significance of the thiamin content of these different types of milk, the metabolism of thiamin in the infant's body has been studied. Chart 3 summarizes the results of urinary excretion of thiamin when the infant has been given different levels of supplementary thiamin. Each dot on the chart represents data obtained during a 5 day period. In all, 12 healthy infants were studied for a total of 104 periods. The average daily

intake excess begins to appear in the urine. We do not know, however, whether or not 80 units represents the optimum thiamin requirement for the infant.

Another approach to the problem of requirement has been made by studying blood cocarboxylase levels. Since cocarboxylase is the functioning form of thiamin in the body cells, its estimation in blood cells should give an indication of the supply throughout the body. After several hundred determinations, during healthy as well as pathological conditions, we have concluded that about 5 μ g. of cocarboxylase per 100 ml. of blood is a normal value for health. Chart 4 shows the correlation between blood cocarboxylase, dietary thiamin, and symptoms in an adult.

CORRELATION OF BLOOD COCARBOXYLASE WITH DIETARY THIAMIN AND SYMPTOMS IN AN ADULT

CHART 4

This person does not absorb thiamin well from the digestive tract, so that a normal diet gives subnormal blood levels. The 3.5 µg. of cocarboxylase per 100 ml. of blood is not enough to protect against the sudden strain of illness, strenuous exercise, or excess carbohydrate diet. Symptoms of muscle cramps, muscle weakness, and fatigue were definite when the blood vitamin dropped to 1.0 µg. A feeling of well-being was outstanding when blood levels had been raised above 5.0 µg. by use of supplementary thiamin.

Chart 5 gives results for a few infants. In general, values tended to decrease from a level of 5 or more µg. shortly after birth to levels between 3 and 4 µg. Lowest levels were found for infants receiving manually expressed breast milk. The data for two of these infants are given more in detail in Chart 6. The type of milk, amount of thiamin intake, and age of the infants are indicated across the bottom of the chart. On evaporated milk formulae the blood decreased from an initial level of more than 6 µg. to 4.5 and 3.8 µg. Breast

INFLUENCE OF TYPE OF FEEDING ON BLOOD COCARBOXYLASE

CHART 5

BLOOD COCARBOXYLASE LEVELS IN ARTIFICIALLY FED INFANTS

milk feedings for the next 5 weeks brought the values down to 1.0 and 0.5 $\mu\text{g.}$ Subsequent feeding of evaporated milk slowly caused an increase in blood cocarboxylase to 4.4 and 3.6 $\mu\text{g.}$, but the more optimum level of 5 $\mu\text{g.}$ was only reached after supplements of pure thiamin were included in the formulae. The infant whose blood responded best to his evaporated milk feedings received 190 $\mu\text{g.}$ or 63 units of thiamin daily in the milk. This level of intake is not far from the level of 80 units at which excess thiamin began to be excreted in the urine. It thus appears that, although intakes of approximately 200 $\mu\text{g.}$ in the present study could not maintain the 5 $\mu\text{g.}$ of cocarboxylase which we have come to consider optimum, the amount of vitamin B₁ furnished by milk formulae apparently did produce the fairly satisfactory level of 3–4 $\mu\text{g.}$ This level is adequate unless some unusual fever or metabolic strain increases the metabolic needs for thiamin. The milk thiamin for artificially fed infants can therefore presumably carry the burden of thiamin requirement for the young infant until cereals and other additional foods are included in his diet. It must be emphasized, however, that during times of

stress supplementary thiamin will be desirable as a safety factor.

An additional comment is necessary concerning infants receiving breast milk. According to our assays this type of milk cannot furnish 200 $\mu\text{g.}$ of thiamin daily. Nursing infants studied have usually had blood cocarboxylase levels between 3 and 4 $\mu\text{g.}$, comparing well with those receiving milk formulae. On the other hand, those infants of our study receiving manually expressed breast milk showed lower levels of blood cocarboxylase. It may be possible that the thiamin content of the breast milk was reduced during the 2–4 days of storage before it could be fed. We know that cleavage of thiamin occurs more rapidly in more alkaline solutions. The average pH for our breast milk samples was 8.1, in contrast to values of 6.8 for pasteurized milk and 6.2 for evaporated milk.

Further studies on the thiamin content of breast milk and its adequacy for infant feeding are now in progress at the University of Chicago.

Additional data available as this paper goes to press show breast milk thiamin values to be higher than our earlier work indicated. Average thiamin content for women successfully nursing young infants was 20.1 $\mu\text{g.}$ per 100 ml.

Present Status of Research in Cancer*

CARL VOEGTLIN, PH.D.

Chief, National Cancer Institute, National Institute of Health, U. S. Public Health Service, Bethesda, Md.

I SHALL attempt to discuss a complex subject in a very short time. Some of the statements will appear dogmatic, simply because it is impossible to present all of the supporting evidence.

In order to have a proper perspective, let us go back about 40 years to the beginning of experimental cancer research. At that time the best medical textbooks confined the discussion of cancer to a description of the gross pathology of tumors, to a rough classification of cancers according to tissues and cell types involved, to a crude outline of the growth and spread of cancer in the body, and to various speculations on the cause of cancer, such as Virchow's conception of cancer as a disease of cells caused by chronic irritation, or Cohnheim's hypothesis, according to which certain cells during embryonic development lose their physiological relations to other cells and later on for unknown reasons become malignant. Some physicians still held to the view that cancer is a disease of the blood, and others that it is due to a specific infectious microorganism. The possibilities of x-rays and radium in treatment had barely been recognized. There were no special laboratories and institutes for the experimental study of cancer. Statistical data on cancer mortality and incidence did not exist for the United States.

What is the present situation? From recent statistical studies of the U. S. Public Health Service, we know that the crude cancer mortality rate has been gradually increasing, a fact which is largely accounted for by the increase in the average longevity resulting from a better control of other diseases. We do know that the risk of cancer increases with age. The same is true of the mortality from spontaneous cancer in inbred strains of mice. Here, also, the mortality from cancer of the breast, lung, or liver increases rapidly in middle and old age.

Studies on human cancer incidence indicate that there are about 3 living cancer patients for each death from cancer. On this basis there are now in this country 450,000 persons with cancer. It is quite obvious that the importance of cancer as a major cause of death will continue to increase, unless better control measures are discovered by research.

What has cancer research accomplished until now?

Beginning in a small way, but gaining momentum, especially during the last decade, there have been discovered an enormous number of facts. The significance of some of these facts has become clear, as I shall show presently. To begin with, exhaustive research on cancer in mammals has conclusively demonstrated that cancer is not caused by a specific organism. In other words, cancer is not of an infectious nature, as, for instance, is tuberculosis. This

* Read before the Health Officers Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., on October 15, 1941.

should finally allay all fear on the part of members of the patient's family of contracting the disease by contact with the patient. On the other hand, it is well established that cancer can be transmitted from one animal to another under special conditions, *i.e.*, by inoculation of living cancer cells from one mouse into another of the same hereditary constitution. However, these cancer cells fail to proliferate progressively in mice with a different heredity or in other species of animals, as, for instance, rats, guinea pigs, or rabbits. Furthermore, all attempts to produce cancer in animals by the inoculation of human cancerous tissue have failed. Moreover, we know that the susceptibility for spontaneous cancer in different inbred strains of mice differs for different types of cancer. Thus we have mouse strains with a high or low incidence of cancer of the breast, lung, or liver. We conclude, therefore, that cancer in man and other mammals is a disease of the cells of the body and that the disease is highly specific for each animal species and for each cell type.

What do we know about the conditions under which normal cells become cancer cells? There is irrefutable evidence that excessive exposure to x-rays, radium, or ultra-violet light can produce cancer. I recall to your attention the deaths from cancer of pioneer radiologists and of the girls who were engaged in the manufacture of luminous watch dials. From a practical viewpoint it is, therefore, important to protect the personnel in radiological clinics and x-ray operators in industry against excessive doses of x-rays or radioactive material. A recent survey of clinics by the National Cancer Institute has demonstrated the practicality of reducing exposure to x-rays and radium to 0.1 roentgen or less per day by proper construction and handling of apparatus. Similarly, we can prevent certain

"occupational cancers" which are caused by chemicals. For example, β -Naphthylamine is extensively used in the manufacture of aniline dyes. Experiments on dogs have shown that naphthylamine causes cancer of the urinary bladder, which is prevalent in dye factory workers.

To coal soot and coal tar were attributed cancer producing properties for 140 years, until in 1915 it was proved that long continued application of coal tar causes skin cancer in rabbits and mice. This important discovery made possible the prevention of skin cancer in workers handling coal tar on roads and in industry. Later, the active chemical in coal tar was isolated in pure form as 3,4-benzpyrene. This was followed by the recognition of the cancer producing properties of some 250 chemicals. One or two of these chemicals were formerly used for coloring butter and are known under the common name "butter yellow." Some of these chemicals have been of great value for the production and study in experimental animals of almost every kind of cancer known to occur in humans. This work has led to the following conclusions:

The injection of minute amounts of the powerful chemicals into the tissues of susceptible animals produces cancer, often within a few months. This is not necessarily accompanied by chronic irritation of the tissues. Once cancer has been produced, the presence of the chemical is no longer necessary for the continued growth of the cancer. In other words, the chemical is needed only for the transformation of normal into cancer cells. Most of the cancer producing chemicals are foreign to the animal body. However, it can be assumed with considerable justification that the naturally occurring cancers in human beings and animals may be caused by chemicals produced within the body. In fact, we know that large doses of female sex hormones can induce

cancer of the breast in animals. The discovery of other cancer producing constituents of the animal body is now one of the most important tasks of cancer research. Success may well lead to the effective prevention of certain types of cancer. Furthermore, animal experimentation, as well as clinical study, has firmly established the view that cancer is not a single disease but a group of diseases with some common characteristics.

Radium, x-rays, ultra-violet light, and chemicals all can produce cancer of the skin, yet these agents do not seem to have another property in common. If we knew how any of these agents cause the transformation of normal into malignant cells, we obviously should have a key to the causation of cancer. This problem is being studied.

In order to comprehend why cancer kills, we must try to explain why cancerous tissue grows progressively and why it invades and destroys normal tissues. A satisfactory explanation of this question may lead to more effective curative methods. Work at the National Cancer Institute has shown that these problems can be attacked successfully by the application of biochemical knowledge and methods. We have found that the growth rate of certain cancers in animals can be strikingly slowed up by maintaining the animals on diets partly deficient in essential components, such as certain amino acids or vitamins. The time may come when it will be possible to devise diets which will control the cancerous growth in patients.

Very important studies are under way to detect differences in the chemical composition and the activities of enzymes between cancerous tissues and the normal tissues from which the cancers are derived. Already striking

differences in the activities of certain enzymes have been discovered.

Quite recently we have found that a cancer of the liver transplanted under the skin will cause a profound reduction in the activity of the enzyme catalase in the supposedly normal liver of the animal. This proves that the growth of the cancer strikingly modifies the biochemistry of a tissue far removed from the cancer. In other words, the effects of the cancer are not confined to local effects, but evidently there are also definite manifestations involving the body as a whole. In these respects cancer research is entering rapidly into a stage similar to that which nutritional diseases occupied some 35 years ago, just before the discovery of the vitamins and enzymes which are so important for normal nutrition and for the prevention of nutritional diseases.

I shall be content if this paper has convinced you that cancer research has already accomplished a good deal and that further intensive work will be increasingly productive of new knowledge. Health officers are, of course, interested in practical applications. The whole history of medicine shows, however, that what at a given time has no practical use may be found useful later on. You also can contribute to cancer research by improving the reliability and usefulness of cancer death certificates. Such data are of great value for statistical studies.

In conclusion, let us never forget that cancer in time of peace or war is one of the most ruthless killers, accounting yearly for more than 150,000 deaths in our country. The misery caused to the patients and their families is enormous; so is the cost of medical care. I am confident that research will gradually solve the cancer problem.

Education in Nutrition as Part of the Maternal Health Program*

CHRISTINE A. HELLER

Food Economist, School of Nutrition, Cornell University, Ithaca, N. Y.†

THE main effort in any nutrition program is to bring about desirable changes in food buying, preparation, and consumption. All efforts in staff education and coöperation with other agencies are directed toward this one goal: to have the newer knowledge of nutrition reach down to every family in the community. But it is well known that marked sectional differences in food customs exist in the United States and that in some sections large groups of people adhere closely to a limited food pattern with a definitely local character. Thus the majority of the citizens of New Mexico have a fixed traditional dietary.

Before attempting to change such traditional food patterns the nutritionist will need considerable self-education. This is especially true if she has not previously lived in the state where the pattern prevails or has had no experience in a state with similar customs, needs, and problems. She must become acquainted as rapidly as possible with the different food patterns among her various groups. She must find out what contributions the traditional foods make to the total daily dietary. She must know how these food patterns measure up to the present-day nutrition standards. She must

know how the foods are traditionally prepared and determine whether or not these methods rob the foods of their nutritive value. She must learn something about the physical status of the people. From information available from records of maternity service clinics, well child medical conferences, school children's clinics, selective service examinations, surveys, etc., she should try to ascertain what are the outstanding nutritional needs. She should acquaint herself with family, community, and state resources in order to be practical in her suggestions for change or supplementation.

But this is not all the information she needs. She must acquaint herself with the attitude of the general public toward the food habits of the cultural groups living in their midst. She needs to consider the families themselves—their attitudes, prejudices, and superstitions. She needs to know what previous work has been done with the people. Only then is she prepared to work effectively.

TEACHING THE MIDWIVES

New Mexico was first colonized by the Spaniards over 400 years ago. Their descendents are called Spanish-Americans as distinguished from the later settlers, who are called Anglo-Americans. This seems an unusual situation in the United States, but topography of the country and the prevailing poor roads have tended in the past to isolate

* Read at a Joint Session of the Food and Nutrition, Maternal and Child Health Sections and the Oral Health Group of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

† On leave from the State Department of Health, Santa Fe, N. M.

the Spanish peoples, who have therefore remained a distinct cultural group. Because of this and the consequent lack of medical facilities, most of our Spanish mothers were cared for by untrained midwives. For the past 4½ years the maternal and child health plan in New Mexico has included a training program for the midwives. When a nutritionist was added to the state staff, the midwife consultant asked her to conduct some nutrition demonstrations as part of this training program.

There are almost 800 midwives in New Mexico, most of them Spanish-Americans, speaking Spanish. The midwives are often leaders in their villages and they have been the ones who carried on the old traditions and customs, especially those concerning the care of mothers. In regard to food, some of their practices have been good—others not. For instance, for the first few days after delivery many of the midwives practically starve the mothers. Since the midwives are such influential people, we felt that if we could convince them of the importance of desirable food practices for the expectant and nursing mother, we could more easily effect other necessary changes.

Nutrition demonstrations for the midwives have been held in many New Mexico villages. The midwives are asked to bring their patients to the meetings whenever possible. The public health nurse also attends, and thus has an opportunity to observe a demonstration in the teaching of nutrition. The nurse asks questions and contributes to the discussion along with the midwives and expectant mothers. These demonstrations have proved an effective way for the nutritionist to work in the field and learn at firsthand some of the nutrition needs and problems of New Mexico. They have given her an opportunity to come into intimate con-

tact with the people of the state. They have also given an effective technic in staff education in that they show the public health nurse how to make practical application of nutrition knowledge. One nurse, discouraged because of the economic conditions existent in her district, said: "Frankly, before we had the nutrition classes for the midwives, I didn't think we could do anything in nutrition, even though we recognized it as one of our major problems." I have subsequently visited her district several times. The last time it was to work out a demonstration nutrition unit with the nurse and one of the teachers in a one room school. Incidentally, both nurses in this district make nutrition a regular part of their prenatal and postpartum home visits, as well as a part of their school health program.

ADAPTING THE PROGRAM TO THE TRADITIONAL FOOD HABITS

The response to this teaching program has been most encouraging. We have attempted to take the traditional food pattern of corn, beans, chili, and tortillas and point out to the mothers and midwives the good features of the diet. For instance, nothing pleases them more than to know that pinto beans are a good blood building food or that chili is an excellent food. In suggesting supplementation such as milk, cheese, etc., we have been able to point out to them that these foods are not new to the Spanish diet; that they used to be in the old Spanish diet when every family had a cow or goat and a garden. Some of the older midwives can remember when this was so.

We usually emphasize only one particular reason why these foods are necessary. For instance, we stress milk because it is the best bone and tooth building food we have. We point out that the pinto beans they eat every day give them some bone and tooth

building material, but that if the expectant or nursing mother were to get all of the bone and tooth building food she needs (that is, the equivalent of that in one quart of milk), she would have to eat from nine to eleven cups of cooked pinto beans every day. It is not unusual for many of our families to have pinto beans for breakfast, dinner, and supper. We do not discourage this, because we have economic obstacles in obtaining the desired amount of milk. However, the idea that they should eat nine cups of cooked beans every day to get the necessary amount of bone and tooth building material appeals to their sense of humor. Even the bean lover sees the impossibility of consuming that many beans every day.

In our attempt to get more milk into the diet we can often find a native dish which can be used for this purpose. Atole is a traditional Spanish dish and one of the first foods given to the mother after delivery. It is a thin cornmeal gruel made from the blue cornmeal. It used to be made with milk, but nowadays it is more often made with water. We are encouraging the mothers and midwives to use milk again.

Another one of our nutritional problems is that of helping our families with a year-round food supply of vitamin C. Clinic examinations show that during the late winter and early spring months we have vitamin C deficiency. We have plenty of vitamin C foods in New Mexico and these foods are well liked by our families. Chili is an excellent source of vitamin C when fresh. During the summer it is eaten fresh, but most of the year it is used as a dried powder for flavoring. Many of our families are learning through the Extension Service, Vocational Home Economics, and the Farm Security Administration to can their chili and thereby have it as a source of vitamin C throughout the winter.

Cabbage is another favorite vitamin C food, but here our problem lies in teaching the newer methods of cooking vegetables without taking away the traditional flavor. It is usually cooked in large amounts of water for a long time, much as our grandmothers used to cook it. The cooking water is thrown away and then the cabbage is fried with onions and chili. It is questionable whether cabbage cooked in such a way has much food value by the time it is served. We are gradually teaching our families to cook the new way and to use the vegetable water. We suggest and demonstrate to them frying the onions and chili separately and then adding them to the cooked cabbage or other greens the same way we add butter to our vegetables.

THE NEED FOR DEMONSTRATION

Just to tell families these things is not the most effective way to teach nutrition. We need to show them. We need to develop visual materials which will emphasize teaching points. For instance, an x-ray picture showing the formation of the tooth in the infant's jaw does more to get the idea over that such growth takes place before birth than all the talking in the world. In giving explanations, vocabulary is very important. It is doubly important when the members of the class speak a different language from the teacher. All explanations should be in as non-technical language as possible.

SCOPE OF NUTRITION WORK IN NEW MEXICO

This year with two field nutritionists on the staff we hope to develop some nutrition classes for fathers. Many of our public health nurses have found that it is the father of the family, especially among the Spanish-Americans, who makes the decisions, holds the purse strings, and does most of the buying. It is essential in any family

teaching program to take the fathers into consideration. It is also necessary to work with that member of the family who really makes the decisions.

The nutritionist cannot give too much credit to the work of the public health nurses and doctors. They have preceded her in the field of public health by a good many years. By constantly rendering needed services to families and communities they have won acceptance for the whole public health program. This is probably the greatest single factor which helps the nutritionist in her public health efforts.

Nutritionists on the state staff can function most effectively by serving in an advisory or consultant capacity. The direct service given should have staff education as its main purpose. Where the family is concerned, the nurses of necessity have to do most of the nutrition teaching and only in so far as the specialist in nutrition is able to help the nurse apply the vast knowledge of nutrition in solving the nu-

tritional problems she meets daily in the field, can an effective nutrition education program in public health be built.

SUMMARY

Nutrition education is an important phase of the maternal and child health program. Its main objective is to improve the nutrition of every family and individual in the community. Since the number of nutritionists working in local health units is limited at this time, the responsibility of teaching nutrition to families falls upon the nurse. The nutrition consultant on the state staff then has the responsibility of helping each nurse in the state solve her local nutrition problems in a practical way. In New Mexico we feel that our nutrition work with the midwives has been an effective way of demonstrating nutrition teaching to the nurses. In this work particular attention was paid to the traditional food habits of the families served.

Stabilization of Chlorine in Water*

JOHN E. MILLER

State Department of Health, Lansing, Mich.

AND

W. L. MALLMANN, PH.D., F.A.P.H.A., AND
E. D. DEVEREUX, PH.D.

*Department of Bacteriology, Michigan State College,
East Lansing, Mich.*

IT is accepted practice to disinfect water with chlorine, using liquid chlorine, sodium hypochlorite, or calcium hypochlorite. It is generally believed that these various forms of chlorine give exactly the same results, the choice being a matter of convenience in application. The writers have been unable to find any information in the literature to the contrary.

The following case reports are presentations of observed sequences in the treatment of swimming pool waters with various forms of chlorine, or the application of the same form of chlorine to various types of water as it pertains to the hardness, alkalinity, and pH of the water.

Prior to the fall of 1931, the Michigan State College pool was supplied with a well water of 500 p.p.m. hardness and a pH of approximately 7.6. Disinfection was effected with liquid chlorine. Chlorine residuals of 0.3 to 0.5 p.p.m. were maintained. The pH of the pool water was approximately 7.6. The sanitary condition of the pool was excellent at all times. In the fall of 1931 the pool was supplied with Zeolite-softened water. After several weeks of operation the pH dropped to 5.5, chlorine residuals were zero, and the

pool water was badly contaminated. The pool was emptied and refilled with hard water. The pool operated satisfactorily, as it had previously with hard water. The hard water was continued and the problem was dismissed without further thought, and no further difficulty arose.

In the summer of 1940, when the Moore's Park outdoor pool in Lansing was opened for use, a lime-soda treated water was used and a similar experience resulted. This pool has a capacity of 225,000 gallons. The water is recirculated through pressure filters every 8 hours. Formerly a well water of 500 p.p.m. hardness was used. The pool was operated at a pH of 7.2 to 7.4, with a chlorine residual of 0.3 to 0.5 p.p.m. During the summer of 1939 6 to 8 lb. of liquid chlorine were used daily. Maximum bathing loads of 225 were maintained, with a daily load of 800 to 1,000 bathers. Only occasional slight difficulty was experienced in maintaining chlorine residuals of 0.3 to 0.5 p.p.m. with bright sunlight. In 1940 the city and pool were supplied with a lime-soda treated water with a hardness of 85 p.p.m. and a pH of 7.6 to 8.6. The pool was operated exactly as before except for the use of softened water. With bright sunlight the pH fell from 8.0 to a range of 5.5 to 3.5. All bacteriological samples showed a high total count and high colon indices. To

* Read at a Joint Session of the Laboratory and Engineering Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 15, 1942.

correct the pH, from 150 to 200 lb. of soda ash were added during the course of 2 weeks. During this period the pH would reach 7.1 at night but during the day it would fall to 5.5 despite the added alkali. It was impossible to maintain a chlorine residual in the sunlight. A heavy sludge formed on the bottom of the pool, apparently owing to the excessive use of soda ash. Following this experience, calcium hypochlorite was hand-fed into the pool for a period of 3 days. Chlorine residuals were maintained at 0.3 p.p.m. at the deep end of the pool during sunlight without difficulty. When the pool was again supplied with liquid chlorine it again became unsatisfactory.

Other soft water pools in the state were studied.

The outdoor pool at Midland is hexagonal in shape, with the inlet at the center at a depth of 10 ft. The flow is upward and outward to the edges, where the water flows continuously over a weir and through orifices. The pool has a capacity of 450,000 gal., with a 6 hour turnover and a 12 hour filter rate. The water is river water softened by a lime soda process. The softened water has a hardness of 80 to 85 p.p.m. and a pH of 8.6. At the opening of the 1940 season the chlorine fed was 15 to 20 lb. per day. The chlorine residual in the return line to the pool was 2 p.p.m., and 1 p.p.m. at the center at the surface of the pool directly above the inlet. The residual at the edge of the pool was 0. The pH was below 7.0. One to two inches of dead, burned magnesium oxide was placed on the filter as an experiment to increase and stabilize the pH. The pH increased from 0.2 to 0.4 but this increase was not sufficient to stabilize the chlorine or to raise the pH to the desired range.

Adjacent to this pool is a wading pool. This pool receives water from the larger pool. The overflow from the

wading pool is discharged to the sewers. Calcium hypochlorite is fed by hand in sufficient amounts to maintain 0.5 p.p.m. in the pool. No difficulties were experienced with this pool.

After observing the results of the hypochlorite in the wading pool and in the Moore's Park pool, 50 lb. of lime were placed in the mixing chamber of the large Midland pool. The pH increased to 8.0 or above and remained about 7.6 for several weeks without further addition of lime. The chlorine consumption was reduced by half and residuals of 0.2 to 0.5 p.p.m. were maintained at the edge of the pool in sunlight.

Following this experience, the Moore's Park pool at Lansing was treated with 15 to 20 lb. of lime during the course of 2 days. The pH was raised from 5.0 to 7.6. The chlorine consumption dropped from a maximum of 12 lb. to 6 lb. per day and chlorine residuals of 0.3 to 0.5 p.p.m. were maintained throughout the day. Bacteriological samples were satisfactory.

An indoor pool at the Roosevelt High School at Ypsilanti was next examined. This pool has a capacity of 60,000 gal. and is treated with liquid chlorine. The city water formerly had a hardness of approximately 350 p.p.m. and a pH of 7.6. The water is supplied from wells. When the pool was operated with hard water there was no difficulty in maintaining chlorine residuals or in maintaining the pH between 7.2 and 7.6. A small amount of soda ash was used occasionally for pH control following alum applications. About a year ago a softening plant was placed in operation. The softened water has a pH of approximately 8.6 and a hardness of 85 p.p.m. After using the softened water in the pool for a short period of time, the pH dropped below 7.0. At least 1 to 2 lb. of soda ash were required each day to maintain the pH in the alkaline range, generally at

pH 7. It was observed that the chlorine consumption increased materially and that it was virtually impossible to maintain chlorine residuals overnight without continuous operation of the chlorinator. Lime was substituted for soda ash for pH control. Approximately $\frac{1}{2}$ to 1 lb. a week was added to maintain a pH range of 7.2 to 7.6. A considerable reduction in chlorine consumption has occurred since the introduction of lime treatment.

Four indoor high school pools in Lansing were studied. These four pools had capacities of approximately 75,000 gal., with a filter rate of 8 hours. Bathing loads ranged from a minimum of 25 to a maximum of 40, the daily bathing load being 8 classes. Previous to the installation of electrolytic chlorinators, these pools were supplied with hard water of approximately 500 p.p.m. hardness from wells. Liquid chlorine was used for disinfectant. Chlorine consumption in all these pools averaged less than 1 lb. per day. No difficulty was experienced in maintaining a pH range of 7.2 to 7.6. No difficulty was experienced in maintaining chlorine residuals throughout the 24 hours of the day. Bacteriological samples were satisfactory.

In January, 1941, these pools were filled with a lime-soda treated water with a hardness of approximately 85 p.p.m. and a pH of 7.6 to 8.6. The pools were equipped at this time with electrolytic chlorinators, so the pools were being treated with sodium hypochlorite. During the first few weeks of operation, with relatively light bathing loads, it was impossible to maintain a satisfactory chlorine residual in any of these pools. The amount of chlorine used in each case per day varied from 2 to 3 lb. It was observed that, although sodium hydroxide produced by electrolytic chlorinators was being continually fed into these pools, the pH dropped from the initial pH of 7.8 to

7.2 which remained constant. A rise in pH would be expected, inasmuch as little or no alum was being used.

During this period of use, the pool water had a greenish-blue hue, sparkled, and bubbled. In the morning, after continuous chlorination throughout the night, tiny gas bubbles were breaking over the surface of the pool, particularly near the inlets. Prior to the entrance of the swimming classes the pool water was crystal clear, with the bottom plainly visible at the deep end. In a few minutes after the bathers entered the water, the water became very milky in appearance and it was impossible to see the tile or the joints of the tile in the shallow end of the pool at a depth of 3 ft. The agitation of the water by the bathers provided additional aeration and broke up the large gas bubbles into finer bubbles and produced a marked turbidity. When the bathers left the pool and the water was undisturbed, clarity was restored in a very few minutes.

Following these observations it was decided to apply lime treatment. Calcium hydroxide solution was applied at a slow rate to the recirculating system on the suction side of the pump, ahead of the filters and chlorinators. The average time of application was approximately $\frac{1}{2}$ hour per 1 lb of lime. After three applications of 1 lb. each, the pH of the pool water increased from 7.1 to 7.6 or slightly above. During the past several months of operation it has been necessary to apply from $\frac{1}{2}$ to 1 lb. of lime per week to maintain a pH of 7.6. Immediately following the initial introduction of the lime with the stabilization of the pH at 7.6, it was observed that the chlorine consumption per day was reduced by one-half.

The use of lime treatment has made it possible in these pools to maintain chlorine residuals at 0.3 to 0.6 p.p.m. and even higher without difficulty. It has been possible to hold residuals of

0.2 to 0.3 p.p.m. throughout the night without operating the chlorinators during this period, which had been impossible before lime treatment was used. The gas bubbles on the pool surface and the milky appearance during use disappeared when lime treatment was used. The color of the pool changed from a greenish hue to a distinct blue.

An outdoor pool, the Richmond Park pool at Grand Rapids, using softened water, was examined. This pool has a capacity of 1,000,000 gal. and a filter rate of 8 hours. Liquid chlorine is used for disinfection. The water is a softened river water with a hardness of 100 p.p.m. and a pH range of 9.0 to 10.0. The chlorine consumption in the pool averages between 15 and 20 lb. per day. This amount would be considered normal consumption for this size pool. No difficulty is experienced in maintaining chlorine residuals in bright sunlight. The stability of the chlorine in this pool as contrasted to the other pools cited in this paper is probably due to two factors—(1) the high pH, and (2) the relatively higher calcium and magnesium carbonate content of the soft water.

SUMMARY

This recital of case reports on swim-

ming pool chlorination shows that in Zeolite- or lime-soda-softened water the use of liquid chlorine or sodium hypochlorite is unsatisfactory, particularly in outdoor pools, unless chlorination is supplemented by lime treatment.

These data show that the addition of soda ash to adjust pH is unsatisfactory in chlorinated-softened water swimming pools.

These case reports indicate the apparent instability of chlorine in the form of liquid chlorine or sodium hypochlorite when introduced into a recirculation system where chlorination of the same water occurs and the depletion of the base is not controlled. A similar condition would likely occur in the chlorination of the water supply or a sewage effluent if the dosage of chlorine was in excess of the base necessary for the formation of hypochlorite and the maintenance of proper alkalinity for stabilization.

These case reports indicate a greater stability of calcium hypochlorite as compared with sodium hypochlorite.

A later paper will present the data obtained from additional observations and from laboratory studies on the stability of sodium and calcium hypochlorites and their relation to the chlorination of water supplies.

Decomposition of Land-fills*

ROLF ELIASSEN, Sc.D.

*Associate Professor of Sanitary Engineering, College of Engineering,
New York University, New York, N. Y.*

IN the past, there have been presented before the Engineering Section of the American Public Health Association papers describing the procedure of placing land-fills as practised by the New York City Department of Sanitation. In 1939, a report of the preliminary survey work on land-fills was presented by Carpenter and Setter.¹ It is the purpose of this paper to present more results of research on land-fill characteristics as carried out by the Work Projects Administration under the sponsorship of the Department of Sanitation and the technical supervision of the staff of the Sanitary Engineering Research Laboratory of New York University.

The investigations were made at the five locations described as follows:

1. *Baychester*—A marsh area of about 150 acres bounded by Baychester Avenue and Bartow Street and adjacent to Eastchester Creek in Bronx County. Fill operations were started about 1927 and approximately 80 acres have been reclaimed and are available for recreation centers, park areas, or public building sites.

2. *Canarsie*—A tract of about 25 acres lying at the southerly terminus of Remsen Avenue, Kings County, near Jamaica Bay. Field operations were started in November, 1935, and some 25 acres have been reclaimed.

3. *Fairfield*—An area of about 2,000

acres located at the southerly terminus of Pennsylvania Avenue, and adjacent to the southerly side of Fairfield and Flatlands Avenues in Kings County. This is near the head of a basin leading into Jamaica Bay. Filling operations were started in 1933 and approximately 100 acres have been reclaimed.

At the southerly end of the Fairfield land-fill a bridge approach has been constructed using land-fill material. This bridge is part of a grade crossing elimination at the junction of Pennsylvania Avenue and the new Belt Parkway.

4. *Floyd Bennett*—This tract of approximately 1,500 acres is situated north of the Floyd Bennett Airport and adjacent to and east of Flatbush Avenue. It lies near a basin leading into Jamaica Bay. Fill operations were started toward the end of 1936. The area reclaimed (approximately 350 acres) will be available for the extension of the airport.

5. *Riker's Island*—This is situated in Long Island Sound, midway between Hunts Point in the Bronx and North Beach in Queens. In 1900 the area of this island was approximately 30 acres; today it is approximately 425 acres. The Riker's Island penitentiary has been constructed on this site, and it may be used for other public buildings. Land-fill material which had been in place here for many years was used as fill for the field and runways at La Guardia Airport. After being trucked across a temporary wooden trestle to

* Read before the Engineering Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

the site of the airport, the consolidated land-fill material was compacted by trucks, bulldozed and rolled ready for paving.

In order to determine the composition of fresh land-fill material the contents of 168 refuse collection trucks were sorted, classified, weighed, and measured. The data were obtained from the examination of material emanating from 19 out of the 41 sanitation districts contributing to the land-fills in the Bronx, Brooklyn, and Queens.

The load of fresh fill material selected for analysis was dumped from the truck on a clear level area of the fill at one side of the normal dumping operations. The sorting crew would then segregate the baked goods, vegetables, citrus fruits, greens, meats, bones, fats, fish, paper, metal, wood, ashes, glass, leather, rags, grass and leaves, rubber, and the remaining miscellaneous items.

The different groups were then weighed on a platform scale and the data entered on the sorting and classifying form. These materials were then dumped to one side and pushed into the fill by a bulldozer. For purposes of tabulation and comparison the sorted

components will be considered in the following categories:

- A. Organic
 - 1. Food Refuse
 - 2. Paper
 - 3. Wood
 - 4. Miscellaneous, including rubber, rags, grass and leaves, leather, and other less prominent miscellaneous items.
- B. Inorganic
 - 1. Glass
 - 2. Metal
 - 3. Ashes

It is obvious that these components do not occur in the same ratios throughout the year. The greatest variation occurs in the ash component, since hard coal is the major fuel used for heating homes and buildings in New York City. Therefore, the analyses were made each month and are summarized in Table 1.

It will be noted that the principal variations occur in the percentage of food refuse and ashes. These results should not be confused with the total tonnage of refuse received at the fills each month. They signify only that of all the refuse, with total tonnage varying each month, the percentage of each of the segregated items follows the variation shown in Figure 1.

BASED ON 168 TRUCK SAMPLES

TABLE 1

*Monthly Distribution by Weight of Fill Material
Based on the Sorting and Classifying of 168 Truck-loads of Fresh Fill Material*

Month	Organic				Inorganic			Total	Total Organic	Total Inorganic
	Food Refuse	Misc.	Paper	Wood	Metal	Glass	Ashes			
	%	%	%	%	%	%	%	%	%	%
January	5.7	1.0	12.4	0.3	4.3	4.0	72.3	100.0	19.4	80.6
February	9.0	1.7	12.6	0.7	6.6	4.9	64.5	100.0	24.0	76.0
March	9.7	2.1	20.6	0.3	7.4	7.3	52.6	100.0	32.7	67.3
April *	18.1	2.8	21.6	2.0	7.4	6.9	41.2	100.0	44.5	55.5
May *	26.7	3.3	23.0	3.1	7.1	6.8	30.0	100.0	56.1	43.9
June *	35.1	3.8	24.3	4.6	6.4	6.8	19.0	100.0	67.8	32.2
July	43.8	4.1	25.5	5.9	6.6	6.3	7.8	100.0	79.3	20.7
August	23.1	7.4	37.6	3.8	11.6	5.1	11.4	100.0	71.9	28.1
September	12.6	5.6	26.7	4.9	8.2	9.1	32.9	100.0	49.8	50.2
October	10.1	3.8	31.0	2.6	8.9	4.0	39.6	100.0	47.5	52.5
November	6.6	1.9	18.0	2.1	3.8	2.9	64.7	100.0	28.6	71.4
December	3.5	0.8	9.0	0.8	3.1	1.9	80.9	100.0	14.1	85.9

* No samples taken in April, May, or June; obtained by graphical projection.

The material actually entering the fill does not include all of the components noted above. Contractors purchase scavenging permits from the city for the privilege of reclaiming such items as stoves, hot water tanks, large tin cans, and other metalware of value, rags, paper, tires, and any other material which can be sold to dealers. The amount of recovered material depends on the market value of the recovered waste and other factors in the economic cycle. Therefore, adjustments in the percentages entering the fills must be made to account for scavenging operations.

Having analyzed the fresh fill mate-

rial, it was desirable to take samples of land-fill after it had been in place for different periods of time. Sampling was accomplished by means of auger type post hole diggers which could be operated to a depth of 25 feet. Four auger holes were dug at the corners of a 100 foot square located in the center of the area to be sampled as shown in Figure 2. Three samples representing the top, middle and bottom of each hole were obtained. After quartering and collection of composite sample, the material was dried, manually separated and screened into the following classifications: material retained on 4 mesh screen, material pass-

SAMPLING LAYOUT & PROCEDURES

Sampling Procedures

A—Fill Material

1. Material sampled at each level from each of the sampling points, A, B, C & D is brought together on a clean tarpaulin.
2. It is then thoroughly mixed (composited).
3. The sample is reduced by quartering to one gallon.
4. The sample is placed in a one gallon friction top can, and submitted to the laboratory for analysis.
5. Report of field sampling data is made and forwarded to the laboratory with each sample.

B—Gas Sampling

1. At point of sampling (G) a gas sampler is driven to the sampling depth.
2. A sample of gas is taken from the fill.
3. The sample of gas is analyzed and data are entered on the gas analysis form.

ing 4 mesh and retained on 14 mesh screen, and material passing 14 mesh screen.

It was found that an average of approximately 30 per cent of the total material in the fills ranging from 3 to 120 months in age was large enough to be retained on a 4 mesh screen, the greatest portion of this being mineral matter. Approximately 20 per cent of the total passed the 4 mesh and was

retained on the 14 mesh screen, most of which was ashes. The remaining 50 per cent passed the 14 mesh screen and was partially disintegrated and unrecognizable organic matter. Most of the analyses hereinafter mentioned were made on the material passing the 14 mesh screen.

One of the principal elements of organic compounds being carbon, it was found advisable to obtain an indica-

tion of the organic carbon present in land-fills. After trying several methods, the one involving the 2 hour digestion of organic matter using an excess of 50 per cent chromic acid at room temperature, was found to give the best indication of the oxidizable matter present. The results of analyses of the residue passing the 14 mesh screen are shown in Table 2. It will be noted that there is an appreciable reduction in the per cent of oxidizable matter after four years of decomposition in the land-fill. It is difficult to explain the reason for an increase in this matter with depth, except that it must be a characteristic of the placing operations, as the analyses show a consistent increase with depth.

Organic nitrogen is a criterion of protein derivatives present in land-fill material. The results of analyses are given in Table 3. It will be noted that decomposition over a period of four years does not bring about any great reduction in the amount of organic nitrogen present.

The environmental conditions are extremely important in any organic reactions brought about by bacteria and other microscopic organisms. First among these is the pH of the solution in which these organisms act. Table 4 presents the results of analyses of land-fill samples of various ages. It will be noted that the range of pH is from 5.3 to 8.5, with a mean close to the neutral point. This would indicate that the

material is well buffered and provides a favorable environment for bacterial metabolism.

It is interesting to note the number of organisms in the land-fill which will appear on a total plate count at 37° C. This is indicated in Table 5. The trend is obviously toward fewer organisms as the decomposition proceeds and the available organic matter becomes depleted. These large numbers growing on nutrient agar do not begin to show the total number of organisms actually present and taking part in the complex processes involved in the breakdown of organic matter.

Since land-fill material is not of a fecal nature, it therefore should not be high in organisms derived from the in-

testinal tract, such as would be the case with sewage. Analyses of land-fill were made for *Escherichia coli* organisms and the incidence of these is relatively low, as indicated in Table 6. It is obvious that these are not the essential organisms in the decomposition of land-fills.

Fungi are present in much of the food refuse disposed of as garbage and then deposited in land-fills. The numbers of these organisms in each gram of dry fill are of astronomical proportions, as shown in Table 7. The same is true of actinomyces. Both of these groups of organisms are highly active and responsible for much of the breakdown and consequent stabilization of land-fills.

Although the fills may be placed dur-

ing the coldest of weather, the material is insulating in character, so that heat is not readily transmitted to the atmosphere. The reactions are thermogenic in nature and bring the temperature of the material to the values shown in Figure 3. These are in the range between the optimum temperatures for mesophilic and thermophilic organisms. Investigations have shown that both types are present and assist in the decomposition.

One of the principal characteristics of land-fills is the dryness of the material

as placed. The large amount of paper and ashes more than counteracts any moisture derived from the food refuse and other moist materials. The moisture content of land-fill material of various ages and at different depths is shown in Table 8. It will be noted that the moisture increases with age and also with depth. These observations are logical because the infiltration of surface rain water will tend to accumulate in the dry material. Furthermore, water will naturally gravitate downward in time. Moisture bears a

definite relation to bacterial efficiency, as these and other organisms require the presence of water for survival and reproduction.

Studies were carried out to determine the optimum moisture content of land-fill material in an attempt to correlate existing conditions with those deemed

theoretically optimum. The procedure involved comminuting 5 grams of dried land-fill and placing it in a Petri dish with the proper seed of organisms and the necessary water to make up to a given percentage moisture. Decomposition took place at a constant temperature and under aerobic conditions. The criterion of biochemical activity was the amount of carbon dioxide gas produced in a given time. All of the CO_2 was dissolved in a solution of sodium hydroxide which could be titrated before and after the experiment to determine the consumption of NaOH by the CO_2 . The results of this work are indicated in Figure 4.

These results indicate that for the fresh land-fill material the optimum moisture content lies between 50 and 70 per cent. For older fills the optimum region expands to include values between 30 and 80 per cent. As shown in Table 8, the moisture content of land-fills averages between 20 and 30 per cent and this does not approach the optimum values. These results would further indicate that more rapid decomposition of land-fill could be obtained if additional moisture were added to the fill while being placed. This could be accomplished by having streams from a fire hose play on the material as it is dumped from each truck. Experiments of this type have

been planned and the results will be watched with interest.

Under actual field conditions the air in the fills is rapidly exhausted and the process of decomposition becomes anaerobic. This is evidenced by the results of many gas analyses taken from within the land-fill. The constituents varied considerably but the indications were that the gases averaged 30 per cent carbon dioxide, 45 per cent methane, 3 per cent oxygen, 0.1 per cent hydrogen, and the remaining 22 per cent nitrogen and other inert gases. The high percentage of methane and almost complete absence of oxygen serves to indicate the anaerobic character of the decomposition.

The ultimate object of the decomposition of land-fill is the stabilization of the material so that the ground above may be used for recreational or functional purposes. Further investigation is necessary to correlate the data already collected on settlement of the fills, permissible bearing loads and other factors of an engineering nature. The material presented in this paper should serve to indicate the nature and extent of the biochemical reactions which take place during the decomposition of land-fills.

HOUSING OF HEALTH DEPARTMENTS

IN the May 22 issue of *Public Health Reports*, the *Housing of Health Departments* was discussed by Assistant Surgeon General Joseph W. Mountin of the United States Public Health Service; and in the July number of the *Architectural Record*,* the Hospital Facilities Section of the United States Public Health Service made available its *Study of Health Centers*.

In the first of these articles, health department housing, as it is, comes in for severe criticism. The situation is analyzed as to cause or causes, and brief but definite suggestions are made as to remedies. The Study, with a foreword by Dr. Parran and an introduction by Dr. Mountin, provides floor layouts for health centers designed to serve populations up to thirty thousand, sixty thousand, and one hundred thousand respectively. Supplementary data are provided as to office and clinic equipment, clinic loads, and even clinic schedules are suggested. One might, with reason, feel that there is a bit too much minuteness in some of this, perhaps more certainty in detail than is justified, but it is a valuable document and one to be studied and acted upon.

Of equal importance with the recommendations made in this study, probably of more importance, is the necessity for eradication of that attitude in health officers, public officials, and the public generally, which in the past has inhibited the provision of decent housing of health departments; and there must be developed, too, a state of mind which will insure proper quarters in the future. In retrospect one may see quite clearly that no small part of the present unsatisfactory situation arose because the launching of full-time local health service has always been an up-hill fight. The state health officer promoting such service has been forced to make compromises of all sorts in order to get a toe-hold for local service. He has had to approach the whole problem with over-emphasis on how little it would cost the community; he has occupied the rôle of supplicant and seldom has he been in position to lay down minimal requirements as to anything, to say nothing of health department quarters. And the

* Copies are available upon request from the A.P.H.A. office.

local health officer, in accepting, selecting, or equipping quarters, has had to be somewhat careful lest, to the jeopardy of his whole program, he label his work as foreign, by failure to acquiesce in the shirt-sleeve and tobacco-spitting type of local administration seen in most small units of government.

Perhaps there has been justification in the acceptance of expedients and compromises in health department quarters. It may be that if this had not been done many communities which now enjoy health service of a sort would not be as well off as they are. As against this, though, is the ever-present danger that compromise measures tend to freeze into permanent practices; that a tuberculosis service, at first maintained on a high plane in spite of all difficulties, may sink to the level of inadequate facilities; that the insanitary condition of health department quarters as a whole and the unpleasant odors of the venereal disease clinic, in particular, at first distressing to doctor and nurse alike, are sooner or later accepted through dulling of the sensibilities. That this is what ordinarily happens, there can be no doubt; and the correction of it will be brought about only by strong, concerted, and continuing action and assistance under federal, state, and foundation leadership.

On the positive side, separate, and distinctive, quarters have much to commend them. Aside from providing an opportunity for more nearly adequate and better work, the presence of a dignified and inviting health center has an important bearing upon the amount and kind of use which the community will make of the health services, and the regard in which the public holds the health department. It may not be logical, and from the standpoint of clear thinking perhaps it should be deprecated, but the fact remains that the public is not inspired by the light under the bushel, nor is John Citizen impressed by something he cannot see. He wants concreteness, an emblem, a symbol. He appreciates length, breadth, and thickness more than he does an abstraction. Thus, in an association-of-ideas test, to the word "education" he would probably respond with "school"; to "religion" his reply would perhaps be "church"; and to "United States Mail" he would in all likelihood say "post-office": all these responses represent three dimensional concepts, in terms of buildings. What would be the response today if to the average small town citizen one suddenly said "health department"? Perhaps there would be no association, or possibly it would be "basement" or "dingy" or "the old school house." As a remedy for this we need to bring about such an attitude on the part of the public that in an association-test situation, the person tested will upset the procedure; that the mere voicing of the term "health department" will arouse him sharply from the semi-lethargy necessary for free association, and he will with alertness and interest and enthusiasm exclaim: "Oh, you mean that spick and span Health Center, where such excellent service is rendered, and which is by far the best investment we ever made." Only we hope he will say it less pedantically.

THE SULFA DRUGS AS PRODUCERS OF EMOTION

ONE can understand why emotions flash when a subject such as socialized medicine is introduced into a discussion. In such circumstances it is more than likely that the discussers visualize themselves as parties at interest or in jeopardy, or that one arguer has a low opinion of someone who is in favor of

socialized medicine and another has a low opinion of someone who is against it, or very much vice versa.

It is natural that in a situation of this sort emotions rather than logic influence both the pros and cons and, because the problem is more closely related to sociology than to science, the approach is philosophical rather than scientific. But it is a little difficult to appreciate the psychological reaction of those who become red faced and vehement in discussing the efficacy or lack of efficacy and the dangers or lack of dangers of a therapeutic agent, such as the sulfa drugs. On the one hand is found the practitioner who has less fear of such a drug than of aspirin; who advises and prescribes it for anything and everything, who in no way checks upon the reactions to the drug, and considers that he has wrought a cure unless he has to sign a death certificate. With an experience of this sort behind him, this physician is prepared to take on any colleague who has the temerity to argue against the soundness of his procedure and the magic of the drug. As opposed to him, and certainly someone should oppose him, is the individual who reacts unfavorably to almost anything that is new, who is an avid collector of records of untoward results in sulfa-drug therapy, and who, tending to forget all benefits that have accrued, roundly denounces this new chemotherapy as an invention of the devil.

Perhaps it is in discussions of the treatment of gonorrhea with sulfa drugs that one encounters the most vehement arguments. Enthusiasts will imply a desire to place packets of sulfa drug tablets in slot machines and let whoever has gonorrhea and twenty-five cents try his luck. Others, at the mere suggestion of sulfa drug efficacy in shortening and curing the disease, become so incensed that they charge the drug with "creating" gonorrhea carriers. Few informed persons would be prepared to acquiesce in either of these extreme views. Which is the more nearly correct is not here the issue. The point to be emphasized is that the true place of the sulfa drugs in general and especially in relation to gonorrhea will be reached much more quickly through an objective approach and a minute sifting of evidence than through emotional support of a prejudice in either direction.

WHAT AND WHO IS AN EPIDEMIOLOGIST?

Comments on an editorial published in the April, 1942, issue of the JOURNAL

From one of the Old Masters, L. L. Lumsden, M.D., Medical Director (Ret.), U. S. Public Health Service, New Orleans, La., comes this analysis:

Definitions are always difficult and often unsatisfactory, with one just calling for another. However, the editorial in the April, 1942, issue of the JOURNAL on "What and Who Is an Epidemiologist?" is to us, who for some time have been striving to earn the title, provocative and even challenging. Furthermore, the defining of epidemiologist is no more nor less difficult than is the defining of physiologist or pathologist. The writer of the editorial evidently realizing the difficulty of satisfactory

defining, gives an "assist" by asking a number of questions, the invited answers to which might serve to furnish a definition by a sort of process of elimination. So here goes at the answers:

- Q. "Are epidemiologists born or made or just self-confessed?"
- A. They must be both born and made. Being just self-confessed is not enough.
- Q. "May the clinician, the statistician, the bacteriologist properly designate himself as an epidemiologist?"
- A. No; but any of them, notwithstanding or even in spite of his former predilections,

may become an epidemiologist by proper application and by having what it takes.

Q. "Can one be an epidemiologist and something else besides?"

A. Yes. Outstanding in the all-time list of epidemiologists have been Pasteur, a chemist, Jenner, Budd, and Snow, practising physicians, and Sedgwick, an engineer.

Q. "Does the first-hand experience of a quarantine officer take him within the fold?"

A. No.

Q. "What about one who, in retrospect, studies the data of past epidemics; and the medical historian with intimate and detailed knowledge of the classic writings in epidemiology?"

A. They may be regarded as academic but not as practical epidemiologists or going concerns.

Q. "One who concentrates upon a single disease—its laboratory, clinical and epidemiological aspects—is he an epidemiologist in general or only in particular?"

A. He may be both. If Reed and Goldberger had done no epidemiological work except what they, respectively, did on yellow fever and pellagra, they would have held high rank as epidemiologists.

Q. "May one not formerly an epidemiologist reach this state merely by being given responsibility for epidemiological work?"

A. No; in years past, we have seen, off the job, enough of this sort to make us sure.

Q. "If once an epidemiologist is one always an epidemiologist?"

A. No; some of them become lunatics.

Q. "Is epidemiology a status that may be conferred by acclamation or announcement?"

A. Perhaps under some circumstances, but as a rule only for purposes of sociability.

Q. "Does portentousness of manner and mien tend to cause colleagues to accept one as an epidemiologist?"

A. Yes, at times, but it never should.

Now, having got this far along, here goes at home-made definitions of "What and Who."

What?

An epidemiologist is one who is importantly concerned with or essentially engaged in broad-gauge and intense studies, including field observations, of conditions known or reasonably supposed to influence the occurrence of

disease. Who says "importantly," "essentially" and "reasonably"? The epidemiologist himself does, and who shall say him nay?

This leads to

Who?

One who does well enough epidemiological work to deserve recognition.

Recognition from Whom?

Answers to that would vary much according to the audience interrogated. For convenience, we may start off with the judgment of those who from study, training, and experience have technical knowledge of epidemiological procedure and end up with the common opinion of mankind. A detective who solves a murder mystery and an epidemiologist who solves an important disease-causation problem usually obtain favorable popular recognition. But some of the highest grade epidemiological work does not result immediately in an important discovery, but builds up, step by step, a structure of facts by which eventually someone else may climb to the light.

No standard of qualifications for an epidemiologist has been set up by authority. Therefore, the decision as to who in our midst is an epidemiologist is wide open. He should be judged by his works. Among some of the distinguishing features which are helpful in the establishment of his identity are the following:

1. He has in his makeup two essential elements—common sense and the will to work.

2. He applies his common sense in formulating his program of studies and in interpreting and presenting his findings.

3. To him facts are all important. He goes after them and gets them, and in collecting them he is diligent, patient, careful, thorough and unbiased.

4. He endeavors to put together the facts so as to make a simple, readily readable picture.

5. In his presentation of findings, he avoids needless or obfuscating high mathematics and formulae.

6. He bases his conclusions on the factual evidence and he does not twist the facts to try to make them appear to conform to some favored previous concepts of himself or others.

7. He remains broad-minded and open-minded throughout his procedures.

8. He is humble in his ignorance but bold in his search for truth.

9. His doctrine is that of Montaigne's ancient sailor who in the midst of a great storm said to Neptune: "O God, thou shalt save me if thou please, if not thou shalt lose me; yet will I keep my rudder true."

Joseph C. Willett, D.V.M., Chief of Laboratories, City of St. Louis, comments as follows:

In view of what has been said, as well as some of the omissions concerning epidemiologists, may I venture that an epidemiologist is one who by virtue of training, experience, and actual demonstration, is capable of recognizing, investigating, and appraising all of the circumstances (obvious and otherwise) connected with the occurrence of disease in man or animal and consequently discovering the essential basic factors (source, etiology, distribution, incubation, etc.) necessary to disease control and prevention.

As in other fields of endeavor, we must recognize the capabilities of different epidemiologists—if we were to define "detective" as a person capable of recognizing and investigating all the circumstances connected with crime, we would still distinguish between the arm-chair Sherlock Holmes and an accomplished operative of the FBI.

Yes, even grandma, who recognized

all of the diseases of childhood and perhaps knew something about the "circumstances connected with their occurrence," was an epidemiologist, as was grandpa, who possibly knew a lot about hog cholera. However, in modern preventive medicine our epidemiologists must have better basic training—yes, even better than that afforded by the present medical or veterinary schools.

The bacteriologist, clinician, statistician, of which you speak may be epidemiologists with the same degree of success as the average intelligent non-arthritic layman attains in forecasting the weather.

Possibly we could better appraise the practical worth of our epidemiologist if we looked to the thickness of the callouses on his feet, and the number of successful epidemic investigations to his credit, as well as to the kind and number of letters after his signature.

C. E. Dolman, Ph.D., D.P.H., Professor of Bacteriology, University of British Columbia, Vancouver, B. C., sends this letter:

When I asked the above question of three colleagues, they replied respectively: "a transportation expert," "a contact tracer," and "a totipotential sleuth." The expertness my first colleague (a bacteriologist but no cynic) had in mind related to the tracing of the most likely route for a given pathogen to have travelled, rather than to the working out of the most expen-

sive way for an epidemiologist to have made a given trip. The second colleague was a venereologist, and so may be excused for his definition. The third had been an epidemiologist too recently for all bitterness to have mellowed. Although there seems nothing essentially wrong with any of their replies, the most satisfactory definition of an epidemiologist is surely the simplest and

most literal, that he is a person who looks into, deals with, knows about, and treats of epidemics.

But I should judge that this dissection by correspondence of the epidemiologist was initiated not so much to determine more accurately his structure and functions, as to help define his status and strengthen his hand. The junior epidemiologist's lost look, and the senior's "portentousness of manner and mien," are not altogether their fault. Any of us might well feel baffled if, knowing our job was to look into epidemics, we were apt to find ourselves on the scene too late to make a first-class investigation, and were met on arrival with conflicting answers to almost every question; if, in attempting to deal with the epidemic, we were often balked by lack of clear-cut authority; if, in trying to persuade at least ourselves that we knew about epidemics, our self-esteem was sometimes shattered through the specimens we had assiduously collected being mocked at or spurned by the laboratory, and through our carefully illustrated itinerary being consigned, without praise or blame, to some dark file in a central

office; and especially if, in an endeavor to "treat of" some epidemic publication of our findings was banned because of feared legislative complications.

Such difficulties as these do not refute, but only emphasize, the need for more and better epidemiologists. Together with his public health laboratory colleague, the epidemiologist furnishes most of the information on which any sound health department program is founded. Yet these persons seldom occupy the honored place in the departmental hierarchy to which their objectives and training entitle them. What they lack is not responsibilities, but prestige; and this cannot lean on tradition, even when, from Fracastoro to Snow, from van Leeuwenhoek to Pasteur, the tradition has been compounded of integrity, scholarship, courage, and leadership. But these very attributes are still recognizable enough to bring prestige to those who manifest them. When this is fully realized, and the epidemiologist, turning to his laboratory colleague, grows in every sense attached to him, they will wax strong together, to their own and their community's lasting benefit.

This discussion will be brought to a close in the November issue.—EDITOR

A Selective Digest of Diversified Health Interests

D. B. ARMSTRONG, M.D., AND JOHN LENTZ, M.S.

REAL HEALTH EDUCATION

The Scene: A county health department.

Characters: A health officer, a mother, and a nurse.

[Enter, the nurse]

Nurse: "Doctor, Mrs. Cook is here to see you. She insists on talking with you personally, although I suggested that she might see some other doctor on the staff. She only wants to know about taking the Pasteur treatment."

The Health Officer: "I should be at the immunization clinic now. Perhaps it won't take long—send her in."

[Mrs. Cook enters accompanied by the nurse. It is evident from her expression and actions that she is disturbed and anxious.]

The Health Officer: "I'm glad you've come to the health department, Mrs. Cook. I believe you've never paid us a visit before. I know your community pretty well—seems we should have met long before this."

Mrs. Cook: "I feel that I know you already, Doctor. I've heard the children speak of you and I've read in the papers about the work you are doing here."

The Health Officer: "The nurse tells me that you want to inquire about the Pasteur treatment. Now, just what is your question?"

Mrs. Cook: "My 12 year old son agreed to tend the cows of our nearest neighbors while they were away on a short vacation. One of the cows acted queerly and my son tried to find out what her trouble was. He knows how to care for livestock, and in attempting to give the cow some medicine, he got a nip on the hand. Finally, a veterinarian was called and he said the cow had rabies. By the time we got the animal's head to the laboratory, the doctor there said he could not make the tests to tell whether or not the animal was actually mad as the head was too far decomposed."

The Health Officer: "Yes, that often happens. The head must be well preserved or the laboratory man will be unable to locate certain characteristic structures that show up in the brains of animals that have rabies."

Mrs. Cook: "And that's just why I'm so disturbed, Doctor—not knowing whether or not my boy is in danger. I know that rabies is fatal once it develops and of course I want him protected if there is the slightest chance that he might have it. But I'm also afraid of those 'shots'—I've heard they are dangerous, that they don't always work, and that the injections cost a lot."

At this point the health officer might have made a few statements urging the mother to have her son protected, regardless of what she had heard about the "shots." But here was a woman

Please address samples of printed matter, comments, or other editorial contributions to the editors at One Madison Avenue, New York, N. Y.

who had never been to the health department before—and thus there was an opportunity at hand to make another advocate of public health, another opportunity to impart health education. Thereupon, the health officer called for his records. He cited the number of Pasteur treatments given in his department over a period of years, he told how the injections were administered, he pointed to the various age groups that had been treated, and he emphasized the generally successful results and the lack of complications arising from the administration of the vaccine. He might have stopped there, but there was still other evidence to reassure this mother.

[Turning to his bookcase, the health officer drew from its shelves a well known textbook on public health and hygiene.]

The Health Officer: "Mrs. Cook, perhaps our experience here does not clear up all your doubts about the value of this treatment. Well, here's a textbook that every public health man in the country looks upon as a sort of Bible of the profession. Let's see what the author has to say about the Pasteur treatment."

[And thereupon the health officer read aloud to Mrs. Cook sections of the chapter on rabies that would help to dispel her anxiety. She listened attentively as the health officer read and translated the author's phraseology into simple, readily comprehended terms. An observer could see this mother's doubts and fears and uneasiness vanish as steam is wont to vanish into thin air.]

Mrs. Cook took leave of the health officer reassured, composed, and grateful. She might have left under far different circumstances had not a busy, harassed, sympathetic health officer

taken time to give her facts and figures as to his own experience and that of others regarding the efficacy of the Pasteur treatment. Perhaps he was late at the immunization clinic, but what better evidence could be offered that his time had been well spent than Mrs. Cook's parting remark: "Now I understand, Doctor. I'll have my son here in the morning to begin those 'shots' regardless of what they cost. I'm going to tell him what you've said—and neither he nor I will be afraid!"

This, it strikes us, is health education at its best and proof that the health officer can be the most effective of all health educators.

AN EDITORIALETTE:

HEALTH IN WARTIME FOR THE "UNDER SIXES"

Herewith we present our second guest editorialette, submitted in response to invitations extended in these columns during recent months. Miss Marjorie L. Craig, of the School Health Bureau, Welfare Division, Metropolitan Life Insurance Company, has written the following:

The importance of the young child's health has long been stressed by leaders in public health through their excellent programs on maternal and infancy care, including diphtheria immunization and vaccination against smallpox. The public health profession is now being called upon to give more attention to all the "under sixes." Many problems of the preschool child have been accentuated by war conditions, and action has become more urgent. Housing facilities, particularly in industrial areas, are inadequate, sanitary conditions are unsuitable, and the possibilities of contagion and poor general health are amplified. The war has brought about new fears and insecurities and has created fewer opportunities for good emotional hygiene and social growth. The health of some 10 million "under

sixes" has real significance in the war program. Military and industrial men and women must have faith in the security of their children before they can give their most efficient service. New emphasis is being placed on providing for children the best possible kind of physical, mental, emotional, and social environment which is basic to a nation's security in any era.

Charles Schottland, formerly of the Children's Bureau, has been appointed to the Office of Defense, Health, and Welfare to coördinate the services for children offered by health, welfare, and educational agencies. All over the country, organizational interest is being submerged and is giving way to the wholesome development of the individual child as uppermost in the minds of those responsible. New programs for young children are springing up rapidly and it is hoped that the public health profession will coöperate in making available health facilities consistent with accepted standards. Nursery schools, day nurseries, child care centers, and other services are essential if today's children and the children of the future are to have opportunities for American life and the liberties for which we fight on every front.

(EDITORIAL NOTE: These columns are still open to other contributors. Please let us have your comments on any subject—preferably with a health education slant. While we cannot guarantee publication, serious consideration will be given to all material submitted.)

NOTES ON PUBLICATIONS

You will want to see:

Record of Service, 1940-1941, the biennium report of Memorial Hospital for the Treatment of Cancer and Allied Diseases, 444 East 68th Street, New York, N. Y.

"The annual report of a hospital

should provide more than an accounting of the expenditures of funds and a recounting of routine activities. The statement should convey to the reader the spirit which animates the institution, the ideals to which its personnel aspires, and the ends which they wish, and presumably expect, to attain."

Upon this premise, Memorial Hospital has based its latest report. That it reflects in a most admirable manner the spirit, the ideals, and the scientific and humanitarian principles underlying the work of this great institution is but faint praise for such an excellent summary. The text, for the most part, is devoted to the promising research studies which the institution is pursuing "to ferret out the cause of the mysterious, malignant disease which we call cancer and detest as such." One finds in the pages of this report many hopeful developments looking to the control of this disease, particularly as regards the more recent chemical and nutritional approaches to the problem. Of especial interest also is a section of the report dealing with the social and economic aspects of cancer. The institution recognizes that one of its chief tasks is "to bind up the mental, social, and economic wounds of those devastated by this disease." We know of no current statement, either of a popular or scientific character, that so succinctly analyzes and appraises current efforts and future possibilities in the field of cancer research. The report has other features of note including an attractive cover depicting, by means of a photo-montage, various functions of the hospital. The report is also well executed typographically.

(In connection with the report of Memorial Hospital, we wish to air one of our pet "causes." This publication, like so many others in the medical and public health fields, employs as a title page decoration, the caduceus. While the symbol of the staff, the intertwined

serpents, and the pair of wings is commonly used to represent the healing art, it is not the *true* symbol of the profession. The authentic symbol of medicine is composed of the knotted staff of Aesculapius, the divine healer, wound with a single serpent. It appears in a very few publications. The precedent for using the caduceus, rather than the staff of Aesculapius, goes back to Johann Froben, a Swiss medical printer who lived several hundred years ago. Froben, with an eye for symmetry, preferred the caduceus to the less decorative Aesculapian staff—and thus it came into use as Froben's books were widely circulated among medical men. If authenticity is the quality for which we strive in health and medical publications, why should this not apply even to devices used purely for decorative "touches"? Down with the caduceus! Up with the staff of Aesculapius!)

The Well-Filled Dinner Pail, a folder published by the Iowa State Department of Health, Des Moines, Ia. Single copies offered without cost.

Today, more than ever before, housewives are faced with that perplexing question: "What can I prepare for my husband's lunch that will please him and keep him fit for the job?" Generally, the worker's lunch has lacked variety and appetite appeal. Thanks to the Iowa State Department of Health, suggestions have now been set forth that will make any man look forward to the lunch hour. In this publication, complete menus are outlined for every working day—each menu being planned to supply the body's mechanism with "high octane gas" for the vital jobs that are being done. There are also suggestions in this folder for the preparation of "hearty sandwiches," with a wide variety of unusually tempting and nutritious fillings. Tips are also given concerning hot and cold drinks, raw and cooked fruits and

vegetables, and desserts. This timely and practical publication should be had by every housewife who faces the daily chore of preparing lunches for working men. The folder is neatly printed in red and blue and the text is conveniently arranged for ready reference.

Good Teeth, a publication issued by the Metropolitan Life Insurance Company, 1 Madison Avenue, New York, N. Y. Available without cost.

Current interest in dental health, stimulated to a large extent by the number of draftees who were pronounced dentally unfit, has made the need for educational materials in this field more urgent than ever. Accordingly, the Metropolitan has revised its booklet on the teeth with the coöperation of the American Dental Association in order that the most authoritative information on the more important and practical phases of dental health might be made available to the public. The text is simply written and a variety of charts, illustrations, and diagrams are included to emphasize some of the more important aspects of the care of the teeth.

Diphtheria and Smallpox Can Be Prevented, two leaflets issued by the Kansas State Board of Health, Topeka, Kans. Available without cost.

Here are two publications notable for their brief, explicit, informative content. Although they lack illustrations and fancy art work, these leaflets win attention readily as bright colors are liberally used on the covers. Each leaflet also contains quotations from what is presumably the Sanitary Code of Kansas, citing the law with respect to reporting, placarding, quarantining, and the like, in cases of diphtheria and smallpox. This is a somewhat unusual feature—one which we have not seen embodied in popular health education materials heretofore, and perhaps of

special interest to physicians. Since few laymen and not all doctors are familiar with legal provisions of this nature, it seems that other states might well use the same medium to publicize their legal safeguards regarding communicable diseases.

Hartford Health Bulletin, a monthly periodical published by the Hartford Board of Health, Hartford, Conn. Copies available on request.

This bulletin, which is simply and economically produced, is at the same time highly interesting chiefly because it is prepared by someone with a keen sense of news values. The issue at hand, for instance, features several stories in which current health activities are "played up" in relation to the war effort. On the cover, a "Victory Health Program" is outlined in a rather ingenious layout consisting of a large V in which the following essentials are printed: outdoor exercise, varied food, restful sleep, frequent health examinations, vaccination, immunization, child care, sanitary homes, personal hygiene, hard work, community interests, early medical care, and regular dental care. This bulletin also carries an excellent statement in which the practical aspects of the nutrition program, especially as applied to war workers, are emphasized. If there is any health officer who can speak with first-hand knowledge on this subject it is the health officer of Hartford as his community is the center of a vast amount of our industrial effort. Dr. Alfred L. Burgdorf, the Hartford Health Officer, and his associates may well be proud of the bulletin which they issue.

CONCERNING POSTERS AND EXHIBITS

One of the country's leading advertising agencies, Young and Rubicam, Inc., recently completed a study of war posters that have been exhibited in

Canada during the past two years. The purpose of this study was to determine the type of poster that has been most successful in mobilizing the Canadian people in support of the war effort. It was felt that such a study might produce knowledge that would aid materially in the production of effective war posters by our government. Health educators will find many of the conclusions interesting and perhaps valuable as "pointers" that should be considered in the preparation of health posters.

Among the conclusions reached are: (1) The most effective war posters appeal to the emotions. No matter how beautiful the art work, how striking the colors, how clever the idea, unless a war poster appeals to a basic human emotion in both picture and text, it is not likely to make a deep impression. (2) The poster should be a picture, not an all-type poster or a symbolic design. And by a picture is meant a true and literal representation, in photographic detail (though not necessarily a photograph) of people and objects as they are, and as they look to the millions of average people. If it isn't such a picture, it is not likely to make a powerful appeal. Abstract design and symbolism are to be avoided, as they are likely to be misunderstood or not understood at all. (3) Unlike humorous commercial posters, humorous war posters do not attract so much attention, nor do they make so popular an appeal as emotional or even factual posters. Moreover, some people definitely dislike humorous war posters.

Since we have frequently criticised certain health posters of symbolic design, we confess to a "We-told-you-so" feeling in connection with the conclusions reached in this study concerning posters executed along these lines. The study reveals that symbolic posters are misunderstood by one in four who see them. Moreover, they do not at-

tract a great deal of attention and they fail to arouse enthusiasm. This brings to mind a story of a poster that was under consideration by a government agency in Washington. A top-flight artist had prepared a design that employed a great deal of symbolism. It was "previewed" before release by twelve individuals—each of whom had his or her own interpretation of what the poster was supposed to convey. Two out of twelve came very near identifying the message, while the others missed the point completely! (Yet, surprisingly enough, the Russians use a lot of symbolism in their supposedly successful posters! How come?)

The National Tuberculosis Association, through its Health Education Advisory Committee, is now issuing a monthly series of posters for display in industrial plants. The posters are produced in sets of four and may be obtained from local tuberculosis associations throughout the country free of charge. Each poster measures 8 inches by 11 inches and is executed in two colors. The most recent series is devoted to physical fitness, cleanliness, exercise, and the necessity for early medical care. They are ideally suited for bulletin board display in that the captions are brief and pointed and the illustrations simple and appropriate. Health educators should be able to use the posters to advantage, especially in defense areas.

"Effective exhibits were never more important in the health education scheme of things than today." With this opening sentence, the State Committee on Tuberculosis and Public Health of the State Charities Aid Association, 105 East 22nd Street, New York, N. Y., proceeds to discuss in a new brochure certain essentials or "musts" that should be followed in preparing and displaying tuberculosis exhibits. Among the topics

considered are: adapting exhibits to particular groups or audiences, establishing a central theme, selecting current motifs, and choosing exhibit materials. Concerning "coöperative exhibits," the brochure states: "Don't hesitate to 'team up' with other agencies for exhibit space. Sacrifice independence if by so doing you can obtain a preferred location. The best of exhibits fail if out of the line of marching feet. Securing a preferred location is more than half the battle." The brochure is published under a rather ponderous title: "Health Exhibits—For Any Time and Place by Tuberculosis and Health Associations." Write to the agency at the address given above for copies.

"KEEP WELL" CRUSADE

The forces of health education recently gained a strong ally when the Institute of Life Insurance launched a national health campaign built around the theme, "Keep Well and Help Win the War." During June, July, and August, the Institute sponsored a series of five health messages that appeared in newspapers with a combined circulation of 22 million. The keynote of the campaign was expressed in a set of five simple, fundamental rules of good health, formulated in collaboration with Surgeon General Parran of the U. S. Public Health Service, Dr. Morris Fishbein of the American Medical Association, the Medical Information Bureau of the New York Academy of Medicine, and other leading medical and health authorities. These rules were: Eat Right, Get Your Rest, See Your Doctor Once a Year, Keep Clean, and "Play" Some Each Day. In addition, the copy of these messages stressed personal fitness as a patriotic duty to relieve the medical, nursing, and dental professions now seriously overstrained by the increasing demands of the armed services. Life insurance agents were also mobil-

ized in this campaign to spread other health materials prepared by the Institute. This drive to conserve the health of the American people was no doubt of substantial benefit and many health educators have expressed appreciation of the Institute's efforts to help carry the story of good health throughout our nation.

Perhaps the most effective item among the Institute's promotional materials was a poster setting forth the health rules. For simplicity of expression, this poster has seldom been equalled. Generally, when rules are formulated they take on a certain "school teacherish" tint, but in this poster the health advice is put in a refreshing way so that one does not look upon them as "rules," but rather as essentials that one would wish to adopt for good, orderly living. Moreover, the copy brings out certain points that have not been stressed before—for instance, visiting with friends is recommended as a wholesome form of relaxation. In brief, this is a successful poster—both as to copy content and illustrative material. Perhaps the Institute of Life Insurance would permit health agencies to copy it for local use. If interested, write to the Institute at 60 East 42nd Street, New York, N. Y.

MORE ABOUT JARGON

From time to time we have sounded off on the subject of professional jargon. Now Bruce Bliven comes along and does likewise in his first-rate book called "The Men Who Make the Future." Mr. Bliven, we think, hits the nail on the head in the following excerpts:

"Today many scientists, in America no less than elsewhere, believe it is not only undignified but in some way improper to express yourself simply and clearly. There is a doctrine of obscurity which goes straight back in an unbroken line to the mumbo jumbo of the voodoo witch doctor whose patients would never get well if they understood what

he was talking about. It is also allied to the professional bad handwriting of the doctor preparing a prescription. It is a close first cousin of the ponderous verbiage of the lawyer for which there is only one justification: the effort to convince the client that an otherwise dispensable adviser is indispensable. (For an example of the lawyer's reluctance to think straight or write straight, consult your income tax blank, a masterpiece of rhetorical incompetence.) The cult of unintelligibility in our academic life is directly connected with the Germanic tradition in higher education that has done us so much harm these past fifty years, in stressing ever narrower specialization, scholarship for scholarship's sake, the importance of piling one triviality upon another until through a towering monument of uselessness, the scholar's reputation is established.

"In the very recent past, one of the ablest British scientists now living was blackballed for membership in the Royal Society, apparently for the sole reason that he wrote so well that even laymen could understand him. If you want to see the evil influence of this attitude, go to any meeting of any scientific body and listen to the really frightening jargon in which some of the very young scientists couch their papers. It is quite true of course that certain scientific matters cannot be described without using a technical vocabulary, and that mathematical formulae are usually unintelligible to anyone who has not had special training. But the obscurity of many scientists goes far beyond these necessary conditions. For proof of this, I offer two facts: First, that many scientists get simpler and clearer as they grow older: their worst stage is usually when they are showing off as newly fledged Ph.D.'s at a scientific meeting; and second, that the leaders are usually among the best writers."

MAGAZINE ARTICLES

Recent popular magazine articles on health or of medical import:

"The Great Art of Getting Well." Marshall Sprague. *Good Housekeeping Magazine*, August, 1942.

"Worries Are Family Termites." William M. Marston. *Better Homes and Gardens*, August, 1942.

"Mumps." Herman N. Bundesen, M.D. *Ladies' Home Journal*, August, 1942.

"How are Your Nerves?" James S.

Warren. *Cosmopolitan Magazine*, August, 1942.

"Formula for Fitness." Ryllis and Omar Goshin. *Cosmopolitan Magazine*, August, 1942.

"Hotels into Hospitals." Charlotte Muret. *Harper's Magazine*, August, 1942.

"Medical Action at Pearl Harbor." W. H. Michael. *Harper's Magazine*, August, 1942.

(The above is not presented as a complete list and the articles cited are not necessarily recommended.)

JOTTINGS

Education of the public regarding methods for the prevention of mosquito breeding may take on a new significance in some parts of the country as a result of the rather clear identification of the rôle of a common variety of culex mosquito in the transmission of equine and St. Louis encephalitis. Recent epidemic experience in the northwestern part of the country has rather definitely incriminated at least one variety of the culex mosquito as a vector and a reservoir of the encephalitis virus. Heretofore, extermination of this type of mosquito has been undertaken primarily for reasons of comfort. It now appears that this insect may be a very formidable enemy of health, making its extermination an important measure in disease prevention. . . . While it is perhaps a little out of the field of this column, we cannot resist commending to all readers in the public health and medical fields the very unusual paper by Dr. Walter C. Alvarez of Rochester, Minn., on the subject of Constitutional Inadequacy. This paper appeared in the *Journal of the American Medical Association*, July 4, 1942. Few writers have presented in so short a compass as much basic material contributory to an understanding of the limitations and resources of our friends, our fellow workers, and ourselves as does Dr.

Alvarez in this paper. . . . Although the appointment of Dr. Ernest L. Stebbins as Commissioner of Health of the City of New York was announced in the last issue of the *Journal*, we wish to extend our somewhat belated congratulations to him in behalf of all those engaged in health education. Dr. Stebbins's position is one of outstanding importance both locally and nationally. He is highly qualified to fill the post and under his direction it is expected that the health education activities of the department will be carried on with all the resources circumstances afford.

. . . Another gratifying appointment is that of Dr. Frank Calderone as Secretary of the Department of Health of the City of New York. Dr. Calderone assumes this important position after a long and varied experience as a health officer and public health teacher. . . . The increasing toll of industrial accidents in war plants and of accidents affecting war workers has led the National Safety Council to intensify its educational program in this field. Activities of the Council directed toward the elimination of accident factors are being expanded under the direction of Dr. Ned H. Dearborn, newly elected executive vice-president and managing director of the Council. A goal of 5 million dollars has been set to meet the needs of the Council's enlarged educational program. In addition to direct aid to industry, a portion of this fund will be utilized to assist local safety councils and organizations interested in industrial, home, farm, and street safety. . . . A series of articles on various phases of the school health program that merit the thoughtful consideration of all medical and public health personnel is found in the *New York State Journal of Medicine*, issue of August 1, 1942. These articles are indicative of the efforts that are being made to place school health programs on a more comprehensive and genuinely

educational footing. . . . Two excellent films dealing with industrial hygiene are now available. One is produced by the U. S. Public Health Service under the title "Save a Day." It gives a very comprehensive account of the activities of the Industrial Hygiene Division of the National Institute of Health. Examples of effective industrial control of dust and poisons, research in this field, and the work of plant dispensaries are among the subjects covered. The film is one reel in length and is available at reasonable prices in 16 and 35 mm. prints with sound. Write to the Federal Security Agency, U. S. Public Health Service, Washington, D. C. for further information. The second recommended film on industrial hygiene is entitled "We're On the Spot." From the standpoint of content, this is an outstanding presentation. The film emphasizes certain

practical safety precautions applicable to all industrial plants. Prints may be bought or rented from Vision Educational Productions, 509 Fifth Avenue, New York, N. Y. The film is available in 16 and 35 mm. prints, sound or silent versions. There is also a sound-slide version available in 35 mm. prints. . . . For an article on physical education that "makes sense" read "Physical Training in the Army Air Forces," by Major General Walter R. Weaver, in the March-April, 1942, issue of the *Air Forces News Letter*. . . . The Greater New York Safety Council, taking cognizance of "off-the-job" accidents, recently published the following "Victory Verse":

"Joe works hard at his milling machine
Always on the alert—
He crosses the street when the light is green—
Knowing he won't be hurt.
He keeps his home safe—and his family too—
For Joe has a *Victory job* to do!"

BOOKS AND REPORTS

Memorable Days in Medicine. A Calendar of Biology and Medicine—By Paul F. Clark and Alice Schiedt Clark. Madison: University of Wisconsin Press, 1942. 305 pp. Price, \$2.00.

This calendar furnishes a practical way of finding at a glance the dates of births and deaths of prominent physicians and of notable events in medicine. There are also included notes on many hospitals with the dates of their foundation, the names of the architects who built them, and some of the prominent names connected with them; types of medicine in the various countries of the world, a list of Saints who in one way or the other must be remembered in connection with the medical art, and a number of other interesting facts. There are sketches of some 469 physicians which include most of the great founders as well as some of the notorious quacks who flourished from time to time. These are necessarily short but tell why these men were great, and in many instances, interesting personal characteristics are given.

As far as possible the birth dates rather than those of the deaths are given, but there is difficulty in ascertaining some of these, even those of the most famous. The compilation has engaged the authors for a number of years and has served in part as a basis for exhibits on medical history and biography in the Memorial Room of the University of Wisconsin Medical School.

The selection of subjects is good, but presumably many readers will detect omissions which they regret. The authors have foreseen this and tell us they have omitted many of their own favorites. The cross-referencing is

fairly complete, though there are omissions which might leave the average reader with a false impression of actual priority of discoveries. A notable example of this concerns the discovery of ether anesthesia.

There is a good biography and an excellent index. The volume is a distinct addition to the study of medical history, to which too little time is given in practically every medical school, in spite of the fact that great leaders and teachers, like Welch and Victor Vaughan, have stressed its importance in medical education.

The printing and make-up are excellent. There are 29 illustrations, most of which are of persons. The book opens for January 1 with the Hippocratic Oath, which the authors offer as the best of all New Year's resolutions.

MAZÏCK P. RAVENEL

Outlines of Food Technology—By Harry W. von Loesecke. New York: Reinhold Publishing Corp., 1942. 505 pp., 84 ills. Price, \$7.00.

With the present interest in nutritional problems, it is fortunate to have a book dealing with food technology. This book will be very valuable to many nutrition workers since the information is given in rather complete but concise form. Practically all available foods and food products are discussed both from the point of view of production, and methods of handling before purchase by the consumer. Special chapters are devoted to storage and marketing of fruits and vegetables and preservation of foods by freezing.

No attempt is made to give the nutritive value of the different foods or the effect of processing on the degree of retention of the more important nu-

trients. Since the author had the advice of some of the leading authorities in food technology during the preparation of this book, the information can be accepted with confidence.

This book will be a very handy reference to public health workers.

C. A. ELVEHJEM

Source Book of Medical History
—By Logan Clendening, M.D. New York: Hoeber, 1942. 685 pp. Price, \$10.00.

Dr. Logan Clendening has rendered a useful service in compiling a *Source Book of Medical History*. The compendium spans the time from 1900 B.C. to 1895 A.D.; from the Kahun Papyrus to Roentgen's contribution "On a New Kind of Ray."

The compiler's lot is never fully a happy one for try as he will he is bound to displease. He is naturally exposed to the critical challenge, "why this selection and not *that* other one?" and most readers of this work are likely to have unique ideas as to what *should* have gone into the collection.

This much, however, can be said for Dr. Clendening's compilation—that whatever may be its sins of omission—it is without those of commission. Every item given is worthy of inclusion. And especially noteworthy are the texts culled from non-medical literature which properly belong to medical history, items such as those drawn by the author from Aristophanes' "Plutus," Plato's "Phaedo," and from the writings of Molière, Thackeray, Dickens, and others.

The virtue in going back to the original sources is to gather a first hand appreciation of the men and the works that are the *Bausteine* of medical history. But few of the selections included in the Clendening book are given in their entirety. Hence, the question arises. "Can one envisage the block by its chips?" The compilation really

represents a double selection: first, as to what works, and second, as to what fragments thereof were to be published. The author palpably had to choose between including fewer "whole" examples, and giving a larger number of partial ones. He chose the latter. The end result is rather good. The work certainly offers a good and instructive sampling of the classics in medicine.

It can be read as a sketch book of medical history, for the chronological arrangement of the abstracts does offer one a rather loose and large outline of "progress in medicine."

Each chapter is preceded by a brief discussion of the period dealt with, and a good reference list is provided for each period.

IAGO GALDSTON

Health in Schools—Twentieth Yearbook: Includes Report of the Executive Secretary and List of Members. American Association of School Administrators: 1201 Sixteenth Street, Washington, D. C., 1942. 544 pp. Price, \$2.00.

This is the Report of 1942 of the Commission on Health in Schools representing the American Association of School Administrators. It starts by discussing the Organization and Administration of the General Program and the Guidance of Individual Pupil Health. The chapter on Guidance is largely a presentation of procedures in school health services.

These general chapters are followed by discussions of health instruction, physical education and recreation, mental hygiene, special programs for the physically exceptional, the control of communicable disease, emergencies and their treatment, the type of environment needed to make possible a healthful school, the functions and preparation of school health personnel, as well as administrative practices, coördination of health agencies, and the legal aspects of this intensively specialized program.

The value of the report is greatly enhanced by a bibliography divided by chapters. A section on methods of appraisal of the program, in which various types of tests and measurements are discussed, gives great aid to the school or health administrator who really wishes to know the status and progress of the various activities involved. School health programs fail largely from lack of information as to the program, as to what other schools are accomplishing, and as to the improvements and checks that are possible.

Since this text will go into the hands of a great majority of our school administrators, it should have great influence for good on their thinking and procedures.

C. H. KEENE

Rabies—By Leslie T. Webster, M.D. *New York: Macmillan, 1942.* 168 pp. Price, \$1.75.

This book contains less than one hundred pages of reading matter and fifty or more pages of sketches or graphs, tables, references, and appendices.

The author recognizes that a simple, critical, and fairly inclusive treatise on rabies should be available to all and with this in mind directs chief interest toward giving the best answers of the day to practical questions. The subject matter is focused on two chief problems and accordingly the text is prepared in two parts, diagnosis and prevention.

The book does not furnish a solution to all questions pertaining to rabies but is a clear, concise, and accurate assemblage of the essential information and brings the subject up to date. It consists mostly of facts and does not theorize to any extent. One who reads its contents will gain thereby and will not be left in darkness on the subject.

From the standpoint of diagnosis in suspected animals, and of prevention of human cases by vaccination, the mouse test which was developed by the author is recommended as a measuring tool, to

be used as a means of final decision in the diagnosis and as a quantitative measure of potency of vaccines.

The author gives a brief critical but fair review and analysis of controlled experiments on vaccination, showing inconsistency of results, the necessity of controlled field experiments, the lack of evidence that the use of vaccine after exposure offers any protection, recommends that persons exposed should have treatment only with vaccines proved potent and outlines a procedure to be followed in exposed persons. He discusses the probability of a difference in strains of virus but apparently overlooked differences indicated by some of the controlled experiments.

The second chapter "Is Rabies a Myth?" does not seem to fit into the sequence of the descriptive text and might better not have been included in the book or, with the last paragraph omitted, could have been included in the first chapter. Also there might be some difference of opinion as to whether the term "myth" is properly used in this sense, and if so some substantive reasons for the question should have been given.

The book contains much good sense and a lot of practical knowledge which should be available for ready reference to students, researchers, physicians, veterinarians, and other interested persons, especially those having some knowledge of the disease.

M. F. BARNES

Family Nutrition—By Rachel M. Winlock, Emerson R. Sausser, Joseph Stokes, James J. Waygood, Anna de Planter Bowes, Pauline Berry Mack. *Published by the Philadelphia Child Health Society, 1942.* 106 pp. Free.

A committee of six medical and nutrition scientists has written a compact, authoritative, easily read, well illustrated monograph on "Family Nutrition." Its popular style adapts it to

the use of lay groups. Its complete bibliography is valuable for the person who may wish to read original sources.

The following chapter titles: Nutrition and the Nation's Fitness, the Nutritional Status of Human Beings, How Nutritional Status in Human Beings Is Measured, The Dietary Value of Common Foods. The Nutritional Needs of People, The Relationship of Food Intake and of Appetite to Nutritional Status and to Resistance to Disease, Balanced Diets and Balanced Budgets, are self-explanatory as to content.

Chapters II and III give suggestions and references which might be helpful in planning large scale mass studies using human subjects. To the reviewer this seems particularly useful at this time when communities need to learn more about the nutrition status of their own families.

The monograph is offered for free distribution in the interest of National Defense. Its publication was made possible by a Grant-in-Aid from the Beneficial Industrial Loan Corporation. Those teaching nutrition in a community program, in formal school classes, and others, may obtain single copies while the supply lasts by writing to the Philadelphia Child Health Society, 311 South Juniper Street, Philadelphia, Pa.

AGNES ENGLISH VAUGHN.

The People Against Tuberculosis—The Story of the Christmas Seal—

By Leigh Mitchell Hodges. New York: National Tuberculosis Association, 1942. 54 pp. Price, \$1.00.

From an acorn to a sturdy oak in thirty-five years may well epitomize this fascinating story of a simple idea. The value of the tale is enhanced by the fact that the author was one of the planters of the acorn and has witnessed its growth to dimensions far beyond his fondest dreams. While the idea originated in foreign soil—Denmark—it was in the United States of America

where the soil, climate, and conditions made for its maximum development.

The Christmas Seal has been the tie which has bound together the complex organization of social forces which we today call the "tuberculosis movement." Mr. Hodges reveals dramatically how the germination of the idea was beset with all but disastrous difficulties. He gives due credit to Einar Holboell of Denmark for the idea of the Christmas Seal and Miss Emily Bissell of Wilmington, Delaware, for the adaptation of the idea in this country. Woven into the story of the Seal is the scientific side of tuberculosis work.

Throughout the account, one is impressed with the basic factors which go to make a successful social effort—a need to be met; a program for meeting that need; the translation of that program into a working organization; the adequate financing of the organization and intelligent leadership. In short the story of the Christmas Seal is also the story of the other factors in the successful combat of the scourge of society.

The little volume is well printed, adequately illustrated, and dramatically, though truthfully, written. Its publication served to mark the fiftieth anniversary of the founding of the first voluntary organization in the world—The Pennsylvania Society for the Prevention of Tuberculosis in 1892.

ROBERT G. PATERSON

Preventive Medicine in Modern Practice—Edited Under the Auspices of the Committee on Public Health Relations of the New York Academy of Medicine. New York: Hoeber, 1942. 851 pp. Price, \$10.00.

Here is a book the like of which has long been awaited by the medical profession, and although medical students are unaware of the fact they too have badly needed such a volume. *Preventive Medicine in Modern Practice* is essentially what the title implies: a

discussion of the problems of preventive medicine which are encountered by the physician in his daily practice and, in so far as possible, the presentation of solutions of these problems.

The range of subjects covered in this volume is comprehensive: socio-biological aspects of preventive medicine, 56 pages; clinical aspects, 565 pages; environmental aspects, 109 pages; organizational aspects, 93 pages. This seems a sound proportional allotment of space to these respective major divisions, particularly so when one considers that this volume is designed for the practitioner and student rather than for the public health officer. But even for the latter, especially in fields from which he has permitted his routine work to withdraw him, there is here presented a great body of factual information and to no small extent a reorientation.

Aside from the value of this book as a book, the fact that it has been published by the New York Academy of Medicine is of unusual significance. The Academy is one of the great professional organizations of the United States. It has acquired a reputation for sanity, realism, and courage. While it observes a safe conservatism, it is not unwilling, if the occasion arises, to face and consider and, if indicated, to act favorably upon any pertinent medical problem, even though the consideration and action be outside the realm of convention and tradition. That such an organization has published this volume not only gives assurance of the book's soundness, but indicates the Academy's conviction that preventive medicine presents to the practitioner both an opportunity and an obligation.

The volume is not the product of any one author, but represents the joint effort of a number of authorities, carefully selected because of competence in their respective fields. Always, of course, a volume so produced, while strong in exactness and detail, carries

with it the danger of non-continuity and spottiness. In this instance lack of uniformity and unity are satisfyingly offset by what must have been a very hard working editorial committee of physicians eminently suited to the task. Incidentally, the preface lays down a fine philosophy.

H. S. MUSTARD

Civil Defense Measures for the Protection of Children: Report of Observations in Great Britain, February, 1941—By Martha M. Eliot, M.D. Washington, D. C.: Children's Bureau, 1942. 186 pp. Price, \$30.

No one interested officially or otherwise in the health and welfare of mothers and children can well afford to miss Dr. Eliot's report on her studies made in Great Britain as a member of the United States Civil Defense Mission which was sent to that country early in 1941. Since Pearl Harbor, the protection of children under bombing, the effect of war on children, and the many problems incident to evacuation from target areas are matters that have taken on an urgent significance for Americans.

Dr. Eliot of all persons was the one to set forth for us the details of the British experience and the lessons to be learned. It may be that some of the medical and social unpreparedness in cities and rural areas will be corrected on this side of the Atlantic by the time we are bombed. But as a preliminary to correcting this situation we shall have to give up a part of our smug complacency promptly.

With all the blueprinting that this report makes possible for us, we will do well if we can approach the success of our British friends in child care under bombing. The long range planning and training is described and then the first Major Evacuation from city to country during the four days, September 1-4,

1939. A total of 607,635 adults and children were removed from London to rural areas without a casualty. There were roughly 350,000 school children with their teachers, and 230,000 mothers with children under 5 years old. The others were expectant mothers and the handicapped and the blind.

The early chaos due in part to the lack of trained social workers in the reception areas and the inability to fit particular children into rural household billets on a selective basis resulted in a trek back to the city. This trek, of course, was also due to the failure of the bombing to begin. The second general evacuation from London and other cities in September, 1940, found better medical inspection services to control pediculosis, scabies, and impetigo. Enuresis was also an outstanding worry. Dr. Eliot's description of the ingenuity of official and voluntary agencies (The Women's Voluntary Services—W.V.S.—particularly) working closely together to meet the unexpected makes her well documented report indeed a fascinating one to read.

HUNTINGTON WILLIAMS

Nursing: An Art and a Science—
By Margaret A. Tracy. (2nd ed.)
St. Louis: Mosby, 1942. 754 pp.
Price, \$3.50.

Nursing, An Art and a Science has been revised to make it more useful as a textbook for student nurses. It is divided into three parts: General Considerations, Diagnostic Procedures, and Therapeutic Procedures. Supplementary to the text is a list of commonly used nursing procedures. In the preface to the second edition the author states, "Wholly new is the chapter concerned with hospital housekeeping . . ." "The chapter on charting has been greatly expanded."

This book, written primarily as a text for student nurses, is excellently planned and organized. The subject is

simply and logically presented, and can be followed readily by the student. An attractive feature is the use of 183 well selected illustrations. The nurse is given recognition as a health teacher, and opportunities are planned for her to integrate her teaching while rendering regular daily duties. This is an excellent procedure.

Although the second edition of this book is an improvement on the one previously published, the inclusion of nursing procedures is questionable. The author acknowledges the procedures are used in the University of California Hospital and cannot be adopted wholly by any other institution. The printing of them covers 162 pages. The book is heavy and unwieldy.

The volume seems well adapted for the purposes for which it was intended. It is recommended for use in schools of nursing and as a reference book for public health nurses.

FRANCES F. HAGAR

Manual for the Conduct of Classes for Expectant Parents—
By Ellen D. Nicely, et al. (2nd ed. rev.) (1001 Huron Road) Cleveland: Child Health Association, 1942. 167 pp. Price, \$1.50.

The fact that the Cleveland Child Health Association, under Dr. Richard Bolt's leadership, has been able to maintain such successful classes for expectant parents on a community-wide basis for both well-to-do patients and for low income groups has long caused comment. It is therefore helpful to have a detailed account, lesson by lesson, of the material that is presented in these classes. The new manual is helpful in that it also gives samples of publicity folders, admission card, etc., in the classes. The material will be useful to anyone who is faced with the problem of developing educational work for expectant parents.

LEONA BAUMGARTNER

Personality and Mental Illness: An Essay in Psychiatric Diagnosis—By John Bowlby, M.D. New York: Emerson Books, Inc., 1942. 280 pp. Price, \$2.75.

This book represents a serious attempt to bring about a greatly needed new orientation in an old subject. To this end, the author who is Psychiatrist at the London Child Guidance Clinic, and Physician to the London Clinic of Psychoanalysis, has made his approach to the problems of mental disease by evaluating basic personality traits rather than the surface symptoms of mental disorder.

A discussion of the work on personality types and their relations to neuroses and psychoses done in the past including modes of psychiatric classification proposed by Kraepelin, Bleuler, Adolf Meyer, Kretschmer, Kahn and others introduces the various aspects of this complicated field of scientific investigation. This is followed by a schedule of personality traits characteristic of the major types of personality, with emphasis on the schizoid and syntonetic varieties, which will be useful in distinguishing them, and a practical clinical method of measuring and describing personality forms. Tabulations of these traits for 36 patients who have had a psychosis and for 29 patients suffering from neurotic symptoms are presented, with descriptions of typical unstable personalities. Thirty-three traits are selected as being particularly significant for diagnostic purposes.

The section of the book devoted to the psychoneuroses contains many worth while suggestions for diagnosis and regrouping of the forms, in a classification scheme that has some clinical advantages. As the author himself states, a great deal of the subject is still

in stages of research. Throughout the text a number of attractive research leads are offered in the field of psychopathology where original work is becoming more and more urgent.

Although many of the conclusions are tentative in character, the ideas presented and the method of study proposed make the book a valuable contribution to the literature on psychiatry, and students of this subject will find much of interest in its pages.

NOLAN D. C. LEWIS

Our Sex Life—By Fritz Kahn, M.D. (2d ed.) New York: Knopf, 1942. 459 pp. Translated from the German by George Rosen, M.D. Price, \$5.75.

This book is written for everyone, but it is doubtful if everyone would profit by its perusal. It covers a wide and problematical field of information. One could question whether its general reading would be very helpful. It tries to cover sex from physiology to pathology.

Many statements are either inaccurate or not proved. Though some of these inaccuracies are not very important, they do tend to discredit the author as an authority.

The subject seems to be approached more from the standpoint of the individual than of society. It is questionable if the cumulative experience of mankind in developing civilization can be ignored regarding sex as well as other important matters. One might suggest that civilizations which have become engrossed in the various pleasures of living have either fallen or deteriorated and failed to progress.

The author, recognizing the biologic importance of sex, seems to stress the development of the sexual drive rather than the fundamental biologic purpose of sex.

FRED L. ADAIR

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Captain of the Illnesses—Standing first among the disabling diseases, arthritis cannot be ignored by any health worker, however little he may be able to do about it. So this primer, prepared by an outstanding committee, becomes an indispensable addition to our professional libraries.

AXON. Primer on Arthritis. J.A.M.A. 119, 14:1089 (Aug. 1), 1942.

Health in Schools—Ten considerations in formulating any school health program are set forth to open a symposium: a measured viewpoint, based upon ascertainable fact, keeping within bounds of scientific knowledge, and attainable goals, avoiding outworn traditions, seeking quality rather than quantity of service, providing follow-up, utilizing all professional services, always respecting the chief objectives of schooling, and coördinating with community services—these are the ten.

BAUER, W. W. School Health and the Nation's Health (and two related papers). New York State J. Med. 42, 15:1454 (Aug. 1), 1942.

Soldier's and Sailor's Shots—Just in case someone asks you: smallpox vaccine, typhoid vaccine (with paratyphoid A and B added, again), and tetanus toxoid are given to all military personnel. Yellow fever vaccine, originally administered to all, now is to be given only to those about to depart for areas where the disease is endemic. Cholera and plague vaccines are also ready for troops and naval forces who are to be sent to countries where they may be exposed to these diseases. Typhus vaccine is under study.

ENDERS, J. F. The Present Program for the Immunization of Military Personnel.

New Eng. J. Med. 227, 5:162 (July 30), 1942.

More Praise for Sister Kenny's Method—In this Canadian symposium on poliomyelitis and encephalitis, there are eleven papers on the epidemiology, diagnosis, pathology, and treatment (including the Kenny Method) of poliomyelitis and three on encephalitis. There is so much here that this note can do no more than to call your attention to the existence of the mine of information.

JACKSON, F. W., *et al.* Poliomyelitis and Encephalitis. Manitoba, 1941. Canad. Pub. Health J. 33, 6:242 (June), 1942.

Deficiency States, Clinical and Subclinical—Some clinicians, who recognize only the frank manifestations, insist that deficiency diseases are rare. But researchers who have conducted extensive surveys know that deficiency states are widely prevalent. The author discusses some solutions for this seeming impasse. Incidentally, he points out that some changes previously thought to be attributable to the aging process are manifestations of dietary deficiencies.

KRUSE, H. D. A Concept of the Deficiency States. Milbank Quart. 22, 3:245 (July), 1942.

Plumbism—Through its laboratory service, a local health department was able to study the incidence of lead poisoning in its city. Three out of five cases were among children (from chewing lead-painted toys). The adult cases were mostly of industrial origin.

MCDONALD, J. M., and KAPLAN, E. Incidence of Lead Poisoning in the City of Baltimore. J.A.M.A. 119, 11:870 (July 11), 1942.

Health Under Nazi Rule—Though we know little of current conditions in Paris, the author of this paper brought with him, when he left near the end of 1941, some suggestive statistics. Tuberculosis increased during the first year of food restrictions, and mortality was highest in the most neglected age group—the old people. It is reasonable to assume that conditions are much worse now.

MINOLI, R. F. Food Rationing and Mortality in Paris, 1940–1941. *Milbank Quart.* 20, 3:213 (July), 1942.

Help!—A thousand-plus health departments answering a questionnaire report that they employ full-time more than 17,000 technically trained persons, have existing vacancies for another 1,000, and need still another 4,000 to take care of wartime activities. Hospitals are short-handed too.

PERROTT, G. ST. J., and DORN, H. F. Current Needs for Health Personnel. *Pub. Health Rep.* 57, 27:997 (July 3), 1942.

Sex and Sickness—Women are more frequently ill than men, but mortality rates are higher among the males. The authors looked into this seeming paradox of sex differences in ill health. Though the weaker sex undoubtedly enjoys more illnesses, the laughingly called stronger sex is hit harder when sick. You'll want to see the statistics.

PREAS, S., and PHILLIPS, R. The Severity of Illness among Males and Females. *Milbank Quart.* 22, 3:221 (July), 1942.

Wartime Nursing Adjustments—Nurses by thousands are needed by the Army and Navy. The reduced nursing personnel that remains at home must be utilized most effectively to cover the greatly increased need for nursing in factories, clinics, health agencies. The job of making necessary adjustments, selecting trained personnel and trainees, and planning community services is a large order. All of us should know how it is being done, and this paper tells us.

SHEATHAN, M. W. Public Health Nursing in the War. *Pub. Health Nurs.* 34, 7:371 (July), 1942.

Needless Worries Department—There is no need for fear that we shall have insufficient or inadequate food supplies for ourselves, and to meet the "fillable" needs of our allies in 1942 or the years that lie ahead, concludes this nutritionist-economist.

WELLS, O. V. Can We Produce Enough Food? *Pub. Health Nurs.* 34, 7:361 (July), 1942.

"Victory—the Only Plank"—“The professional, long operating at the will of the people, long granted special privileges by the people, tends to forget the source or the purpose of that privilege.” Addressed to sanitary engineers, this admonition may well be taken to heart by all of us, in these days when our country has but one purpose.

WOLMAN, A. A Platform for the A.W.W.A. in the Coming Year. *J. Am. Waterworks Assn.* 34, 7:979 (July), 1942.

THE ST. LOUIS ANNUAL MEETING,
OCTOBER 27-30

THE program of the Association's Wartime Conference on Public Health was published in the August issue. Elsewhere in that issue, specifically on page 847, the membership was assured that plans for the 71st Annual Meeting were proceeding as scheduled and that there was every reason to believe they would be carried through. It was pointed out that professional public health workers need to come together, as England has discovered, not in spite of the emergency, but because of it, in order that new information and experiences may be shared for the benefit of the nation. The health protection of the civilian population, to which we as a profession are dedicated, and the health protection of the armed forces, in which many Association members are now engaged as individuals, are essential to the successful prosecution of the war. Attendance at St. Louis will help us fight the war better.

Since the August *Journal* went to press, Surgeon General Parran has agreed to preside at the General Session on "War and the Health Department," on Wednesday morning, October 28. Hon. Charles P. Taft has been invited by the Program Committee to speak from the national standpoint; Dr. Wilton L. Halverson, Los Angeles County, will speak as the Health Officer of a western county and Dr. Alfred Burgdorf, Hartford, Conn., as the Health Officer of an eastern city.

Word has come that three distinguished representatives of Great Britain will be present, in addition to the Hon. Malcolm MacDonald, High Commissioner for Canada, whose attendance was announced previously. Sir John Orr, eminent nutritionist, will speak at a luncheon in his honor sponsored by the Food and Nutrition Section, on

Tuesday, October 27. Professor W. M. Frazer, Medical Officer of Health of the City and Port of Liverpool, Medical Officer to the Liverpool Education Authority and Professor of Hygiene at the University of Liverpool, will address the Health Officers Section. Dr. E. R. A. Merewether, representing the Ministry of Labour, factory medical inspector, and Lecturer on Industrial Hygiene at Aberdeen University, will be featured on the Industrial Hygiene Section program. Canada is sending a number of program participants as well as numerous delegates, and several of the Latin American republics will be represented.

Three conferences not described in the preliminary program have been definitely scheduled. One is a conference on Orthopedic Nursing, sponsored by the Joint Orthopedic Nursing Advisory Service, to be held on Saturday, October 24, and Sunday, October 25. It is planned primarily for nurses actively engaged in crippled children's services. Registration is limited to thirty, and will close October 1. Applications should be addressed to Jessie L. Stevenson, R.N., Joint Orthopedic Nursing Advisory Service, 1790 Broadway, New York, N. Y.

Another is a Conference of Directors of Local Health Service, for which arrangements are being made by Dr. Ben F. Wyman, Director of the Division of Rural Sanitation and County Health Work of the South Carolina State Board of Health. Very successful conferences under the same auspices were held last year at Atlantic City.

The third is new, and noteworthy not because of that alone, but because it is the culmination of a desire of several years' standing on the part of those who teach Preventive Medicine

and Public Health to undergraduate medical students to meet for purposes of acquaintanceship and discussion of mutual problems. A meeting of these "Associated Teachers of Preventive Medicine" will be held on Friday, October 30, at 9:30 A.M. Wilson G. Smillie, Professor of Public Health and Preventive Medicine, Cornell University Medical School, will preside. Dr. Leland W. Parr of the George Washington University Medical School, Washington, D. C., is acting as Secretary for the group and will be glad to receive suggestions for the meeting, which is being set up as an informal discussion of the problems of contemporary importance in this field of medical education.

Certain programs intentionally incomplete a month ago are being rounded out in tune with the times, among them the sessions of the Ninth Institute on Public Health Education. This has been printed in full as a sepa-

rate and is available on request to the Central Office.

Reprints of the Preliminary Program from the August *Journal* will be supplied to anyone who wishes to send them to colleagues who have not access to the magazine.

The Chairman of the St. Louis Local Committee, Dr. Joseph F. Bredeck, announces that local affairs are in good order and that every effort will be made by him and his coworkers to fill the brief intervals between scientific sessions with visits to St. Louis institutions where inspiration and new ideas may be secured.

Reservations at the headquarters hotels, the New Jefferson and the Statler, should be made well in advance of the meeting, as should train reservations. Transportation is an important factor, and we can help the railroads, and assure our accommodations by reserving space and buying tickets early.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

E. J. Beckner, M.D., 106 East Second, Pratt, Kans., Director, Pratt County Public Health Unit

Leo Bernstein, M.D., M.P.H., Board of Health, Lihue, Kauai, T. H., Health Officer, Territorial Board of Health

John S. Coughlan, M.D., County Health Officer, Berkeley Springs, W. Va.

George R. Good, M.D., M.P.H., 1216 14th Ave., Altoona, Pa., District Medical Director, State Dept. of Health.

Oscar Harvey, M.D., 3200 W. Douglas, Wichita, Kans., Asst. Health Officer, Sedgwick County Health Dept.

Harvey B. Henry, M.D., 802 Norwood Bldg., Austin, Tex., City Health Officer, Luling, Tex.

Lester J. Kantor, M.D., D.P.H., Sells Indian Agency, Sells, Ariz., Senior Physician, U. S. Indian Service

Everett A. King, M.D., Tri-county Health Unit, Hardinsburg, Ky., Director

Elias W. Langs, M.D., Fairfax County Health Dept., Fairfax, Va., Asst. Health Officer, Northern Health Dist.

S. J. Maydet, M.D., 216½ E. Monroe, Springfield, Ill., District Health Supt., State Dept. of Health

William Pratt Scarlett, M.D., M.S.P.H., 205 Brown St., Morrilton, Ark., Director, Field Experience Center, State Board of Health

Harry F. Smith, M.D., Klamath Agency Hospital, Klamath Agency, Ore., Health Officer, U. S. Indian Service

Jules R. Thebaud, M.D., Service National d'Hygiene, Palais des Ministeres, Port au Prince, Haiti, Director General

Laboratory Section

William A. Boyles, M.S., State Board of Health, Jacksonville, Fla., Assoc. Bacteriologist, U. S. Public Health Service

L. Amy Darter, 125 Panoramic Way, Berkeley, Calif., Supervising Bacteriologist, State Bacteriological Laboratory

Frederick W. Hindley, Health Dept., City Hall, Newport, R. I., City Bacteriologist
 Katherine Kesling, M.S., 4003 McCorkle Ave., Apt. 201, Charleston, W. Va., Junior Diagnostic Bacteriologist, State Hygienic Laboratory

Nathan C. Kirsch, M.S., 268 Hale, New Brunswick, N. J., Asst. to Head of Sterile Production Laboratories, Schering Corp.

George W. Malaney, 2029 Cleveland Ave., S., Canton, Ohio, Asst. Scientific Aide, U. S. Public Health Service

Vital Statistics Section

Myron S. Heidingsfield, A.M., Ph.D., College of William & Mary, Williamsburg, Va., Asst. Professor of Statistics

Engineering Section

Lieut. A. Harry Bliss, 1104 West 8th St., Santa Ana, Calif., Army Air Force Sanitary Corps

Corp. Charles S. Laubly, Station Hospital, Tyndall Field, Fla., Medical Corps, U. S. Army

Industrial Hygiene Section

August Baier, M.D., 1158 Chautauqua Pk., Des Moines, Iowa, Medical Director, U. S. Rubber Co.

Francis R. Holden, M.A., Ph.D., 835 Fifth St., Oakmont, Pa., Industrial Hygienist, Industrial Hygiene Foundation

Watson F. Rogers, M.D., American Viscose Corp., Parkersburg, W. Va., Industrial Physician

Food and Nutrition Section

Grafton D. Bowers, D.V.M., R. R. 3, Baton Rouge, La., Veterinary Sanitarian, East Baton Rouge City Parish Health Unit

Marie E. Dohm, M.A., 737 S. Wolcott St., Chicago, Ill., Nutritionist, Cook Co. Public Health Unit

Rose E. Koshetz, M.S., Hotel Woodward, 210 W. 55th St., New York, N. Y., Dietitian, Adelphi Hospital, Brooklyn, N. Y.

Reginald C. Sherwood, M.S., Ph.D., 2010 E. Hennepin Ave., Minneapolis, Minn., Manager, Research Laboratories, General Mills, Inc.

John B. R. Woolley, 307 Encine, San Antonio, Tex., Director of Food Control, San Antonio Health Dept.

Maternal and Child Health Section

Bret Ratner, M.D., 50 E. 78th St., New York, N. Y., Clinical Professor of Pediatrics, New York Univ.

Elizabeth P. Rice, M.S., 789 Howard Ave.,

New Haven, Conn., Director of Medical Social Service, New Haven Hospital

Marian E. Russell, M.S., 205 W. Wacker Drive, Chicago, Ill., Exec. Sec., American Association of Medical Social Workers.

Catherine S. Sherwood, M.D., 121 N. Fir St., Ventura, Calif., Pediatrician, Div. of Maternal and Child Hygiene, County Health Dept.

Public Health Education Section

Lloyd W. Coe, State Capital, Room 1006, Lincoln, Nebr., Asst. Director, Div. of Public Health Education, State Dept. of Health

Miriam R. Hahn, 146 Filbert St., Hamden, Conn., Staff Member, Committee on Hygiene of Housing, A.P.H.A.

Kenneth F. Herrold, M.S.P.H., Bucknell Univ., Lewisburg, Pa., Instructor, Div. of Hygiene and Public Health

Anton T. Jirik, 1245½ W. Gouvernor St., Springfield, Ill., Supervisor of Exhibits, State Dept. of Public Health

Lillian C. Maynard, M.Ed., Deer Island, Boston, Mass., Student, Massachusetts Institute Technology

Bernice E. O'Brien, M.A., R.N., Glynn County Board of Health, Brunswick, Ga., Supervisor of Nurses

Frederic C. Woodward, LL.M., 122 S. Michigan Ave., Chicago, Ill., Chairman, State-wide Public Health Committee

Public Health Nursing Section

Marguirete M. Boom, 1004 Main St., Evanston, Ill., Public Health Nurse, Evanston Dept. of Health

Christine Causey, R.N., M.A., City Health Dept., New Orleans, La., Director of Nursing, Child Welfare & Community Health Assn.

Betty K. Clark, R.N., 1421 Home Ave., Berwyn, Ill., Public Health Nurse, Berwyn Health Dept.

Kathleen Clark, Health Dept., Winfield, W. Va., Public Health Nurse

Dorothy I. Fowler, Paris-Lamar County Health Unit, Paris, Tex., Senior Public Health Nurse

Mildred E. Gonyeau, C.P.H., 12 Olcott Ave., Bernardsville, N. J., Director, Visiting Nurse Association of Somerset Hills

Mary Matula, Minot-Ward Health Unit, Minot, N. D., Nursing Supervisor

Alma Kee McCracken, Box 707, Waynesville, N. C., Supervising Nurse, District Health Dept.

B. Elinor Suchy, R.N., 1621 South 61st Court, Cicero, Ill.

Juanita B. Williams, R.N., Box 1703, Pompano, Fla., Project Nurse, Florida Migratory Labor Health Assn.

Anastasia Wilson, R.N., S. Central Dist., Health Unit, Buhl, Ida., Public Health Nurse

Epidemiology Section

Howard P. Steiger, M.D., Christian County Health Dept., Hopkinsville, Ky., Venereal Disease Clinician, U. S. Public Health Service

Capt. Benjamin Zimmerman, M.C., Lovell General Hospital, Fort Devens, Mass., U. S. Army

Unaffiliated

William H. Clark, Jr., 3583 Life Sciences Bldg., Berkeley, Calif., Assoc. in Public Health, Univ. of California

Joy R. Dulaney, M.S., 220 Belvedere St., Lynchburg, Va.

Amelia L. Foote, 330 Willow St., New Haven, Conn., Student, Yale Dept. of Public Health

MERIT SYSTEM CONSULTATIONS

PROVISIONS will be made at the 71st Annual Meeting of the American Public Health Association in St. Louis, October 27-30, for consultations between those concerned with the administration of merit system plans and

the staff of the Association conducting the Merit System Study under the auspices of the Committee on Professional Education. Appointments for consultation on this subject with Dorothy Deming, R.N., may be made through the Association office in the Auditorium.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

U. S. CIVIL SERVICE COMMISSION

The Commission has announced again its need for public health nursing consultants in war work. The new announcement now provides for 5 grades and for appointments in the Children's Bureau, Department of Labor, U. S. Public Health Service, and Federal Security Agency. Salaries range from \$2,600 to \$5,600 a year. No age limits have been set. Positions exist both in the United States and foreign countries. War service appointments will be made to extend generally for the duration of the war and no longer than 6 months afterward. Duties are to carry out, in accordance with the rank of the position, nursing or nursing education programs; and to act in advisory capacity to Federal agencies, or to State, County, and municipal organizations.

There will be no written test, qualifications being judged solely from review of experience, education, and training of applicants. Persons applying must have completed a 4 year course in a recognized college and 1 year's special program of study in public health nursing approved by the National Organization for Public Health Nursing; must also have graduated from an accredited school of nursing affiliated with a hospital having a daily average of 100 or more bed patients; be registered nurses in a state or territory of the United States or the District of Columbia, and have had appropriate general public health nursing supervisory experience. Additional credit given for completion of approved college course in statistical analysis, public health nursing, supervision, social hygiene, tuberculosis control and maternity, pediatric or orthopedic nursing; also for certain appropriate experience as instructor, consultant, or investigator.

For positions in Children's Bureau additional progressive experience in specialized fields of maternal or child health is required for the top grade and may be substituted for part of the general experience prescribed for the other grades.

Applications must be filed with the U. S. Civil Service Commission, Washington, D. C., and will be accepted until the needs of the service have been met.

Forms may be obtained direct from the Commission or at any first or second class post office.

Merit System Council, Oregon State Board of Health and Crippled Children's Division, has announced merit examinations in practically all professional public health fields, including Health Officers, Nurses, Sanitary Engineers, Laboratory Workers, Vital Statisticians, Consultants in the fields of Health Education, Hearing and Vision, Nutrition, Oral Health and Physiotherapy. Two clerical positions, Fiscal Worker and Administrative Clerk are included in this list as is also the position of Merit System Personnel Technician.

Interested persons may get full particulars regarding the positions and examinations by writing H. J. Sears, Merit System Supervisor, P. O. Box 88, Portland, Ore.

The Indiana State Personnel Division, 141 South Meridian Street, Indianapolis, announces that applications may be filed at any time until further notice for the following positions:

Orthopedic Nursing Consultant I (women only) ..	\$150-200 mo.
Physician I (General)	165-250 mo.
Physician II (General)	250-325 mo.
Physician II (Tuberculosis)	250-325 mo.
Physician I (Psychiatric) ..	185-265 mo.
Physician II (Psychiatric) ..	250-325 mo.
Local Public Health Director	300-360 mo.

The California State Personnel Board has announced that applications will be received from citizens throughout the United States for the position of public health nurse in the State Department of Public Health, entrance salary \$150 a month.

Applicant must have license as registered nurse in California and certificate as public health nurse in that state, must have completed course in public health nursing at recognized university. Candidates from other states must submit evidence of application for license and certificate in California.

Applications must be filed by Octo-

ber 1. Forms and information may be obtained from California State Personnel Board office, 1015 L Street, Sacramento, Calif.

POSITIONS AVAILABLE

Physician with either public health training or experience in local health department administration to serve as health director in a county health department in mid-western state. Salary \$4,000 and \$500 travel (flat rate). Well established department with offices in attractive little city of 10,000. Write Box T, Employment Service, A.P.H.A.

Western state department of health will consider applications from physicians to fill four existing vacancies among county health officers, one vacancy in venereal disease control and positions as laboratory technicians. Write Box S, Employment Service, A.P.H.A.

County Public Health Nurses for New Mexico. Must have 4 months' postgraduate instruction under one of the recognized public health nursing courses and 1 year's experience. Must drive and have a car. Address inquiry to State Health Department, Santa Fe, N. M.

PUBLIC HEALTH ENGINEER

Responsible professional public health engineering involving field investigations and office studies in the application of sanitary measures. The more difficult engineering and sanitation field surveys include supervision over public water supplies, sewerage systems and sewage treatment plants and review of plans for same, and promotion and supervision of sanitation programs. Minimum qualifications: Training and experience equivalent to 3 years' civil engineering experience, including 2 years in public health or sanitary engineering; or completion of an aca-

demie year of graduate study and a year's experience in sanitary or public health engineering; and graduation from a college of recognized standing with a major course in civil or sanitary engineering. The salary range is \$205 to \$250 per month depending upon experience. Apply Box E, Employment Service, A.P.H.A.

OTHER VACANCIES

Southwestern state health department seeks 2 physicians for assignment to district health units, personally to conduct several small venereal disease clinics on a rotating schedule. Experience preferred but not required. Salary \$3,000, plus actual travel allowance not to exceed \$1,200. Write Box V, Employment Service, A.P.H.A.

Wanted: Nurse for county health work. Salary \$1,800 per year with travel allowance (additional) of \$500 per year. Address District Health Department 2, West Branch, Mich.

Wanted: Supervisor of generalized public health nursing staff of 6 to 8 nurses. Beginning salary \$175 per month, with opportunity for increase to \$220 and travel expenses. Must be high school graduate, graduate of hospital of 100 beds, and must have at least 1 year's postgraduate study in public health nursing at a recognized institution, and 2 years' experience in general public health nursing under qualified supervision. Apply Box L, Employment Service, A.P.H.A.

The New Mexico State Department of Public Health will consider applications for the position of obstetrical consultant, Maternal and Child Health Division. Address inquiries to the State Department of Public Health, Santa Fe, N. M.

POSITIONS WANTED

ADMINISTRATIVE

Teaching or administrative position desired by physician, aged 48. Experienced teacher in preventive medicine and public health, now employed at prominent medical school; 20 years' experience in municipal health administration and epidemiology. A-491

Physician, B.S., M.D., and M.S.P.H., University of Michigan, aged 35, experienced city-county health administration and as director university student health service. Will consider permanent responsible position offering good income. A-492

Physician with 25 years' full-time experience in public health administration is available for immediate appointment. Moderately hard of hearing; otherwise fully able. Salary \$4,500 or better. A-497

Physician, M.D., C.P.H., aged 47, seeks position in administrative work. Experienced in venereal disease control and industrial medicine. A-485

Physician, aged 47, M.D., Creighton University, M.S.P.H., Michigan, experienced in school health and as director of county health unit, seeks position as ad-

ministrator in state or local health department. A-498

Physician, aged 37, M.D., McGill, D.P.H., Toronto, experienced as health officer and director of public health training, seeks position in administrative work. A-499

WOMEN PHYSICIANS TRAINED IN PUBLIC HEALTH

Woman, aged 34, M.D., University of Basle, Switzerland, M.S.P.H., DeLamar Institute, Columbia University. U. S. citizen. Excellent references. Especially interested in industrial hygiene. A-493

Woman, aged 41, M.D., Columbia University, M.S.P.H., DeLamar Institute, experienced in epidemiology and research, seeks position offering administration experience. A-494

Woman physician, aged 48, M.D., University of Vienna. Excellent European pediatric experience. Seeks position in pediatrics, administration or statistical research. A-495.

Woman physician, M.D., Rush, M.P.H., Michigan, 13 years' experience in school medical service and administrative county health unit, seeks administrative position. New York area preferred. A-500

HEALTH EDUCATION

Woman with master's degree in health education, 12 years' successful experience

in public school and college teaching, administration and research. Will consider position in normal school, public schools, or in official or nonofficial health agencies. Prefers South or East. Available at once. H-501

LABORATORY

Bacteriologist, young man 28, with B.S. in industrial science, experienced in newspaper work, salesmanship and now employed in state department of health laboratory, seeks position as bacteriologist or doing promotional work of public health nature. L-465

MISCELLANEOUS

Veterinary Doctor, M.P.H., University of Pennsylvania, aged 27, with 2 years of practice, seeks position in food, meat, milk or livestock sanitation with state or local health department. Also interested in teaching position with research facilities. M-451

Public Health Nurse with M.A. degree wishes position in health supervision and teaching in college or public school. West preferred. M-452

Administrative Assistant or Health Educator, woman, M.A., 10 years' experience in health agency offices; 7 years' teaching experience, writer on health and other subjects, experienced in independent research, some training in social work, some hospital experience. M-453

Opportunities Available

WANTED—(a) Supervisor; county department of health; competent executive required; central location. (b) College nurse; small infirmary; student health experience desirable; Pacific Northwest. (c) Student health nurse; public health background required; young woman's college; South. (d) Instructor in and supervisor of outpatient maternity nursing; university hospital; baccalaureate degree and 3 years' public health experience required; faculty appointment; most desirable location. (e) Public health nurse; degree or public health certificate required; \$1,800 to \$2,200. (f) Health supervisor; degree and public health experience required; duties consist of supervising health program of student and graduate staff; large hospital; approximately 170 students, 135 graduates; East. (g) Public health nurse; opportunity to become skilled in rural public health nursing; generalized program; Pacific Northwest. (h) Instructor in public health nursing; university medical center; East. (i) School nurse; Chicago area. Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago.

WANTED—(a) County health officer; woman eligible; South. (b) Physician for field position; woman eligible; state department of health; should be effective public speaker; will provide health training after year or so if not trained; Midwest. (c) Student health physician; well organized service; 640 students, 50 faculty; Midwest. (d) City-county health officer; college and industrial town of 26,000; venereal disease clinic operated in connection with public health department; excellent opportunity for developing department; Midwest. (e) County health officer; California. (f) Physician to head department of health and physical education; 900 students; town of 10,000; Midwest. (g) Young woman physician to joint student health department; young women's college; five physicians on staff; East. Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago.

Situations Wanted

Dentist who has specialized in public health is available; D.D.S., university medical school; several years' private practice; year of postgraduate training in public health hygiene with special emphasis on public health dentistry for which he re-

ceived degree of M.S.P.H.; several years, state department of health; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago.

NEWS FROM THE FIELD

THE BRITISH SCENE 1942

*Charles Porter, M.D., Honorary Fellow, American Public Health Association,
Formerly Medical Officer of Health, St. Marylebone, London*

CIVIL defense, which at one time promised to absorb all the energies of all health officers in the United Kingdom (compelling them to organize the evacuating or the reception of evacuees; to perfect arrangements at first aid posts, air raid shelters, gas decontamination stations, and mortuaries; to muster forces of ambulance drivers, etc.), has now settled into place and the routine of public health is coming back into its own again. This pleases most of the service though, as nearly every health officer's annual report tells, staffs are but skeleton and it is only by efforts more or less superhuman that the normal items receive adequate attention.

It is not only staffs that are skeleton. Annual health reports themselves, at the request first of the Ministry of Health and more recently of the Paper Controller, have shrunk and shrunk until they are merely bare bones picked clean of everything that looks like information to the enemy. Very interestingly, and unexpectedly also, the figures in general are extraordinarily good. In spite of all the population have had to suffer at the hands of the enemy; in spite of domestic and what may be described as "domiciliary" upsets, a remarkable toughness and resistance have been shown by people of all ages and all ranks. The infants, for example, whether in the reception areas, where they should have been, or in their own homes, from which in spite of persuasion they have not been evacuated or to which against all advice they have been returned, have adapted

themselves to conditions and have shown no increased mortality or morbidity. In very many cases indeed officers have claimed record low rates in the war years. For England and Wales the infant mortality rate in the March quarter—always, of course, the most deadly in infancy—at 61 per 1,000 births, was the lowest ever recorded for that period.

Not only so; defying what appeared to be a particularly trying winter, babies arrived in larger numbers than for many years to give a birth rate of 15.3. And, having arrived, the babies found themselves in spite of the war or rather perhaps on account of it, in a land flowing, if not with milk and honey, with milk and black-currant juice and rose-hip syrup. Also for them there was a priority of claim on oranges and other things unobtainable by their seniors. Possibly as a drawback there was a chance that their mothers engaged in war work had to leave them for some hours each day. To make up for this, however, nurseries in plenty were provided where care and attention and affection entirely motherly were at their disposal. On the whole, therefore, it was not so bad a thing to be a wartime baby as might be supposed.

The school children and the pre-school children also have not found themselves too badly off. Certain fears on their account were of course entertained. It was thought, for example, that infectious disease rates would go up. Dread on this account, however, has proved to be almost unfounded. More interesting still, over and over

again in areas where enemy activity has been marked, it is recorded of the children that close examination has failed to reveal evidence of mental or physical disturbance. Frequently also it is noted that nutrition has not suffered noticeably either. One condition that has assumed proportions causing anxiety amongst adults as well as children is scabies. To this, and methods of dealing with it close attention is being given.

Because of fear of typhus fever, a disease from which this country for long has been free, lice have come to assume even more importance than usual. In most areas active steps have been taken to prevent infestation in air raid shelters and to provide for disinfection if necessary. In addition immunization against the infection is on offer and teams consisting of medical and other officers have been formed and are being trained to deal with the disease should it appear.

Mention may also be made of the fact that both in England and Scotland the big drive initiated some months ago to induce parents to take advantage of the immunizing procedure in the case of diphtheria has begun to show results. In Scotland particularly these have been striking. Here reports show that no fewer than two-thirds of the child population have been dealt with and that, whereas amongst the immunized there was one death only, amongst the non-immunized during the same period no fewer than 418 deaths occurred.

Not unexpectedly—having regard to what happened in the war of 1914–1918—tuberculosis has shown a tendency to increase, especially in the case of women. Curiously enough, however, there has been an increase in the case of children under 10. In this group in England and Wales the deaths in 1940 exceeded those in 1939 by over 750, nearly 500 being due to meningitis.

The need for getting together for

the purpose of discussing such occurrences and the steps that could and should be taken to deal with them has been greatly felt by the health service. Congresses and conventions on pre-war lines being out of the question, there was a falling back upon area and branch conferences and meetings. By reviving the so-called "Sessional Meetings" which had been abandoned at the outbreak of war, the Royal Sanitary Institute has rendered most valuable aid in this connection. These meetings in the ordinary way are held at intervals of six or eight weeks at various centers; one or two perhaps in London, the others, at the invitation of the municipality, in places such as Newcastle, Cardiff, Portsmouth, etc. The meetings extend over one or two days—Friday and Saturday, or Saturday alone. They prove very attractive, authorities in surrounding districts sending two or more of their number with the health officers to take part in and report upon the proceedings.

Though there is excellent reason for meetings of this sort, the meeting habit as a matter of fact has shown a tendency to increase. Apart from the Government which, of necessity, must give consideration to what might and should happen after the war is over, all kinds of bodies seem to have felt it incumbent upon them to go into questions affecting "Postwar reconstruction." After the war of 1914–1918 heroes, though promised homes fit to live in, did not actually receive them. By getting down to it early, bodies, official and nonofficial, have revealed a determination to achieve better results than those that came after 1918. As a matter of fact these better results will have to be achieved. Apart altogether from construction there is, as many of our American colleagues have seen, very much in the shape of reconstruction to be done. In one district alone there are 32,000 houses that will have to be recon-

structed or replaced, that being the number, out of a total of 36,000, that were damaged, badly damaged, or demolished.

In spite of such things, however, the people carry on bravely and, as is the habit here, even gaily. Indeed, in spite of the many sometimes agonizing blows received, there is an astonishing amount of gaiety apparent. Notoriously, of course, the Britisher grumbles, but so very much of it has something comic, even witty, about it, and rarely is resentment shown.

Rationing and queues and shortages, though a nuisance, are regarded as inevitable, but while there is admiration for the ingenuity of those responsible for the arrangements, for the black marketers and the racketeers, shopkeepers who enjoy saying "no," and restaurateurs, who reduce portions and raise prices, there is nothing but execration.

That the theaters and performances and shows begin and end at hours that make it necessary to eat too late or too early does not seem to affect attendances much. Also though we feel that by depriving us of the railings around our gardens, squares, and parks, the authorities have struck a shrewd blow at our cherished exclusiveness and love of privacy, we put up with it and keep on digging for victory and waging unceasing warfare against the various slugs, bugs, and beetles that appear to imagine that it is their victory we are digging for.

The fact of the matter is we are all

learning the art of "make do" and to appreciate as a certain author points out, that "comfort and discomfort are comparative terms and anything is more comfortable than it might be."

In medical circles what is found rather difficult is the shortage of personnel. American helpers as they arrive seem to be entirely absorbed and become just part of the service, and the call for more continues to be made. In the public health service, on the medical side, the shortage is acute and rapidly becomes worse. Quite early London University School of Hygiene abandoned courses of instruction and other schools have followed suit. That the step was justified is shown by the smallness of the number of entries for the examination for the special diploma.

Subordinate ranks are affected also but comparatively less. Entrants for the health visitors' certificate are fewer than normal but the numbers continue fairly good.

In the case of sanitary inspectors, on account of calling up, staffs certainly have been depleted and the numbers at present taking the examination and qualification one feels cannot entirely compensate. What is to be done to meet the big demand when the war ends is a question that is receiving very serious consideration. In the case of the sanitary inspector, the Royal Sanitary Institute has a scheme in preparation. The situation vis-a-vis the health visitor will also require attention and the matter no doubt is under consideration.

FELLOWSHIPS IN MEDICINE AND PUBLIC HEALTH OFFERED BY THE
COMMONWEALTH FUND OF NEW YORK THROUGH THE
PAN AMERICAN SANITARY BUREAU

THE Commonwealth Fund of New York, a philanthropic foundation established in 1918 by the late Mrs. Stephen V. Harkness, has announced that it is offering through the Pan American Sanitary Bureau fifteen fellowships for one year's study of public health subjects or postgraduate medical courses to properly qualified persons who are citizens of the other American republics. Fellowships in public health will be open to physicians, sanitary officers, technicians, public health nurses, etc. These fellows will be selected through a system of coöperation with medical and health authorities of the different countries concerned, and whenever deemed advisable they will be interviewed by traveling representatives of the Pan American Sanitary Bureau. Each fellowship will provide living

allowances while the holder is in the United States, travel costs, and tuition. Knowledge of the English language will be among the requirements, and also the possession of certain specific qualifications.

The Pan American Sanitary Bureau, the international health agency of the American republics, has been for some time the recognized clearing house for medical and public health fellowships in the United States, nearly 100 Latin Americans now being in the United States under its auspices.

Application blanks giving complete information will be available through the Commonwealth Fund, 41 East 57th Street, New York, N. Y., the Pan American Sanitary Bureau, Washington, D. C.; or chiefs of American Missions in Latin America.

A CHILDREN'S CHARTER IN WAR TIME

Leonard W. Mayo, Chairman of the Children's Bureau Commission on Children in War Time, reporting recently to the Commission, announced a joint Committee on Evacuation of Children established by the Director of the Office of Civilian Defense and the Director of Defense, Health and Welfare Services. Dean Landis, Director of the OCD, is to serve as Chairman and Martha M. Eliot, M.D., has been designated by the Office of Defense, Health and Welfare Services, to serve as Secretary. The joint committee includes in its membership representatives of the Children's Bureau, U. S. Department of Labor, and of the Office of Education, the Public Health Service, and the Social Security Board of the Federal Security Agency.

It has been agreed that the OCD, in coöperation with military authorities,

has the primary responsibility of formulating and executing plans for the evacuation of civilians and that it is the function of the ODHWS to provide for the health, welfare, and education of evacuees.

Among more than 100,000 Japanese aliens and American citizens of Japanese ancestry who have been moved from Pacific Coast military areas under orders of the Secretary of War, it has been found that more than one-quarter of the evacuees are second and third generation children under 15 years of age who are American born citizens.

According to Dr. Mayo there are still many problems to be settled, such as those relating to the relief of congestion through the construction of more adequate housing facilities, the provision of opportunity for self-support, the improvement of facilities for family life and the provision of health and welfare

services, schools and other essential community activities.

According to the report to the commission, there are in 33 states and territories no less than 325 military and industrial areas where urgent health needs of mothers and children are not being met.

Upon recommendation of the state health officers, the Children's Bureau is reserving \$198,000 of the Maternal and Child Health Fund for 1943 as available for grants to the states for providing medical service and hospitalization for the obstetric and pediatric care of wives and infants of men in the military services, according to Dr. Mayo.

INDUSTRIAL HYGIENE PROGRAM

The publication has been announced by the Division of Industrial Hygiene, National Institute of Health, U. S. Public Health Service, Bethesda, Md., of an outline of an industrial hygiene program for use in industry. Chapters include the medical service, the engineering and safety service, welfare services and medical care for non-occupational disability. The pre-placement examination, night work in rotating shift problems, better nutrition in the plant, and health and safety education for workers are also covered. Copies may be secured from the Division of Industrial Hygiene at the National Institute of Health.

INDUSTRIAL HYGIENE FOR FEDERAL EMPLOYEES

The Division of Industrial Hygiene, National Institute of Health, at the request of the Federal Council of Personnel Administration, has completed a survey of the dispensaries and hygiene services in federal departments located in Washington, D. C. For the most part, these dispensaries are established and operated by the departments and bureaus concerned. Of the 85 dispensaries employing 155 nurses it was

found that not more than 20 were under the supervision of a physician. In no government agency was there found a comprehensive program of environmental and personal hygiene and preventive medicine such as is recommended for private industry. The findings were forwarded by the Surgeon General of the Public Health Service to the Council on Personnel Administration in June. The recommendations included a good preplacement examination, including a chest x-ray, tests for syphilis, urinalysis, and other laboratory studies as indicated, treatment of minor medical emergencies, psychiatric consultation, nutrition consultation, elimination of environmental hazards, systematic reporting of absenteeism and the promotion of health education.

BELA SCHICK LECTURES

Science announces that, in honor of Dr. Bela Schick who is retiring after serving for 19 years as head of the Department of Pediatrics at Mt. Sinai Hospital, New York, N. Y., a fund of \$2,000 has been raised by his pupils, associates, and friends to establish the Bela Schick lectures in his honor.

1941 UNITED STATES DEATH RATES

The Bureau of the Census, Washington, has announced that the lowest death rate in the history of the United States registration states was recorded in 1941. The provisional figures show a crude death rate of 10.5 per 1,000 population. The 1940 rate was 10.8, the figure for 1938 and 1939 being 10.6. There were 21,362 fewer deaths in 1941 than in 1940. According to the report, most of the decrease occurred in the rural areas, with leading declines in the District of Columbia, Idaho, and Vermont. The greatest increases in death rates for individual states were in Arizona and Virginia. The total number of deaths for the entire nation for 1941 was 1,395,507.

U. S. INDIAN MEDICAL SERVICE CURTAILED

The Commissioner of Indian Affairs, Washington, has announced that the medical service available for the Navajos will have to be curtailed as a part of the retrenchment growing out of reductions in the appropriations for the work for Indians throughout the country of \$13,000,000. A cut of more than half a million dollars in the budget for the Navajo Reservation will result in the closing of two hospitals at Leupp, Ariz., and Toadlena, N. M.

The position of Medical Director of the Navajo area will be abolished, effective August 15, thus releasing W. W. Peter, M.D., Dr.P.H., for service elsewhere. For the past 8 years Dr. Peter has had supervision of nine hospitals and three tuberculosis sanatoria as well as the oversight of a public health program for 53,000 Navajos. The reason for the present retrenchment is given as war necessity.

CALIFORNIA SOCIAL HYGIENE ASSOCIATION

The California Social Hygiene Association, San Francisco, has announced the appointment of Lawrence Arnstein as Executive Secretary with offices at 45 Second Street, San Francisco, in coöperation with the California Tuberculosis Association. Mr. Arnstein, with long experience in the business field, has for nearly 30 years been a member of the San Francisco Board of Health.

A coöperative plan between the San Francisco City and County authorities, the State of California, and the U. S. Public Health Service, looks toward the development of a so-called "amateur diversion program" which aims at the rehabilitation of younger prostitutes. Psychiatrists connected with the project include Dr. Ernest Lion, Dr. Karl Bowman of the University of California, and others. The California State Board of Health has provided funds to

equip a floor over the venereal disease clinic which is expected to be in operation by the first of September with the services of two psychiatric social workers. Active contacts are under way with labor unions in coöperation with the San Francisco Health Department, and an educational program has been begun.

Among the Board of Directors of the California Social Hygiene Association specially interested in this project are Ray Lyman Wilbur, M.D., President of Stanford University; Walter H. Brown, M.D., Stanford University; Roscoe Chandler, M.D., Dean of Medicine, Stanford University; J. C. Geiger, M.D.; San Francisco Director of Public Health; W. Ford Higby, Secretary of California Tuberculosis Association; Malcolm F. Merrill, M.D., Director of Venereal Disease Control, State Department of Health; Karl F. Meyer, Ph.D., Hooper Foundation, University of California; Langley Porter, M.D., formerly Dean, University of California Medical School; Milton Rose, M.D., Dr.P.H., Medical Director, American Red Cross, Western Division, San Francisco; Chester Rowell, Editor, *San Francisco Chronicle*; William P. Shepard, M.D., Metropolitan Life Insurance Company, San Francisco; Charles Edward Smith, M.D., Professor of Public Health, Stanford University.

DR. HANSON BECOMES FLORIDA STATE HEALTH OFFICER

Governor Spessard L. Holland of Tallahassee has announced the appointment, effective in July, of Henry Hanson, M.D., as State Health Officer for the Florida State Board of Health, with offices in Jacksonville.

Dr. Hanson has for the last several years been a staff member of the Pan American Sanitary Bureau, assigned to various South American countries. He previously served a term as health officer of Florida.

INCUBATOR PLANS AVAILABLE

The Children's Bureau has available a new supply of plans for building two types of incubators and a carrier for premature babies, which were prepared by the National Youth Administration and the Children's Bureau.

If copies have been requested and have not been received an order sent now to the Children's Bureau, U. S. Department of Labor, Washington, D. C., will be filled promptly.

AWARD OF THE GEIGER MEDAL AT
TULANE

The Geiger Medal for an outstanding thesis in the field of public health and sanitation has been awarded to Grace L. Ivanhoe, M.S., for her thesis on "Studies on the Transmission of Amebiasis in a Children's Home in New Orleans."

According to Dr. Ernest Carroll Faust, Professor of Parasitology in the Department of Tropical Medicine at Tulane, the problem involved the epidemiology of amebiasis in an infant home where there had been for more than 10 years a high incidence of amebiasis.

Attempts to eradicate the disease by therapeutic procedures alone had been a complete failure. An intensive study of the contacts of the children was undertaken and the particular dormitory was isolated where the children acquired their infection. Parasites were found widespread in their environment, on clothing, play objects, benches, floors, the water of their wading pool, and on clothing which had been laundered without boiling. Success followed after sterilization of the entire premises with live steam and routine use of anti-amebic therapy.

The Geiger Medal is an award presented to Tulane University, New Orleans, La., by Dr. J. C. Geiger, Health Officer of the City and County of San Francisco.

DR. STEICHEN JOINS MERIT SYSTEM
STAFF

William P. Shepard, M.D., Chairman of the Committee on Professional Education of the American Public Health Association, has announced the appointment of Mary Steichen, M.D., M.S.P.H., as Subject Matter Consultant in Public Health Practice to the Subcommittee on Merit Systems of which George H. Ramsey, M.D., Dr.P.H., is Chairman. Dr. Steichen, who is a graduate in medicine of the University of Rochester, and in public health of the DeLamar Institute of Public Health, Columbia University, has been health officer-in-training under the New York City Department of Health for 2 years. She will aid in the development of tests in various public health fields, supplementing the work in public health nursing carried on by Dorothy Deming, R.N., and the test construction project under Cecil Brolyer.

RESEARCH IN NUTRITION

The Nutrition Foundation, Inc., New York, N. Y., has announced that the research projects approved by the Board in 1942 include the following having a direct relationship to public health: methods for the detection of clinical vitamin deficiencies; quantitative relations of vitamin A intake to bodily store and well-being at different ages; relation of nutrition to dental caries in the monkey; the carotene and vitamin A content of market butters; conservation of vitamins and other nutritive values in dehydrated vegetables; the amino acid requirements of man; survey of the ascorbic acid content of Ontario-grown fruits and vegetables; nutritional deficiencies in the Atlantic region; relation of nutrition to cellular metabolism, with special reference to rheumatic fever and chemotherapy; factors which may alter calcium utilization by the adult man; influence of dietary factors on the healing of bone fractures.

Other projects that primarily advance the frontiers of the science of nutrition were announced as follows: development of bioassays for vitamins and amino acids; thiamin analysis and stability in cereal products; nature and content of pro-vitamin A pigments and content of ascorbic acid in tomatoes; studies of the vitamin B complex with the mouse as an experimental animal; biotin (vitamin H) metabolism in man; protein and vitamin interrelationships; the nutritional significance of biologically available methyl groups for man and various animal species; vitamin content of important plant foods; synthesis and metabolism of nicotinic acid in the rat; fluoride and phosphate metabolism of bones and teeth; metabolic fate of choline; the amino acid content of vegetables; quantitative study of nutrients of mother's milk under specific or known dietary conditions at different states of lactation; copper-containing proteins and their relation to the destruction of specific nutrients; to support the work of the Food and Nutrition Board of the National Research Council in developing and applying the science of nutrition; publication of authoritative reviews.

PUBLIC HEALTH IN HAWAII

M. F. Haralson, M.D., Territorial Commissioner of Public Health, Honolulu, has reported that, "in the interest of public safety and for the good of all persons," it had been decided to require immunization against typhoid fever and smallpox in the civilian population of the entire Territory.

The first military order required the immunization of the rural civilian population residing in the northern section of the Island of Oahu. Subsequent orders extended the area until it embraced all of Oahu, including Honolulu and the outside islands. The orders required vaccination against typhoid and paratyphoid fever of all persons

over the age of 3 years and the vaccination against smallpox of all persons over the age of 6 months unless such persons had been protected against the diseases since January 1, 1941. Provision was made for the exemption and deferral of those actually ill, infirm, aged, crippled, etc.

Immunization against diphtheria was not required by the terms of the military order but the procedure was strongly recommended by the health department.

This program was undertaken by the Board of Health, working in collaboration with the Office of the Department Surgeon, and advantage was taken of the fact that the entire civilian population of the territory had recently been enumerated and registered. Those over the age of 6 had been fingerprinted and issued identification certificates bearing personal data and a registration number. This fact provided a basis for planning and administering the immunization program, provided centers for immunization, permitted the calling in each day of an exact number of persons who could be handled at each center and the identification recorded.

According to Dr. Haralson's report it is believed that this is the first instance in the history of the United States in which compulsory vaccination for both typhoid fever and smallpox has been required of the entire population of a state or territory and it is believed that, for the first time, the vaccination status of every individual residing in a state or territory can be reported.

Dr. Haralson reported that coöperation was exceedingly satisfactory.

During the month of March, 1942, an outbreak of 74 cases of typhoid fever occurred in Honolulu, all but two of which were directly traceable to a cafeteria worker who was identified as a carrier.

ILLINOIS CONFERENCE ON PUBLIC HEALTH TO MEET IN ST. LOUIS

Dr. Roland R. Cross, the Director of the Illinois Department of Public Health, Springfield, has announced that, because the American Public Health Association is this year holding its Annual Meeting in nearby St. Louis, Mo., the Illinois Department of Public Health has arranged as a war measure to hold its 1942 State Conference on Public Health in connection with the national conclave, thus saving busy Illinois health workers the time, expense, and travel that would have been required to attend two separate meetings. All Illinois residents interested in the promotion of public health are invited to attend the state-sponsored Illinois Conference on Monday, October 26, scheduled as a joint meeting with the Illinois Public Health Association, an affiliated society of the American Public Health Association. The preliminary program for the conference includes addresses by Dr. Cross and by Dr. Huntington Williams, Commissioner of Health of Baltimore, Md., and Dr. Henry F. Vaughan, Dean of the School of Public Health, University of Michigan, Ann Arbor.

NATIONAL NURSING COUNCIL FOR WAR SERVICE

The National Nursing Council for War Service has published, with the approval of the Health and Medical Committee of the Office of Defense, Health and Welfare Services, and its Subcommittee on Nursing, and with the approval of the American Red Cross, a booklet entitled "Nurses, to the Colors!" which defines certain priorities in nursing to meet the war emergency.

According to this booklet, which has been released by Elmira B. Wickenden, Executive Secretary of the Council, nurses should serve with the armed forces if they are single, under 40, and are:

- (1) doing private duty
- (2) on a hospital's general staff
- (3) a head nurse not essential for teaching or supervision
- (4) a public health nurse not essential for maintaining minimum civilian health service in any given community
- (5) in a non-nursing position
- (6) an office nurse.

According to the Council, nurses should serve at home if they have positions:

- (1) in a hospital which has a school of nursing as
 - (a) administrator in a key position
 - (b) instructor
 - (c) supervisor
 - (d) head nurse, in a position related to teaching or supervision
- (2) in a hospital without a school of nursing, as
 - (a) administrator
 - (b) supervisor
- (3) in a public health agency, as
 - (a) administrator
 - (b) teacher and supervisor
 - (c) Staff nurse essential for maintaining minimum civilian health services in any given community
 - (d) industrial nurse

Nurses who are eligible and wish to enter military service should enroll in the First Reserve of the American Red Cross Nursing Service for assignment to the Army Nurse Corps or the Navy Nurse Corps. Further information is available from the National Nursing Council for War Service, 1790 Broadway, New York, N. Y.

BUENOS AIRES SOCIETY FOR HISTORY OF MEDICINE

THE Society for the History of Medicine at Buenos Aires, Argentina, has elected as honorary members of the Society Esmond R. Long, M.D., F.A.P.H.A., Professor of Pathology at the University of Pennsylvania and Director of the laboratories at the Henry Phipps Institute, Philadelphia, and Henry E. Sigerist, M.D., Director of the Institute of the History of Medicine at Johns Hopkins University.

POLIOMYELITIS STUDY GRANT AWARDED TO JOHNS HOPKINS

The National Foundation for Infantile Paralysis, Inc., New York, N. Y., announced on July 13 that it had made a grant of \$300,000 payable over a period of 5 years to the Johns Hopkins University, Baltimore, for the establishment of a Center for the Study of Infantile Paralysis and Related Viruses.

According to the Foundation there is a need for units in which all the problems of poliomyelitis can be studied on a comprehensive scale and on a long-time basis to supplement the separate research grants now provided by the Foundation in leading institutions throughout the country.

The work at the Center will be under the direction of Kenneth F. Maxcy, M.D., Dr.P.H., Professor of Epidemiology in the University School of Hygiene and Public Health, who will be assisted by a group of scientists, including Howard A. Howe, M.D., David Bodian, M.D., and Robert C. Mellors, a biochemist from Western Reserve University. It is expected that other appointments to the staff will be made.

Laboratory space and facilities have been provided and the new grant will permit the investigators to carry on studies in the field as well as in the laboratory as opportunities may be presented. The ultimate objective is said to be the attainment of a more complete understanding of the spread of the poliomyelitis virus, not only within the human body but in the community. The project will involve epidemiologists, biologists, serologists, neurologists, and chemists.

A.M.A. PROVIDES FOR OBSERVERS OF HEALTH EDUCATION WORK

W. W. Bauer, M.D., Director of the Bureau of Health Education, American Medical Association, Chicago, has announced that the Trustees of the American Medical Association have author-

ized the Bureau of Health Education to accept postgraduate students, not more than two at a time, for two weeks or less of observation, demonstration, and participation in health education work as conducted by the Bureau of Health Education. Students would have no fees or tuition to pay and would make their own arrangements for maintenance.

ARMY JAUNDICE TRACED TO YELLOW FEVER VACCINE

Secretary of War Stimson said in Washington on July 24 that between January 1 and July 4, 1942, 28,585 cases of jaundice had developed among Army men, apparently as the result of inoculation with yellow fever vaccine. There had been 62 deaths from jaundice, or a case fatality rate of one in 461 cases. He announced that the Surgeon General of the Army had made a change in the form of yellow fever vaccine now used with the hope that it will eliminate the difficulty.

According to Mr. Stimson, the peak of the epidemic was apparently reached during the week ending June 20, when 2,997 hospital cases were reported; 2,575 cases were reported for the week ending July 4. Of the total cases 24,057 occurred at home, the remainder abroad.

It was explained that, because of the long period of incubation following inoculation before the jaundice developed, it had been particularly difficult to study the outbreaks. Members of an Army commission investigating the disease have recently stated that the jaundice was traceable to only a few lots of the vaccine and that it was almost certainly not a form of yellow fever which, under present conditions, could spread from person to person. The possibility has been mentioned that an extraneous virus may have entered certain lots of the vaccine through the supposedly normal human serum which is a component of the finished product.

ILLINOIS ESTABLISHES THREE DEFENSE ZONE COUNTY HEALTH DEPARTMENTS

Dr. Roland R. Cross, Director of the Illinois Department of Public Health, has announced that, although Illinois has no law at present to enable all interested counties to provide adequate official county health services locally, state-subsidized full-time health departments, set up in defense zones under the emergency legislation now available, are already in action in three counties. The Lawrence County Health Department has been set up at Lawrenceville under Dr. D. F. Rawlings. The Lee County Health Unit has been set up at Dixon with Dr. A. L. Barbakoff, and the Williamson County Health Department headed by Dr. M. E. Cosand is established at Herrin.

In addition, Cook County, which is also a health defense area, has a full-time county health unit established in 1940 as a section of the County Bureau of Public Welfare and directed by Dr. E. A. Piszczek.

According to Dr. Cross, many of the remaining 17 counties which have been named as defense zones for public health purposes have expressed interest in developing effective local health services with state aid, and it is expected that a new defense zone health department may be opened in Will County shortly with Dr. C. A. Z. Sharp in charge. This leaves 81 Illinois counties still without power under existing law to set up county health services, there being 16 other defense counties now eligible for state aid.

MASSACHUSETTS COMMITTEE ON PUBLIC SAFETY

The Massachusetts Committee on Public Safety, which has headquarters at 18 Tremont Street, Boston, and of which J. W. Farley is Executive Director, has a Health Executive Committee of which Professor Curtis M. Hilliard of Simmons College is the Director. Other

members include Manfred Bowditch, Ernest M. Morris, M.D., Sophie C. Nelson, R.N., Maurice E. Peters, D.M.D., Alton S. Pope, M.D., Arthur J. Strawson, Douglas A. Thom, M.D., James O. Wails, M.D., and Ruth White.

TUBERCULOSIS CONTROL AS A WAR MEASURE

To prevent an increase in tuberculosis deaths, such as occurred in all countries during the last World War, the Public Health Service has begun x-ray examinations of its entire staff including commissioned officers and Civil Service personnel, both at headquarters and field stations.

The examinations are being conducted by the Tuberculosis Control Unit of the States Relations Division in cooperation with the Division of Industrial Hygiene, National Institute of Health. Surgeon General Thomas Parran said in announcing the program: "The armed forces have already undertaken x-ray examination of all enlisted men entering the services. The next specific undertaking should be the examination of all industrial employees, and an annual follow-up in certain groups of workers—all if possible." He also recommended that the men in the armed forces be reexamined at the end of the war, before they reënter civilian life. Personnel of the U. S. Public Health Service are to be reëxamined annually during the duration of the emergency.

NURSERY CARE STUDY IN NEW YORK CITY

Mayor LaGuardia has announced that Leona Baumgartner, Ph.D., M.D., Director of the Bureau of Child Hygiene of the New York City Department of Health, has been designated to make a study of the existing facilities for nursery care in New York City. This is at the request of the Mayor's Committee for War Time Care of Children. Frank J. O'Brien, Associate

Superintendent of the Department of Education, is responsible for the standards for nursery schools.

NEW YORK STATE HEALTH OFFICERS ASSOCIATION

The New York State Health Officers Association at its meeting June 23 in Saratoga elected the following officers for the coming year:

President—William Runcie, M.D., Freeport.

First Vice-President—J. R. MacElroy, M.D., Jonesville.

Second Vice-President—G. E. Sanders, M.D., Dewey.

Third Vice-President—Burdge P. MacLean, M.D., Huntington.

Secretary—R. H. Wilcox, M.D., Tonawanda.

Treasurer—H. B. Doust, M.D., Syracuse.

NEW YORK STATE ASSOCIATION OF SCHOOL PHYSICIANS

At its meeting on June 22 in Saratoga, the New York State Association of School Physicians elected John E. Burke, M.D., Schenectady, to the office of President for the coming year.

Edgar Bieber, M.D., Dunkirk, was reelected *Vice-President*.

C. Adele Brown, M.D., Oswego, was reelected *Secretary-Treasurer*.

William E. Ayling, M.D., Syracuse, was elected a member of the Executive Committee as were Clarence A. Greenleaf, M.D., Olean, Lewis Wade Heizer, M.D., Watertown, and Michael Levitan, M.D., Rome.

PERSONALS

Central States

MAINE C. ANDERSEN, M.D., of Omaha, Neb., has been appointed Director of the Health Service at the University of Omaha, effective September 1. He succeeds JOHN C. SHARPE, M.D., of Omaha, resigned.

F. C. BEELMAN, M.D.,† formerly Director of the Division of Tuberculosis Control, and since October,

1941, acting Secretary and Executive Officer of the Kansas State Board of Health, Topeka, was appointed as Secretary and Executive Officer at the June 25 board meeting, taking the place of F. P. HELM, M.D.,‡ who was given leave of absence last fall for a year's postgraduate work in public health at the University of Michigan. Dr. Helm received his master's degree in June, was given a reserve commission as Surgeon in the U. S. Public Health Service, and has been detailed to the State of Texas as Deputy State Emergency Medical Service Chief, OCD.

CLAYTON C. BENJAMIN, M.D., M.S. P.H.‡ of Munsing, Mich., has been appointed in charge of the new County-City Health Unit, with headquarters in Ludington.

RICHARD F. BOYD, M.D., M.P.H.,* has been announced as Chief of the Division of Local Health Administration, by Roland R. Cross, M.D.,‡ Director of the Department of Public Health, State of Illinois, Springfield, effective July 1. Dr. Boyd has been serving as Acting Chief following the death of MARVIN F. HAYGOOD, M.D., M.P.H.,‡ who was to have taken office on July 1.

ERROL V. BRUMBAUGH, M.D., of Milwaukee, Wis., has been appointed Health Commissioner of West Allis, filling the vacancy that occurred when FRANK H. RUSSELL, M.D., of West Allis, resigned recently.

DAN H. CAMPBELL, Ph.D., Assistant Professor of Immunology, Department of Bacteriology and Parasitology, Division of Biological Sciences, University of Chicago, has accepted an appointment at the California Institute of Technology, Pasadena, as Assistant Professor of Immunochemistry.

PAUL T. COOK, M.D., has been made District Health Officer of six counties with headquarters in Valley

* Fellow A.P.H.A.

† Member A.P.H.A.

City, N. D., succeeding ROBERT G. WHITE, M.D.,* who was transferred to Bismarck.

GERRY B. DUDLEY, M.D., of Charleston, Ill., has been appointed a member of the Board of Public Health advisers in the Illinois State Department of Public Health, succeeding CLIFFORD U. COLLINS, M.D., of Peoria, Chairman, who resigned.

LYMAN D. EATON, M.D., of Indianapolis, Ind., has been named Director of the District Health Unit at Princeton, covering Gibson, Pike, Posey, and Warrick Counties.

GREGORY L. ENDRES, M.D.† of Omaha, Neb., has been named Director of the newly created Dodge-Saunders Counties Health Unit.

F. K. HARDER, M.D., M.P.H.,* Assistant Commissioner of Health in Cincinnati, Ohio, has resigned to accept the position of Health Director in the City of Greensboro, N. C.

BARBARA A. HEWELL, M.D., Pediatric Coördinator of the Cincinnati Anti-Tuberculosis League, Cincinnati, Ohio, has resigned to become Specialist in Child Hygiene in the Division of Research in Child Development in the U. S. Children's Bureau, Washington, D. C.

H. L. HIEBERT, M.D., is the new Director of Tuberculosis Control for the Kansas State Board of Health, Topeka, taking the place of F. C. BEELMAN, M.D.,† who was appointed Secretary and Executive Officer of the department. Dr. Hiebert formerly was on the staff of the Minnesota State Tuberculosis Sanatorium.

FRANCIS R. HOLDEN, Ph.D.,† has been appointed Industrial Hygienist on the staff of the Industrial Hygiene Foundation at the Mellon Institute, Pittsburgh, Pa. Following his graduation from Hobart College at the University of Cincinnati, Dr. Holden has

been connected with the Industrial Health Conservancy Laboratories in Detroit, and the Safety Department of the Pittsburgh Plate Glass Company.

DR. DARLINGTON FRANK HOLTMAN, Instructor in Bacteriology at Ohio State University, has been appointed Assistant Professor of Bacteriology in the Western Reserve University School of Medicine, Cleveland. Dr. Holtman assumed his new duties on July 1.

GLENN V. HOUGH, M.D., of Milwaukee, Wis., has been appointed Medical Director of the Marathon County Health Unit, Wis., succeeding ERNEST NEWMAN, M.D.,† of Wausau, who has a similar position at Las Vegas, Nev.

NICHOLAS A. JAMES, M.D., of Tell City, Ind., is the new Health Officer of Perry County, Ky., it is reported.

EVERETT A. KING, M.D.,† formerly of Fort Wayne, Ind., now of the U. S. Public Health Service, has taken over the work of the Health Office in the Tri-County Unit composed of Hancock, Breckenridge, and Meade Counties, Kentucky.

FREDERICK P. KNAUF, M.D., of Kiel, Wis., has been appointed City Health Officer of Kiel, to fill the unexpired term of the late GEORGE MATHES, M.D., who resigned shortly before his death, February 19, after holding the position since 1900.

PAUL A. LINDQUIST, M.D., M.S.P.H.,† of Manistee, Mich., has resigned as Medical Director of the Mason-Manistee-Benzie County Health Unit, to accept a similar position of the new County-City Health Unit being established in Monroe County.

HOMER E. LINE, M.D., of Chili, Ind., has been appointed Health Officer of Miami County.

MILTON E. PARKER,* Manager of Production, Beatrice Creamery Company, Chicago, Ill., has been appointed

* Fellow A.P.H.A.

† Member A.P.H.A.

Adviser to the Resources Division, Office of the Quartermaster General, War Department, Washington, D. C., on production and quality control of dairy products.

R. H. RIEDEL, M.D., Director of the Division of Venereal Disease Control, on leave of absence from the Kansas State Board of Health, Topeka, is on active duty with the Army, having been a reserve officer since 1928. He has a Captain's commission and is on duty at Camp Carson, Colorado Springs, Colo.

H. R. ROSS, M.D.,† resigned his position as Director of the Child Hygiene Division of the Kansas State Board of Health, Topeka, and has been appointed as Medical Consultant to the department. FRED L. MAYES, M.D., Assistant Director of the Division, succeeds Dr. Ross.

HENRY C. SCHOLER, M.D., has been named Health Officer of Monmouth, Ill., succeeding JAMES W. FIROVED, M.D., who resigned to enter the medical corps of the Navy.

JOHN D. WINEBRENNER, M.D.,‡ of Princeton, Ind., has been named Director of the newly created District Health Department No. 5, with offices in Columbus. The District includes Bartholomew, Johnson, Shelby, Jackson, and Decatur Counties.

Eastern States

GEORGE P. BERRY, M.D.,* Professor of Bacteriology and Assistant Dean of the University of Rochester School of Medicine, Rochester, N. Y., received one of the 9 fellowships awarded by the City of Rochester for distinguished service at special ceremonies on May 22.

G. DONALD BUCKNER, S.B.,‡ Health Officer of Needham, Mass., has been appointed Executive Secretary of the

Southern Worcester County Health Association, Mass.

FRANK A. CALDERONE, M.D., M.P.H.,* has been appointed Secretary of the New York City Department of Health, having been District Health Officer of the lower East Side Health District, New York City, for several years.

HENRY D. CHADWICK, M.D.,* former Commissioner of Health, Massachusetts State Department of Public Health, has retired as Director of the Middlesex County Sanatorium and is now giving full time as Medical Director and Superintendent of the Cambridge Sanatorium, Cambridge, Mass. Dr. Chadwick was recently chosen President of the Massachusetts Tuberculosis League.

DR. RENÉ JULES DUBOS, member of the Rockefeller Institute for Medical Research, has been announced by Harvard University as the George Fabian Professor of Comparative Pathology and Professor of Tropical Medicine at the Harvard Medical School, Boston. He succeeds Dr. ERNEST E. TYZZER, who becomes Professor Emeritus.

DR. J. I. FEINMAN has been appointed a member of the teaching staff in Pharmacology, at the Philadelphia College of Pharmacy and Science, Philadelphia, Pa., as announced by Dr. Ivor Griffith, President of the College. Dr. Feinman, who graduated from the institution in 1928 and later received his medical degree, takes the place of Dr. E. A. MULLEN, now on leave of absence and serving as Commander in the United States Navy.

ELIZABETH M. FINIGAN, Health Investigator for Institutions, Division of Communicable Diseases, New York State Department of Health, retired on May 1, after 29 years' service.

WILLIAM A. HOLLA, M.D.,‡ formerly Deputy Commissioner of Health in

* Fellow A.P.H.A.

† Member A.P.H.A.

the Westchester County Department of Health, White Plains, N. Y., was appointed on July 28 as Commissioner of Health in the department, succeeding GEORGE H. RAMSEY, M.D., DR.P.H.,* who recently resigned for reasons of health. Dr. Holla has been a member of the county staff since 1930.

Western States

LEONARD A. DEWEY, M.D., C.P.H.,† of Seattle, Wash., Chief of the Division of Epidemiology and Venereal Disease Control, Washington State Department of Health, is on leave of absence to the U. S. Army. Dr. Dewey has been placed in charge of venereal disease control in the Eighth Corps Area, with headquarters in San Antonio, Tex.

WILLIAM A. POWELL, M.D.,† of Martinez, Calif., has been placed in charge of the administration of health affairs of the cities of Antioch, Calif., and Pittsburgh, Calif., recently trans-

ferred to the Contra Costa County Health Department. FRED P. NEVIUS, M.D., has been serving as Health Officer of Antioch, and GEORGE C. KELSO, M.D., as Health Officer of Pittsburgh. With the exception of the cities of Richmond and El Cerrito, nearly all of Contra Costa County is now under the jurisdiction of the county health unit.

Puerto Rico

EDUARDO GARRIDO MORALES, M.D., DR.P.H.,* who has been Commissioner of Health of Puerto Rico since 1933, retired as Commissioner on June 26, and on July 1 went on duty as Major in the Medical Corps, U. S. Army, at Fort Buchanan, San Juan, P. R. Dr. Garrido has been assigned a study of the malaria problem and is Medical Inspector of the camp. Dr. Garrido is currently a Vice President of the American Public Health Association.

Epidemiologic Implications of Wartime Population Shifts*

KENNETH F. MAXCY, M.D., DR.P.H., F.A.P.H.A.

*Professor of Epidemiology, School of Hygiene and Public Health,
The Johns Hopkins University, Baltimore, Md.*

IT is impossible to discuss at this time epidemiological implications of the convulsive shifts of population precipitated by total warfare in Europe and Asia. Adequate information is not available. From meager reports which have filtered through the censored press, it can be inferred that pestilential diseases—typhus, cholera, malaria, dysentery—have taken a tremendous toll of military and civilian populations in the devastated and impoverished countries which have been sucked into the maelstrom. The end will not come with cessation of hostilities. It will wait upon reconstruction of stabilized governments and communities.

Our concern on this occasion is with the danger to our own people from infectious disease as a result of disturbances due to the war. The United States has been preparing for this struggle with gradually increasing tempo during the past two years. Cities on the North American continent have not yet experienced the horrors of being

bombed and invaded. Nevertheless, great changes in the distribution of population and conditions of living have already taken place and are continuing. These changes are brought about by movements of three different kinds: (1) by migration of able-bodied men of military age from every walk of life and section of the country into induction and training centers of the Army and Navy; (2) by evacuation of civilian population groups from areas of military importance; and (3) by migration of workers and their families to boom towns adjacent to military and industrial establishments. Each has its peculiar epidemiological implications.

With regard to the first, the increased risk from infectious disease to recruits is a phenomenon well known since the dawn of history in all military undertakings. It is the primary concern of the medical and sanitary officers of the Army and the Navy. For the purposes of this discussion it suffices to state that in the mobilization of the armed forces of the United States for this war the experience up to the present has been far more favorable than was anticipated

* Read before the Western Branch American Public Health Association at the Thirteenth Annual Meeting, Seattle, Wash., May 27, 1942.

on the basis of what happened in 1917-1918. With the construction of vast training establishments and the organization of medical facilities rapidly approaching completion, the period of greatest danger from the common infectious diseases would seem to be past. No serious epidemic has yet affected an Army and Navy of more than five million men.

With regard to the second, the evacuation of civil populations from limited areas for military reasons, there has been little experience so far. About 40,000 Japanese families are in process of being removed from the Pacific coastal area and re-settled in the interior of the country. The acquisition of land for military establishments and for training purposes, has required the dispossession and removal of some 10,000 native American families from limited areas widely distributed over the country but particularly in the southern states. These movements, however, are insignificant in comparison with what would happen if the threat of bombing and invasion became imminent. Such an eventuality must be considered.

Some idea of the epidemiologic implications of mass evacuations can be gained from an examination of what has happened in England. Even before the war actually began, the threat to civil communities was realized and plans were formulated. Air raid precautions demanded the evacuation of mothers and children from large industrial cities to the small towns and rural districts. Naturally, considerable anxiety was expressed that this movement might precipitate epidemics of diphtheria, scarlet fever, cerebrospinal meningitis, poliomyelitis, or other dangerous acute infectious disease. The following is an excerpt from an editorial which appeared in the *Lancet*,¹ just after hostilities had begun between Germany and England:

The complications of evacuation cannot yet be foreseen. In the hospitals they seem likely to amount to no more than inconveniences. Among the children the risk of infection cannot be denied. Children from crowded cities, which may be considered as permanent epidemic centres of the common infectious diseases, are carrying specific organisms into rural districts which may be, but often are not, permanent epidemic areas for those same organisms. The result will depend not so much on whence the emigrants came as on where they have gone, and the risk, where there is any, is much less to the evacuees than to those on whom they are billeted. The transference from one place to another will not necessarily disturb the epidemic equilibrium provided there is no overcrowding and the two places are in a similar epidemic state. Thus, if Portsmouth is evacuated into Bournemouth without overcrowding, Bournemouth has nothing to fear—a comparable migration takes place every year at holiday time and nothing usually happens. Where the children are sent to small circumscribed towns such as Ipswich, the effect may be different, for if such a town has been free from any one of the endemic infections for some time the immunity of the residents will be low and the risk of infection correspondingly high. Town children sent to isolated rural districts may then be expected to set up epidemic situations among the native population, severe if there is much increase in the population density, troublesome and lingering if the newcomers are well scattered. The risks of diseases not spread by droplets will depend mainly on the state of sanitation, and here again the sparsely populated rural district is the most likely to suffer.

In addition to this editorial there were a series of letters addressed to the Editor of the *Medical Officer*,² a journal for medical men in the government and municipal services, predicting that unless proper precautions were taken, or even in spite of precautions, the evacuation would precipitate a considerable increase in the incidence of infectious diseases.

The Air Raid Precautions Plan divided England and Wales into three types of areas:

- (1) Evacuation Areas—Whole cities or zones in certain cities from which selected groups of the population were to be moved

- (2) Reception Areas—Small towns and rural districts into which these groups were temporarily billeted
- (3) Neutral Areas—Those which were left relatively undisturbed

During the first week of September, 1939, when war was imminent, 1,270,000 mothers, children, and cripples were evacuated—including in the number three-quarters of a million school children—truly a mass migration. The school population in the evacuated areas decreased by approximately three-eighths, and that of the reception areas was increased by about one-third. Hundreds of thousands of rural homes had new inmates; many day, special, and nursery schools became residential schools. Overcrowding of living conditions was inevitable. Pressure of time did not permit many of the precautionary measures which had been thought necessary.

What effect this mass evacuation had upon the morbidity and mortality rates of England and Wales is still not entirely clear. Under the conditions which prevail, it is impossible to maintain undisturbed the level of completeness of reporting. The size and character of the shifting populations at risk in different geographic areas cannot be enumerated, but only roughly estimated. Pressure of war activity prevents field studies. Only crude analyses can be made. Some idea of what happened can be obtained from a few reports which have been published.

During the four months immediately following the evacuation from London, according to Glover,³ the incidence of diphtheria and scarlet fever *decreased* two-thirds and of poliomyelitis one-third, as compared with the same quarter in the previous year. The deaths from scarlet fever were 27 per cent *less*; from diphtheria, 16 per cent *less*; from diarrhea and enteritis under 2 years of age, 27 per cent *less*. The experience with all of the other com-

mon communicable diseases was similarly favorable, and there were no epidemics of unusual infections.

More recently Stocks⁴ has analyzed this experience in more detail, extending the observations through the following year, to the end of 1940. Using official morbidity reports and making certain assumptions with regard to the changes in the population census of the affected areas, he drew two broad inferences: (1) Removal of some 30 per cent of the children under 15 from evacuation towns, coupled with closure of the schools, was followed by a fall of 40 per cent or more in the rate of diphtheria *among the children who remained*, compared with (a fall of) 9 per cent in the neutral areas, by the first quarter of 1940. (2) Influx of children drawn from these towns *to the reception areas*, with consequent increase in their population at ages under 15 by about 30 per cent, was followed by an immediate rise of diphtheria *among the native children* amounting to 60 or 70 per cent, as measured by notifications, but the rate in the whole population of children in these areas (visitor and native) *declined* again within 6 months to its original level. The effect upon the scarlet fever rate was similar but more lasting.

The data upon which Stocks bases his inferences are questionable but, granting their validity, the effect of this mass evacuation upon the increased incidence of the common communicable diseases among the native populations fell happily short of the predictions and there have been no unusual epidemics of serious magnitude.

In the United States it has been the *third* kind of population movement which has been of importance up to the present time—the *migration of labor*. The movement of people in search of gold, money, and work is not a new phenomenon in this country, particularly in the north central and western

states, but this war has brought about a tremendous acceleration and changed the direction of the currents. The direction of flow is the reverse of that which has been discussed in connection with the evacuation of military areas. It is from country to city, from farming to industrial communities, from scattered to crowded living conditions. Employment services estimate that 600,000 workers will leave the farm in 1942. Thus, in a sense, the *rural districts have become evacuation areas and certain towns and cities have become reception areas.*

Boom towns are not a new phenomenon in the United States, especially in the West, but they have been created during the past two years at a rate that is staggering even to the miracle builders of Hollywood. With the amazingly rapid construction and expansion of military establishments and of manufacturing plants all over the country, peaceful villages have been converted into bustling centers of activity. New towns have sprung up almost overnight. Great stabilized cities and their environs have become whirlpools of human exchange. Many have doubled their populations in the past two years. An increase of 25 to 50 per cent in the total number of employables is not unusual. It is important to note that the movement has been one of *adults* to a greater extent than of children. Some workers have brought their families with them; others have left their children at home in care of relatives.

The migratory war workers have been living in tents, trailers, dormitories, barracks, warehouses, basements, and attics. Families have shared homes, apartments, even beds. Crowding in many areas has become intense. Provisions for more adequate housing are going forward rapidly, but some time must elapse before the shortage is overcome.

What are the epidemiologic implications of such situations?

An experience to which I would like to direct attention is that of Halifax,⁵ Nova Scotia. Before the beginning of hostilities, this was a relatively unimportant center of commerce with a stabilized population of about 60,000. With the opening of war in 1938, as in 1917-1918, it became an exceedingly important port. The civilian population increased rapidly with the arrival of thousands of workers and their families. The military garrison was greatly strengthened. There was a constant stream of transients with the arrival and departure of convoys. The epidemiologic implications are evident—crowding, a shifting immunity status, and the possibility of introduction of new strains of parasitic microorganisms from Europe or elsewhere.

For ten years previous to the war, diphtheria had prevailed in that city endemically at a low level. There had been no active campaign to immunize the child population artificially. Schick surveys made in 1940-1941 indicated that 80 per cent of selected groups of adults, as well as of the children, were susceptible.

In September, 1940, cases of unusual severity appeared. Apparently a new and virulent strain of *Corynebacterium diphtheriae* had been introduced. The number of cases reported rose rapidly to reach twenty times the expected incidence during the next three months, attacking adults even more frequently than children. In the civilian population 588 cases were reported, and 303 cases occurred in the military forces. As a result of aggressive measures by the health authorities and medical profession, the epidemic declined somewhat but the disease continued to prevail at a high level throughout the following year and indeed up to the present time. During the same period there have been reported in this city some 600 cases of

scarlet fever and more than 100 cases of epidemic meningitis. Since early in the current year the situation has improved.

This exemplifies the experience of a city in which the epidemiologically expected happened. By way of contrast, I should like to refer to that of a similar urban industrial maritime situation in which it has not.

Previous to the beginning of war preparation, the combined population of the Norfolk-Newport News (Va.) area amounted to about 350,000. With the development of industrial, military, and naval establishments, it has become one of the most important centers on the coast. In two years the population in this area has been almost doubled. Epidemic potentialities have developed similar to those noted for Halifax so far as the housing shortage, crowded living conditions, changing immunity status, and the constant mixing of transient and native populations are concerned. In addition, there has been an acute water shortage. Rationing of water has been necessary for some months, and relief through bringing in a new supply is not expected until the latter part of the current year. In spite of these conditions, up to the present time no significant increase in the infectious diseases has been reported.

The experience of the Norfolk-Newport News area is not unusual. In many other cities and towns conditions which might be classified as epidemiologically dangerous have developed. The surprising fact is that, in spite of the crowding of people into these reception areas and the disturbance of living conditions during the past two years, there has been little, if any, increase in the incidence of infectious disease. For this increase to be sufficiently great in a limited population group and time interval to merit recognition as an "epidemic" requires the fortuitous coincidence of a complex mosaic of fac-

tors, only a few of which are known and many a matter of speculation. This is the hazard of epidemiological prediction.

By way of explaining the unexpectedly favorable experience of both civil and military populations thus far, certain generalizations deserve consideration. The population shifts have occurred with gradually accelerating tempo. There have been as yet no convulsive evacuations such as those which occurred when the countries of Europe were engulfed in war with lightning-like rapidity. The start was made from a position more favorable than has ever been realized before by any great nation in the health and welfare of its people. This country has been realizing dividends on the last quarter-century of intensive public health organization. For example, the conquest of intestinal infections, especially typhoid and dysentery, by environmental sanitation has depleted the human reservoir of infection. The frequency of healthy carriers of intestinal pathogens per unit of population has greatly decreased. The risk from drinking a public water supply contaminated with human sewage is by no means as great as it was. The public, and those who plan for the public, have been educated and are aware as no people previously have been of the fundamental necessity of maintaining public health and sanitary safeguards. Artificial immunization against smallpox, diphtheria, and typhoid fever protect a far larger proportion of the people than before. The venereal infections, gonorrhea and syphilis, have received extensive attention and constitute a special problem which need not be discussed here.

There remain, however, certain respiratory infections whose spread cannot be prevented and against which there is available no means of artificial immunization, as those caused by viruses such as measles, chickenpox, mumps, and the influenza group, and

by bacteria such as pneumococci, hemolytic streptococci (Group A), and meningococci. These thrive where humanity is crowded together. Is the absence of epidemics from these infections among adult populations temporary and fortuitous, or due to factors which are of a more or less permanent character? If the latter, is it due to (a) earlier and more widespread acquisition of immunity to the prevailing strains through clinical or subclinical attack, (b) conditions of living and of personal hygiene which are less favorable to parasitic propagation, (c) some change in the prevailing strains modified in the direction of lower pathogenicity, or (d) some combination of those factors?

With regard to the first hypothesis, it is notable that since the World War of 1917-1918, with the advent of the family automobile, extension of good roads, auto busses and aeroplanes, and such institutions as the "consolidated school" and the "movie," there has been a remarkable change in the frequency and range of human contacts in this country. In the modern United States few communities can any longer be considered isolated in any real sense of the word. Exposure to common infections must be at an earlier age and relatively fewer persons escape attack in childhood.

Some indication that such a change is actually taking place is suggested by a statistical analysis of the age distribution of reported cases of measles in Maryland. Measles is an example of a common infection to which everyone is exposed sooner or later. To compensate for differences in the completeness of reporting, the attack rate at each age was expressed as a ratio of the attack rate at all ages. The specific age ratios for Baltimore, representing an urban community, were compared with those for the rest of Maryland, predominantly rural. It was found that

children in the city are still (1935-1940) attacked at an earlier age than are those living in the rural part of Maryland, but the age of attack among children living in the rural areas today is almost the same as that of the children who lived in the city before the last war (1917-1918).

These data are limited, but they lend support to the conception (1) that the changes in living conditions of the past quarter-century have tended to accelerate and broaden the antigenic experience of the younger generation, and (2) that a greater proportion of the young adults who enter camp and industrial areas are immune to common infections. On the other hand, it is difficult to reconcile this concept of earlier and more intensive natural immunization with the observed fact that the trend in the death rate among children from infectious diseases has been progressively downward during recent years.

During this same period an increasing proportion of the public have acquired better habits of personal hygiene. Promiscuous spitting, sneezing, and coughing in public places have been reduced. The use of paper drinking cups has become popular. Greater cleanliness in the methods of handling and serving foods is demanded. Housing and ventilation have been improved. These and other changes in the hygiene of living have had a definite, though immeasurable, effect in reducing the volume and rate of exchange of respiratory pathogens. Finally, and perhaps most important of all, it must be borne in mind that lowered infectivity and pathogenicity of the prevailing strains may be the important factor. If so, the introduction of new strains may take place at any time and lead to increased morbidity and mortality from respiratory infections.

Since the relative importance of these and other unknown factors can-

not be evaluated, only time will tell. The balance between the human host and certain of these parasites may already have been disturbed to an extent that a downward or stationary trend has been converted into a rise. Not yet apparent in the form of epidemics, it will be reflected first in the rates of endemic incidence.

Within the last two years there has been a definite increase in the incidence of cerebrospinal meningitis—a disease which is a sensitive indicator of the effect of population shifts and crowding. In England and Wales the reported cases were as follows: 1938, 1,288 cases; 1939, 1,500 cases; 1940, 12,500 cases.⁶ In spite of a lowered case fatality rate due to chemotherapy, the deaths from cerebrospinal fever in the first two years of the war, up to the third quarter of 1941, were about four times as numerous on the average of the years as in 1938–1939.⁷ In the United States this disease has shown a definite increase since the first of this year. Up to the week ended June 27, the total number of cases reported to the Surgeon General of the U. S. Public Health Service was greater than for a similar period in any year since 1937. Significantly, the increase appeared in the Eastern Seaboard states—Massachusetts, New York, Pennsylvania, New Jersey, Maryland, the District of Columbia and Virginia—and in California, the industrial areas into which people have been crowding.

In this discussion an age-old enemy of mankind, and a reliable index of physiological, social, and economic well-being, must not be forgotten. In England and Wales deaths from respiratory tuberculosis increased by 6 per cent in the first year, and by 10 per cent in the second year of the war.⁷ In the United States,⁸ judging by the experience of the Industrial Department of the Metropolitan Life Insurance Company, the death rate from

tuberculosis of the respiratory system has maintained its downward trend among industrial policy holders through the first five months of 1942. Sufficient time has hardly elapsed, however, to expect to find a definite indication of a change in the trend in death rates from a disease of long duration.

The epidemiological implications of population shifts with regard to exotic tropical diseases is more difficult to assay. Their importance to the armed forces in Africa, the West Indies, Central America, and the Far East is real and immediate. The threat to the civilian population of the United States still seems remote, with one possible exception, and that is yellow fever. The spread and volume of air travel under the exigencies of military and naval operations has rendered ineffective such measures of quarantine as were formerly in force. That there are sufficient numbers of *Aedes aegypti* in certain towns and cities of the southern United States to support an epidemic is indicated by the outbreaks of dengue which have occurred within recent years. The only remaining defense against importation is specific immunization of exposed persons.

SUMMARY

Although the continental United States has not yet been engulfed in devastating warfare, industrial and military mobilization has brought about extensive population movements which are continuing. The shifting has been principally an evacuation from the rural districts to urban reception areas. In many of the cities and towns adjacent to military and industrial establishments conditions have been created which are potentially dangerous from an epidemiological viewpoint. Yet the experience thus far from infectious diseases has not been unusual. The period of elapsed time has been

relatively short. The trend of certain infections which are indices of social welfare should be followed with careful attention. The potential hazards in the immediate future would seem to be principally from viruses and bacteria with which we are already familiar, especially those which are parasites of the human respiratory tract.

Protection of Water and Food Supplies in an Emergency*

G. E. ARNOLD

Sanitary Engineer (R), U. S. Public Health Service, Ninth Civilian Defense Region, San Francisco, Calif.

WAR causes many changes in the normal way of life. Some of the expected changes are population shifts, new production methods, shortages of important materials, substitutions, lower standards of manufacture and inspection, and the appearance of new products and new methods.

An emergency may be created in any one of a number of ways, other than by war—from fire, flood, hurricane, earthquake. For the purpose of this paper the emergency resulting from war or enemy action is used as an example, but many of the matters discussed could originate in any one of a number of ways.

Food is obviously essential for maintenance of civilian health and morale, as well as for military personnel and defense production.

Water is the life blood of any community. Its use for washing, sanitation, drinking, food preparation, and to fight fire, is so completely taken for granted that it is seldom thought of until the supply is interrupted or cut off entirely.

WATER SUPPLIES

The following are a few things that may happen to a water system in an emergency:

The system may be seriously over-

loaded by increased population and war production. Drought or enemy action may result in depletion of the supply. Lack of material may result in the substitution of inferior materials for construction and repair. The water system may be affected through enemy action by bombing, shelling, sabotage, gas attack, power failure, poisoning, or bacterial pollution. All of these things can be fairly and adequately met by proper precautions.

America has the highest standards of water supply in the world. These standards must be maintained. The water supply should be protected at its source against the possibility of pollution or enemy action. The water treatment plants should be protected. The transmission and distribution systems should be surveyed for defects, and protective measures should be taken.

In protecting a water system against accidents, or against trespass which may result in sabotage, a number of points should be mentioned. Visitors should be excluded from operating properties of the water system. These properties should be fenced and posted with conspicuous signs warning against trespassing. Guarding is frequently over-emphasized. Guarding of property by a man is the most expensive form of protection, and results are not always satisfactory. Guards, where used, should not be posted in conspicuous or isolated places without some protection

* Read before the Western Branch American Public Health Association at the Thirteenth Annual Meeting in Seattle, Wash., May 27, 1942.

to themselves, such as fencing or alarm devices. Guarding should be correlated with a communications system, the guards being required to report in at frequent, regular intervals. Should any guard fail to report on schedule, the reason should be investigated.

Many people are concerned about the possibility of poisoned water supplies. The mechanics involved in poisoning a public water supply are such as to minimize the likelihood of this type of sabotage. Large quantities of poisonous compounds are necessary to poison a water supply effectively. These compounds are frequently expensive and not readily obtainable. Most poisons tend to hydrolize rapidly in water and are not effective unless thoroughly mixed with the water.

Certain simple tests can be readily made by any laboratory or water works man for the detection of unusual conditions indicating pollution or poison in the water supply. A sudden change in pH is an indication of some unusual condition in the water. A sudden decrease in the dissolved oxygen content, or an increase in the oxygen consumed value indicates the presence of an organic substance which may have been added to the water. A sudden increase in chlorine demand or a disappearance of the chlorine residual indicates the presence of an unusual substance. The sudden appearance of a taste, odor, or color in water should be investigated. These tests are simple, easy to make, and are a good indication of any unusual condition in the water supply.

Bacterial pollution of water supply is also a possibility, but again the mechanics involved in obtaining and introducing disease organisms reduce this possibility. A chlorine residual throughout the distribution system provides one safeguard against this type of contamination. Frequent bacteriological examinations of the water supply should be made.

Usual methods of water treatment, consisting of coagulation, filtration, and chlorination provide reasonable safeguards against bacterial and chemical pollution.

Bombing and shelling introduce complicating factors. Bombs may break parallel water and sewer pipes and the bomb crater may fill up with a mixture of water and sewage. The sewage is likely to drain off into the water system. The occurrence of fire, which nearly always accompanies bombing or shelling, results in great increases in water consumption with attendant low pressures.

To meet this emergency situation there is being developed throughout the country a mutual aid plan involving the exchange of materials, supplies, equipment, and personnel. An inventory of these materials is being made and an organized plan of exchange among water systems is being worked out under the direction of water supply coördinators who are part of the Civilian Defense organization.

The mutual aid plan also seeks to provide auxiliary water supplies for use in event of failure of the regular supply connections between water systems of adjacent communities, emergency chlorination and treatment of auxiliary supplies, provision of auxiliary power sources in the event of power failure, and protection of the sources against subversive action. This plan has been thoroughly organized in most localities, and is ready to function in an emergency. Any community not having such an organization should start one.

FOOD SUPPLIES

Any one of the following things may affect the food supply of a community: bombing, shelling, gas attacks, sabotage, lower standards of raw foods, lower standards of food preparation, lack of inspection, and the use of substitute foods.

In an emergency, supplies should still be protected from the source to the ultimate consumer. Lack of personnel already threatens a lowering of inspection standards. It is imperative that inspection be carried on at the usual level.

Unusual circumstances, such as blackouts, increase the problems of preparing and handling foods. Changes in the use of containers and of material in containers have introduced new problems. The use of new types of containers requires careful supervision to insure proper sanitation. The possibility of polluted water supplies used in food manufacture should be watched and guarded against.

STORAGE OF FOODS

With increased complications in transportation, and the possibility that portions of the country may be isolated by enemy operations, there is a likelihood that storage of foods will become necessary in some locations.

In England special buildings have been constructed for the storage of food. The buildings measure approximately 120 x 220 feet and hold 8,000 tons of food. They are built of reinforced concrete, and all openings can be tightly sealed against gas attacks. The construction of such buildings is probably not necessary in this country, but provision should be made for the storage of foods in existing structures. Where possible, food should be stored in or near a hospital or institution where large quantities of food are regularly used. The institution can use up the older stock first, to maintain a regular turnover and reduce the likelihood of spoiling. Regular inspection should be made of all stored foods to see that they are in good condition. Precautions should be taken to protect foods against insects and vermin.

BOMBING AND SHELLING

A bomb burst will shatter glass panes

for a considerable distance from the blast itself. Shattered glass, flying in all directions, may readily destroy food. The explosion also raises dust, which settles on exposed food. By way of precaution the quantity of food on display should be reduced to an absolute minimum, especially that displayed under glass. Slivers of glass driven into meat may not be detected until the meat is consumed.

In some cases it may be desirable to protect certain storage plants by sandbagging or protective walls. Due to the shortage of bags and their tendency to deteriorate, sandbags are not favored. A simple protective wall may be formed by constructing wooden forms, as is done for a concrete wall, and filling them with an earth-asphalt mixture.

Refrigeration machinery, which is expensive and difficult to replace, should be protected against damage. The escape of refrigerant gases in case of a bomb hit or near-miss may complicate the situation. Storage plants should be effectively blacked out so that they can operate continuously. Ventilation is difficult during blackouts except by forced draft. Provisions should be made to clear refrigeration gases from plants as quickly as possible after bombings; some gases, particularly ammonia, are toxic in low concentrations.

GAS DAMAGE

Gases used in enemy action are of two types, persistent and non-persistent. The persistent gases such as mustard and lewisite come in an oily form which slowly vaporizes. The non-persistent gases are mostly irritants and smoke; they are readily dispersed by the wind. Following a persistent gas attack any contaminated material should be treated to neutralize the effect of the gas.

PROTECTION OF FOODS AGAINST GAS

The greatest danger to foods comes from the oily vesicant gases.

1. *Protective Measures*

a. Wherever possible vulnerable foods, e.g., those stored in sacks, hessian wrappings, open crates, etc., should be stored elsewhere than on top floors or in basements.

b. Tarpaulins, preferably of the impervious, oil-painted variety, or oilskins are the best kind of cover for storage of foodstuffs in packages. They give good protection against oily splashes of liquids such as mustard gas. Such protection greatly reduces the labor of the decontamination personnel.

c. Wherever practicable the tarpaulin should closely cover the pile of packages, but when this is not convenient it can be arranged as a covering fastened on hooks or frames so as to form a screen or curtain. Where free circulation of air is essential for satisfactory storage, as for fresh fruit in crates, etc., the screens or curtains should be arranged so that they can be pulled into position as soon as a raid warning is given.

d. Canvas or sacking can be used for coverings or screens when tarpaulins or oilskins are not available. They give no protection against gas or vapors, but soak up the oily drops of liquids, thereby reducing contamination. Anything that helps to protect the food containers from being splashed is of value.

e. Food in chambers, such as refrigerator stores, cold rooms, gas chambers, etc., requires no additional protection from gas, providing the doors are reasonably gas-tight and precautions have been taken against contaminated air entering by a ventilation system.

2. *Decontamination*

a. Bulk supplies of food which have become contaminated by poison gas should not be touched except by those fully trained in decontamination methods and adequately equipped with protective clothing, respirators, etc. Rough-and-ready attempts to decon-

taminate may lead to injury of persons and to loss of food which otherwise might have been salvaged. If trained personnel is not immediately available, a report should be made without delay to a gas officer or to the health department.

3. *General Precautions against Gas*

a. Refrigerators and cold storage lockers give good protection against gas if they are reasonably airtight. Doors and fittings should be examined to see that they are in good condition.

b. The exposure of food in windows or on open shelves, where liability to contamination is greatest, should be reduced to a minimum.

4. *Precautions to Be Taken in the Event of an Air Raid Warning*

a. All windows, doors, shutters, etc., should be closed, and any other precautions taken which time permits, to shut off the food supplies from contact with the outside air.

b. Extractor fans or other artificial ventilating systems that draw outside air into the food store or chamber should be shut off.

5. *Protection of Foodstuffs in the Home*

a. Store as much food as possible in cans with tight-fitting lids or in bottles with good stoppers or screw-caps. Clean, dry biscuit cans serve to hold supplies of flour, rice, pea-flour, and similar non-perishable foods. If they are reserve supplies the cans or bottles can be carefully wrapped before being put in a cupboard or on a shelf.

b. Perishable foods, such as meat, fish, eggs, milk, butter, etc., are quite safe if kept in one of the ordinary types of domestic refrigerator, providing the door forms a reasonably airtight seal. In other cases, protection for perishable foods should be contrived by the intelligent use of cans, bottles, or wrappings of the type mentioned above.

6. *Food and Livestock in Markets*

a. All contaminated food should be held until it has been inspected by the local public health officials, who will decide whether it can be decontaminated or whether it must be destroyed.

TABLE 1

MATERIALS USED FOR COVERING OR HOLDING FOODSTUFFS

<i>Nature of Covering</i>	<i>Protection against Poison Gas or Vapor</i>	<i>Protection against Liquid Poison Gas</i>
Sealed metal drums	Complete	Complete
Sealed metal-lined cases or casks	Complete	Complete
Sealed cans	Complete	Complete
Cans with well fitting lids but not sealed	Fairly good	Good
Glass bottles, glazed earthenware vessels, with well fitting stoppers or lids of glass, metal, bakelite, or similar impervious materials	Complete	Complete
Bottles or glazed vessels with ordinary cork stoppers	Fairly good	Good
Sealed wooden barrels such as are used for transporting and holding liquids	Complete	Complete, except in cases of heavy and prolonged contamination which may impregnate the wood to a significant depth
Bottles and jars covered by grease-proof paper	Fairly good	Moderate, but additional protection can be provided by an outside covering of a transparent cellulose wrapping*
Waxed cartons	Good if well sealed	Good if all joints are waxed or covered by a layer of a transparent cellulose wrapping
Papier mache cartons	Good if well sealed	Fairly good. A transparent cellulose wrapping gives additional protection
Transparent cellulose wrappings	Good	Good
Metal foil wrappings	Good if no pinholes	Good if no pinholes
Oilskins, tarpaulins	Fairly good	Good
Bags lined with transparent cellulose wrapping	Good	Good
Grease-proof paper	Good	Fairly good if contamination slight
2- or 3-ply bitumen or tar-lined paper	Good	Fairly good if contamination slight
Wooden boxes	Good if all joints tight	Poor. Soft woods are very absorbent
Thick cardboard boxes	Good if all joints tight	Poor, very absorbent
Paper containers	Poor	None
Sacks, canvas, hessian, and other textiles	None	None (except when used as screens)

* Many types of cellulose wrappings are on the market. Those prepared from cellulose, cellulose acetate and nitrocellulose are, in general, good as protective wrappings against gas. Those based on benzyl cellulose are less satisfactory.

PROTECTIVE CONTAINERS

Protection of foods against gas can be adequately accomplished by the use of a proper container. Some containers are quite effective, others are almost entirely ineffective.

Protective Value of Materials Used for Holding or Covering Foodstuffs

The relative protective value of a number of materials commonly employed for packing foodstuffs is shown in a list (see Table 1).

THE EFFECT OF GAS ON FOODS

Gas has a very definite effect on most foods. Some foods can be salvaged following gas attacks, others must be destroyed. The following table is presented giving some foods indicating the effects of phosgene gas. The same effects may be considered with other gases except that the arsenic gases are definitely dangerous. Mustard is more

persistent and more difficult to treat than phosgene.

MILK

Milk, an essential food in any community, should be protected against damage. Bombing may destroy milk plants. Substitute plants should be available, or some other means of handling the milk supply should be provided. The milk industry might well consider the possibility of a mutual aid plan for the handling of milk.

Pasteurization is essential to the protection of milk supplies, and provisions should be made for emergency pasteurizing plants. Cheese, ice cream, and butter plants, with some adjustment, may be utilized for this purpose. Vehicles for the delivery of milk and dairy products should be decentralized, so that one bomb cannot disrupt the delivery service.

The possibility of sabotage through

TABLE 2

EFFECT OF PHOSGENE ON SOME FOODS

<i>Food</i>	<i>Effect</i>	<i>Whether Dangerous</i>	<i>Treatment</i>
Flour	Becomes sour and slightly unpalatable. May make a poor loaf	No	48 hours' airing. Can then be blended with 5 parts of undamaged flour and will bake normally
Bread	Outer layers may become unpalatable	No	Cut away outer layers and air remainder
Cereals	Negligible	No	48 hours' airing
Meat and Fish	May become slightly discolored on the surface	No	Condition improved by airing and cooking
Milk	May slightly affect taste	No	Bring to boil
Eggs	None	No	...
Cheese, Butter, Margarine, and Fats	May bleach slightly on surface	No	If bleached, cut away affected part, which may be used for cooking. Remainder is edible
Dried Fruits	Slight loss of palatability	No	Air and cook
Fresh Fruits	Almost none	No	Air and peel off skin or outer layer
Fresh Vegetables	Green vegetables may be slightly bleached	No	Air and cook
Tea, Coffee	May become bitter and unpalatable	No	None is effective, but such material might be used for blending

the milk supply should not be overlooked. Milk is subject to pollution from its source to the consumer. Pasteurization protects against all forms of vegetative bacteria, the group that includes most of the disease producing organisms. Adulteration and contamination of the milk supply following pasteurization should be guarded against.

Milk truck drivers, employees of milk plants, and even delivery men, should be thoroughly investigated as to loyalty. Riders or hitch-hikers should not be permitted on milk trucks. Covers on milk tanks and trucks should be sealed and rigidly inspected. Milk absorbs some gases, and an exposed milk supply will probably have to be destroyed after a gas attack. Bottles or paper containers for milk are effective protection as long as they are tightly sealed.

The use of paper containers for fresh milk has the advantage of conserving space and weight. Twelve quarts of milk in glass bottles weigh approximately 60 pounds. The same milk in paper containers weighs only 25 pounds and occupies about half of the space required for glass containers. This is an important factor in the rubber tire shortage and the consequent food delivery problem.

The War Production Board has restricted the use of tin to about 50 per cent of its normal consumption. The canning industry will reduce the probable consumption of tin by about 50 per cent. There were on hand in this country, at the end of 1941, about 140,000 tons of tin. Our importations from South America are normally about 18,000 tons a year, plus 11,000 tons from Africa, and it is expected that the tin salvage campaign will result in the production of about 6,000 tons a year. The normal consumption of tin is about 70,000 tons a year (although we consumed more than 110,000 tons in 1941), but by economical use and new methods

this may be reduced to 50,000 tons or less a year. The electroplating process, to take the place of the dipping process eventually will reduce tin consumption in the tin plate industry to about one-third of the former rate. Electroplated cans are good for approximately two years with most products, except in extremely warm climates. Any product with a pH above 5.0 needs no tin.

The use of glass containers is being expanded as far as possible, but they are not suitable in all cases because of the expense involved, the use of critical materials, and the shortage of rubber for jar rings, though plastic rings are coming into use to a certain extent. The dehydration of foods is being largely expanded. The principal drawback is the product's lack of appeal. An educational campaign is needed before consumers will be willing to buy products differing so much in appearance from the fresh or canned foods to which they are accustomed.

The use of containers for military purposes is greatly increasing. Practically all foods shipped to the armed forces must be protected with metallic containers because of rough handling, extremes of temperature, vermin and weevils. Sugar and flour, normally placed in bags, have to be encased in metal containers for use in the tropics.

The use of large containers for products which have to be sterilized in the container is extremely difficult because of the length of time required for proper heating. It is possible to bring a normal can to a uniform temperature of 240° F. in a few minutes. The same product in a large container holding as much as 10 gallons would require 16 hours of heating.

The milk industry uses an enormous number of cans for the condensed and evaporated product. There is an increasing tendency toward the substitution of dried milk, which may be packed in metallic or non-metallic containers.

There may be consumer resistance to dehydrated milk as to other dried foods. The protective problem is the same as for other packaged foods.

CONCLUSION

Public health people are facing many problems resulting from the war. The war is only one of the emergencies with which we may be faced, but it is probably the most extensive, affects the most people, and is the most prolonged of any emergency we can anticipate.

The shortage of certain materials and of personnel has resulted in extensive substitution of foods, containers, and

processing methods. Inspection is difficult because of limited personnel.

The water and food industries are facing unprecedented emergencies, and public health people should be prepared to meet these emergencies when they arise.

Let's not be caught with our water plants down, and let's keep 'em eating.

The Massachusetts Vision Test

An Improved Method for School Vision Testing *

LURA OAK, PH.D.

Head of Field Service in Child Growth and Development, Division of Child Hygiene, Massachusetts Department of Public Health, Boston, Mass.

THE new vision test recently introduced into the schools of Massachusetts represents an effort to bring screening procedures used in schools more nearly up-to-date and in line with practices approved by leading eye specialists. It was constructed through the coöperative effort of eye specialists and educators working in the schools.

According to descriptions of vision testing programs received from 43 other states,† Massachusetts ranks high among the states recommending comprehensive vision service in the schools. A summary of conditions here, therefore, may not be far amiss in pointing out inadequacies existing generally throughout the country.

The law of Massachusetts covering the vision testing reads as follows:

CHAP. 71, SEC. 57. Testing for Defects—Physical Record. The committee shall cause every child in the public schools to be separately and carefully tested and examined at least once in every school year to ascertain defects in sight or hearing, and other physical defects tending to prevent his receiving the full benefit of his school work, or requiring a

modification of the same in order to prevent injury to the child or to secure the best educational results, and shall require a physical record of each child to be kept in such form as the department may prescribe. The tests of sight and hearing shall be made by the teachers, directions for which shall be prescribed by the Department of Public Health.

CHAP. 71, SEC. 58 (As amended by Chap. 287, Acts of 1935). Furnishing of Test Cards, Blanks, etc. The department (of education), after consultation with the department of public health, shall prescribe and furnish to school committees suitable rules of instruction, test cards, blanks, record books, and other useful appliances for accomplishing the purposes of sections fifty-three to fifty-seven, inclusive, and may furnish said material to such boards of health, as may require it in the performance of their duties. The department may annually expend therefor a sum not exceeding twelve hundred dollars, and shall provide for pupils in the teachers' colleges instruction and practice in the best methods of testing the sight and hearing of children.

The Department of Education, accordingly, has supplied each teacher with a test card and instructions for giving the Snellen test for visual acuity. The record for each child is transferred to his general health record during the first month of each school term and then filed with the superintendent or the school nurse. It becomes the duty of the latter to retest all children who fail the test as given by the classroom teacher. Such failure, if corroborated by the nurse's retest, results in notification to the parents and the suggestion that the child be taken to the family eye specialist. The plan was well con-

* The material of this paper is based upon a study conducted by a staff composed of the following members of the Massachusetts Department of Public Health: M. Luise Diez, M.D.,† Division of Child Hygiene; Albert E. Sloane, M.D., Consultant Ophthalmologist; Lura Oak, Ph.D.; John W. M. Rothney, Ed.D.; Miriam Forster, M.A., and Philip W. Johnston, Ph.D. The work was made possible by a federal grant to the Division of Child Hygiene.

† Deceased.

‡ Received in reply to a questionnaire sent out to all state departments of health. Eleven questions were submitted which were designed to cover contemporary school vision screening practices.

ceived and, on the surface, may appear to take care of the matter. Actually, the practical working out of these provisions has fallen far short of meeting the needs of the children.

The breakdown in the Massachusetts plan appears at four points: (1) failure of those giving the test to conduct it properly; (2) lack of resources for providing follow-up examinations and treatment, especially in underprivileged communities; (3) the inadequacy of the Snellen test, alone, as a test of visual function; (4) the fact that direct or indirect financial interests of some eye specialists interfere with honest professional service to the children.

During the course of our 3 year study of school vision testing it was possible to observe at first-hand the operation of the program in this state, and also to carry out certain minor investigations subsidiary to the main survey* being made. Those directing the study within the schools included an ophthalmologist and two educational psychologists.

By visiting classrooms while the regular vision test was being conducted, it could be observed that memorizing of the chart by the children was a common practice which some teachers failed to observe. Children were seen to take the test as though reciting a section of the alphabet and probably without any idea that they were cheating the record. Among the younger children the idea uppermost appeared to be to simulate the illiterate symbol (E) with hand movements. They were intrigued with hand-turning rather than with revealing what they could see on the chart at 20 feet. Often these youngest children were observed to practise near the chart. Upon the subsequent test by the teacher they were merely recording a practised hand exercise which might be executed

without the necessity of seeing all of the symbols. A 15 year old boy who had become sightless in one eye, yet had had a passing record for that eye on his health card each year, proved to us that he could still say the test "by heart" as he had learned it at 6.

The responsibility for such mistakes rests with the individual teacher or nurse giving the test, though it should be noted that the small chart in use here for several years, with a maximum of six test units for each rating, would probably become familiar to any intelligent child after a few repetitions. Skipping and reversing the sequence, however, probably lowers the chances of memorizing. Obscuring the card from all except the one being tested also reduces the chances of error in the record. These precautions were observed by some of the teachers.

Another unfavorable feature noted in many classrooms was unsatisfactory lighting. A 20 foot distance was usually marked off with a view to space and convenience and all testing was subsequently done at this spot. Lighting, glare, or shadows received only secondary attention, regardless of how these varied with weather and time of day.

In studying the validity of the tests as they are generally given, a random selection of 368 Snellen test records made by 50 teachers was compared to the Snellen test records for the same children (ages 8-13) made by our staff ophthalmologist.† The two sets of records for visual acuity were found to correspond in 237 cases (64 per cent) and to disagree in 131 cases (36 per cent). In this and other comparisons made during the course of the study the discrepancy between such records indicated that the tendency of error was

* This was an investigation into the causes of early school failure through a study of handicapped children in selected areas of the state.

† The comparison of such records in so far as they indicate that the teachers' findings are inferior is based upon an assumption of perfection in the experts' record, a result which may be only approximate for any given examiner.

toward a lower rating (indicating lowered vision) in about two-thirds of the cases and toward a higher rating in one-third of the cases in which a disparity between records occurred. The practical interpretation of these findings suggests that, while some children are sent needlessly to the family eye specialist, a number with lowered visual acuity are being overlooked.

By means of a similar comparison between the Snellen records of a single teacher with special aptitude and skill in giving the tests and records of the staff ophthalmologist for the same children, the importance of individual differences among teachers is suggested. For example, in the case of one of the more capable teachers who had given the Snellen tests to all children (294) throughout a school, there was agreement with the specialist's findings in 230 cases (78 per cent) and disagreement in 64 (22 per cent).

Conclusions to be drawn from our observation of school testing by the teachers and a study of records may be summarized as follows:

1. The Snellen test as used by teachers at present is but a coarse screen for sorting out some of the children who need an eye specialist's attention.

2. The validity of the test may be increased through the selection and training of qualified persons.

3. The reliability of records could be increased by improvements in materials and methods with a view to minimizing opportunities for memorization.

4. Calibrated standard illumination upon the charts should also result in more accurate records.

The school nurse in Massachusetts holds an important place in the vision testing program. Frequently, the superintendent gives her complete responsibility for supervising the initial testing by the teachers, for giving retests to those who fail, and for checking the notices to parents in cases where the attention of the family specialist is

indicated. Many superintendents and some nurses have expressed the belief that vision testing is the province of the health division, including the school nurse. Where such conclusions had been made it was usually observed that the personality of the nurse, her effectiveness in parental contacts, and the limits of her pupil load were so combined that she could undertake the vision work without jeopardizing other duties. The practice most commonly observed throughout the state was the routine testing of all children by each teacher and the retesting by the school nurse of all who had failed.

Among school nurses, as among teachers, a wide range of individual differences appears in the administration of duties in the vision program. The extremes show, on the one hand, instances where only casual effort is made and, on the other hand, the work of the highly efficient nurse who sees to it that each referred child is carefully retested and, when the records indicate, receives the needed ocular attention.

Our close contact in the schools during the 3 year period led us to note certain shortcomings in service rendered by some school nurses. The following summary presents a composite of factors which need correction here and there, rather than a fair commentary upon practices in general.

1. Nurses do not always distinguish between the results of a screening test and a professional diagnosis. Parents, therefore, have been confused and often needlessly annoyed. Notices to parents regarding failure on a vision test should be free of suggestion that the child needs glasses. Diagnosis should always be left to the specialist. The implication of the notice to parents, whether written or verbal, should be: In our school vision test your child did not make a perfect score. In order to make sure that his vision is normal or that any deficiency may be corrected, will

you please have his eyes checked by your family specialist.

2. Nurses, themselves, are frequently uninformed regarding the nature of a specialist's service. The wearing of glasses does not necessarily mean that the child's problem is finally solved. In many cases a child wearing glasses should return frequently to the specialist to be rechecked. The appearance of symptoms in a child, even if his glasses are new, should be an indication to refer him again to the specialist unless it is known that the latter is aware of the symptoms and disregards them in that case.

3. While nurses may not recommend specialists to the parents, they may suggest that the family physician be consulted for the name of a qualified eye specialist. Lacking such guidance, numbers of parents take their children to department store counters where glasses are bought as hair ribbons or tooth brushes are bought. Others are supplied from discards found around home. Frequently the spectacle merchant with the biggest sign or window display attracts the majority of those who are seeking professional services without understanding or guidance.

4. Nurses should inform themselves regarding the professional services available to their communities and assist in efforts to encourage high standards. The earmarks of good service for children are to be found, not in the kind of letters at the end of the specialist's name, nor in office equipment, window or sign displays. They can be judged to some extent by a knowledge of the length and thoroughness of his special professional training, the sincerity and honesty of the specialist as known to those who have availed themselves of his service, and also the particular interest and skill revealed by him in understanding and handling children. Nowhere is the personal equation of greater significance. The younger the

child, the greater is the importance of a patient, sympathetic manner on the part of the examiner.

Until such a time and means can be found for a complete ocular examination by a qualified specialist for each child, the measures to be taken by the school will fall short of satisfactory solution. Non-specialists, such as nurses and teachers, should not be expected to make a diagnosis. No instrument or set of tests based upon the child's subjective reactions should be counted upon to yield perfect results. At best, the school test should detect all who need ocular attention, including the "borderline" cases.

In this connection, it should be mentioned that wide differences exist in the practices of individual specialists and that variance in standards for prescribing glasses reflects upon the efficiency of the school test in any given community. For example, if the school test should be designed to sort out children with a refractive error of, say, one and a half diopters of hypermetropia (far-sightedness) and such children are referred to a specialist opposed to fitting children of young age for this degree of simple hypermetropia, the school test may come into disrepute among the specialists and the parents of children so referred. If, on the other hand, the same test is used in a community where the specialists are inclined to prescribe glasses to certain children for this degree of refractive error, the test is credited with higher accuracy. Some specialists prescribe treatment for all so-called borderline cases, while others decline to fit any of them. The relative accuracy and the popularity of a school vision test are found to rest to a considerable extent upon the professional philosophy of local specialists.

The watchword for those seeking to improve the school's effectiveness in keeping check on children's eyesight may well be phrased in the familiar

words of Sidney Webb: the *inevitability* of *gradualness*. Education of the public, insistence upon standards of service, and conscientiousness in the use of improved materials to the end that greater improvements will result—these are the objectives of public health minded individuals everywhere.

The new Massachusetts Vision Test* now available for general use is designed to meet the need for improved procedures which will bridge the gap between present inadequate provisions and the time somewhere in the future when the eyes of all children will be examined by a qualified eye specialist. It was developed after a 2 year study in which over 6,000 children were tested and checked against an ophthalmologist's examination.

The administration of the test requires an average time of $2\frac{1}{2}$ minutes for children 8 years of age or older. Slightly longer time is allowed for those who are younger. The same test (with only a change in one item) can be used for all children from 5 to 18 years of age. Anyone accustomed to working with children can successfully administer the test by reading the instructions and practising the routine four or five times.

The test kit can be purchased in carriers if the portable feature is desired.

It consists of the standard Luckiesh Moss Illuminator*; the improved form of the Snellen Test card; a house chart mounted on a frame with an electrical unit and light source; a near phoria tester, also with an electrical unit and light source; spectacles with plus sphere lenses, others with Maddox rods; and a central switch for controlling the lights.

In addition to the usual test for visual acuity, the series also provides tests for latent hypermetropia and for muscle imbalance.

After 2 years of use in many school systems throughout the state, the consensus of opinion among eye specialists and school departments is generally very favorable toward the test as a whole. The additional features are usually recognized as significant improvements. In a few situations, however, where the local eye specialists are skeptical about testing for any condition except visual acuity, there is considerable lag between the numbers screened (roughly 35 per cent) and those receiving correction (20 per cent).

If the form of the new test results in lively controversy over the innovations this is to be welcomed, since the result is heightened interest in problems of school vision testing and a broader education for all who are concerned in its solution.

Field Equipment for Food Inspectors

FERDINAND A. KORFF, F.A.P.H.A., AND
EMANUEL KAPLAN, Sc.D.

Director, Bureau of Food Control, and Chief, Division of Chemistry, Bureau of Laboratories, Baltimore City Health Department, Baltimore, Md.

THE scope of activities of the food inspection staff of the Baltimore City Health Department has been greatly extended during recent years. This was done largely by providing the inspectors with improved testing outfits. The new outfits make it possible to sample materials more efficiently and permit a variety of chemical testing during the course of inspection. In this way a considerable reduction is effected in the number of samples which otherwise would have been submitted to the Bureau of Laboratories of the department. Moreover, the removal of hazardous chemicals and spoiled food from food establishments is greatly expedited. It is the purpose of this paper to describe the methods and equipment used by food inspectors of the Baltimore City Health Department for making some analytical examinations in the field.

FIELD EQUIPMENT

Each inspector has a convenient leather case (Figures 1 and 2) which contains the usual detention cards, violation notices, copies of laws, educational forms and leaflets, sample identification cards, and such conventional equipment as flashlight, thermometer, can opener and meat trier. Paper bags and paper spoons are carried for collecting food samples; sterile 4 oz. bottles for water samples, and sampling vials for food utensil swabbing. Portable apparatus is also provided for the detec-

tion of fluorides, cyanides, cadmium, arsenic, and sulfites; equipment is included for testing the strength of chlorine solutions used as disinfectants and for the detection of spoilage of shucked oysters and crab meat. Wherever possible, testing materials are contained in uniform glass vials and each case is fitted with a wooden rack to hold the apparatus. All solutions, test papers, and other equipment are periodically replaced and reconditioned by the Bureau of Laboratories.

ANALYTICAL PROCEDURES

1. *The Detection of Spoilage of Shucked Oysters—*

The usefulness of pH measurements of oyster liquor as an adjunct to organoleptic examination in the detection of spoilage of shucked oysters has been demonstrated by several investigators.^{1,2} The pH of fresh shucked oysters varies between 6.0 and 7.0. A pH value of 5.4 to 5.8 is regarded with suspicion, while values below this range are indicative of decomposition. A convenient field examination is made by transferring 5 ml. of oyster liquor to a test tube graduated at 5 ml. and adding 0.5 ml. of methyl red indicator solution (0.02 per cent methyl red in 50 per cent alcohol). After mixing, the color produced is compared with the methyl red color standards in sealed glass ampules. Standards reading pH 5.4 and 6.0 are provided. If there are indications that

FIGURE 1—Leather case containing equipment

the oysters have been recently washed, several drops of the indicator solution are placed directly on the oyster. The production of a persistent red color indicates spoilage.

2. *The Detection of Spoilage of Crab Meat—*

The decomposition of crab meat involves a progressive proteolysis, accompanied by a rapid rise in the ammonia

FIGURE 2

Food Inspector's Field Equipment

content of the meat. In 1932 Harris³ proposed the Nessler ammonia test as a means of differentiating fresh from spoiled crab meat. The test used by our inspectors is done in this manner: About 1 gm. of crab meat is transferred to a test tube and shaken with several ml. of water, and 2 to 3 drops of Nessler's reagent are then added. The immediate development of a deep yellow or brown color indicates spoilage of the meat. The test is used only as an aid to organoleptic examination of the suspected crab meat.

3. *The Detection of Cyanide in Metal Polish—*

In 1930, Williams⁴ pointed out the possible rôle of metal polish which contained cyanide in cases of gastroenteritis. In 1938 the Maryland State Department of Health adopted regulations governing the retail sale or use of cyanide containing preparations. Many other communities have similar legislation.⁴

The qualitative detection of cyanide in metal polishes in the field may be conveniently made with sodium picrate test papers.⁵ This test paper is moistened with water and is then suspended in the container of the suspected polish. Care is taken that the paper does not come in contact with the material. The paper turns orange and then brick red in 5 to 10 minutes if the concentration of cyanide (as KCN) exceeds 0.5 per cent. Although the reaction is not wholly specific for cyanide, the method serves as a ready screening test in the field.

4. *Cadmium—*

Because of the difficulty in obtaining aluminum and stainless steel there has been a tendency on the part of the equipment manufacturing companies to use cadmium for plating utensils and equipment. A number of food poisoning outbreaks attributed to the consump-

tion of acid foods stored in cadmium-plated vessels have been reported.⁶ Warnings of the dangers of the use of cadmium-lined utensils have been issued to the newspapers by the Federal Security Agency.

A simple testing unit to detect cadmium during the inspection of food establishments in Baltimore was devised.⁷ The outfit consists of two small vials. One contains strips of filter paper which have been impregnated with a 20 per cent sodium sulfide solution and dried; the other contains small cotton swabs immersed in 10 per cent nitric acid. The swab is rubbed on the suspected metal and is then applied to the sodium sulfide paper which has been previously moistened with water. The instantaneous appearance of a canary yellow stain on the paper indicates the presence of cadmium.

5. *Available Chlorine in Disinfectant Solutions—*

Regulations of the Maryland State Board of Health require that all food containers (drinking glasses, plates, forks, etc.) used in establishments dispensing food or drink, after cleaning and rinsing, must be disinfected either by immersing in water at 180° F. or above, or by immersion in a solution containing not less than 100 p.p.m. of available chlorine.

The strength of chlorine rinse waters is determined by a modification of the orthotolidine test.⁸ Inspectors carry a 2 oz. dropping bottle of orthotolidine solution, a 100 p.p.m. permanent chlorine standard in a sealed ampule, a test tube of the same diameter as the standard and graduated at 10 ml., and a medicine dropper calibrated to deliver 20 drops of water per ml. Ten ml. of tap water are added to the tube, followed by 4 drops (0.2 ml.) of the rinse water under test, and 1 ml. of the orthotolidine solution. After 5 to 10 minutes, comparison is made with the standard.

FIGURE 3

utes the bottle may be opened, when there will be a decided odor of hydrogen sulfide if sulfites are present. The test will detect as little as one grain of sodium sulfite in a pound of ground meat. Traces of sulfides in foods may yield false positive tests, and because of this the outfits are intended for screening tests only. All samples which show positive reactions are submitted to the laboratory for confirmatory analyses.

5. Arsenic Spray Residue—

The presence of excessive amounts of arsenic spray residue on fruits and vegetables is suspected when there are unusual deposits on the foods. In order to eliminate the detention of truck, boat, or railroad shipments pending laboratory examination, testing for arsenic is done in the field. The test used is an adaptation of the official Gutzeit method for arsenic of the A.O.A.C.¹⁴

Similar modifications have been used by others.¹⁵

The equipment designed for the sulfite determination in ground meat is also used for the arsenic tests. A piece of glass tubing is fitted to the Gutzeit scrubber tube to hold a strip of sensitized mercuric bromide paper. In addition, 15 ml. of 40 per cent stannous chloride solution is added to each liter of the 10 per cent sulfuric acid reagent. In practice the acid used for the sulfite test contains the stannous chloride addition and is thus also suitable for the arsenic examination. The details of the tests are indicated in Figure 4. The directions are essentially the same as in the case of the sulfite examination. Scrapings of suspected material are introduced into the generator. The acid and zinc are added and the reaction is allowed to proceed for 30 minutes. A decided yellow to dark brown color-

FIGURE 4

tion of the sensitized mercuric bromide paper indicates the presence of arsenic.

9. Food Utensil Swabbing—

The improved vials recently described by Buck¹⁶ are routinely used by the Baltimore City Health Department food inspectors to secure bacteriologic samples from drinking glasses and food utensils. The vials have a plastic screw type closure which holds a wooden applicator with cotton attached. Salt solution or broth is sterilized directly in the vials. It is possible for the inspector to carry a number of these small vials in his carrying case without fear of contaminating them.

10. Other Tests—

Other equipment may be added to the inspector's carrying case as needs arise, as for example, the Scharer modification of the phosphatase test for the

detection of proper pasteurization of milk and cream¹⁷ which is adapted to field use. Soft drink bottling plant inspectors may use an outfit for testing the alkalinity of wash waters. The foam test¹⁸ for renovated butter and oleomargarine may be carried out in the field by means of a spoon and an alcohol lamp.

DISCUSSION

More than 6,000 field tests have been made by the staff of the Bureau of Food Control of the Baltimore City Health Department during the past two years. The majority of these tests were examinations of chlorine rinse waters and food utensil swabbings. Other tests revealed that metal polish containing cyanide was in use in more than 200 food establishments, which led to regulations prohibiting its use. Field testing resulted in the condemnation of at least

50 lots of incipiently decomposed shucked oysters which could not have been readily detected by organoleptic means. Sulfite in ground meat is now rarely encountered, largely because meat dealers know that the Health Department has ready means of its detection.

The field test is never used as a basis for prosecution. The purpose and the intention of the field tests is to assist the inspectors' organoleptic senses and is not meant to supplant the more critical examination of foods by trained chemists. Inspectors are cautioned to use the field methods for information and screening purposes only and to submit samples to the Bureau of Laboratories for confirmatory analyses.

SUMMARY

A description has been given of the methods and equipment used by food inspectors of the Baltimore City Health Department for making selected analytical examinations in the course of inspections of food establishments.

Trends in Public Health Activities among Negroes in 96 Southern Counties During the Period 1930-1939

II. Comparison of Certain Health Services Available for Negroes and White Persons

PAUL B. CORNELLY, M.D., DR.P.H., F.A.P.H.A.

*Associate Professor in Preventive Medicine and Public Health, Howard
University College of Medicine, Washington, D. C.*

THE Julius Rosenwald Fund in the summer of 1940 made available a grant to the College of Medicine of Howard University for a 3 months' study of the trend in public health activities in relation to the Negro in the United States, which had taken place during the decade 1930-1939. In formulating the protocol for this investigation, an inquiry into the health situation among Negroes in the rural South was given a prominent place, since the Negro health problem, if there be such, is to be found primarily in the rural South. Therefore, letters and questionnaires were sent to 385 southern counties having full-time health units. The schedules requested information along these lines: first, Negro professional personnel employed; second, availability of certain health services according to race; and third, the personal reactions of the administrators of these health units to certain questions of opinion.

The analysis of the first of these three areas of investigations has already been published.¹ The present article is concerned with the second phase; namely, the trends in the availability of certain health services for Negroes as compared with whites during the decade 1930-

1939. The last of these analyses will be the subject of a subsequent paper. For a fuller discussion of the characteristics of the 96 counties studied, the reader is referred to the first article, since only one or two pertinent items which will serve to orient him will be mentioned here.

One hundred and seventeen, or 30.4 per cent, of 385 counties responded. However, of this number, 21 had to be discarded for failure to answer the questionnaire. Thus 96 counties, or 24.9 per cent, provided us with schedules which in part or as a whole could be used in this report. The distribution of these counties according to state is shown in Table 1. It is noted that Alabama had the largest representation of counties, with 24, followed by Florida, Louisiana, and Tennessee, with 10 each. Texas, Arkansas, and West Virginia are the only states not represented. Three counties responded from Texas but were not included because of the inadequacy of the information recorded. No questionnaires were received from Arkansas, while West Virginia was not circularized because of the small Negro population, which comprises only 8 per cent of the total in the state.

TABLE 1

Distribution of 96 Counties According to States

<i>State</i>	<i>No. of Counties Responding</i>
Alabama	24
Florida	7
Georgia	10
Kentucky	6
Louisiana	10
Maryland	6
Mississippi	5
North Carolina	7
Oklahoma	1
South Carolina	6
Virginia	4
Tennessee	10
Total	96

The 96 counties had a total of 3,765,183 population, of whom 1,371,572, or 36 per cent, were Negroes. This represents about one-tenth of the whole Negro population and one-seventh of that of the South. Hence, this sample is large enough to be somewhat representative of this section of the South. The population was largely rural, since only 16 of the 96 counties reported city-county organizations. The largest of these combined units was Jefferson County, Ala., which includes Birmingham within its boundary and gives this county a total population of 475,000 individuals, of whom 184,795 are Negroes.

COMPARISON OF CERTAIN HEALTH SERVICES AVAILABLE FOR NEGROES AND WHITE PERSONS

Unfortunately it was impossible to obtain enough information on all of the

health activities investigated from a sufficiently large number of counties to be representative at all times of this group. This is due to the fact that for the most part these health units do not tabulate much of their essential data according to color. This is to be regretted because this is one of the methods which help the health officer or any investigator to determine whether or not services are being made available or used according to the needs of particular groups in the population. Even though the limitation of the data must be kept in mind, yet certain trends may be observed. Furthermore, the paucity of material in certain spheres is an excellent argument for urging better collection and tabulation of the data which are daily gathered by health departments.

1. *Tuberculosis* — Tuberculosis at present is the seventh or eighth cause of death among whites, while it is first or second among Negroes. Therefore services should be developed in a larger measure for Negroes. This, however, does not seem to be the case.

Clinic facilities are an essential part in the tuberculosis case finding program and constitute a bulwark in the first line of defense against the disease. What has been the progress in this direction during the period 1930-1939? Table 2 provides the data for such a discussion. This table is arranged so that it presents in the first two horizontal tabulations a comparison of 17 counties which reported information for

both 1930 and 1939; while the last horizontal division considers all of the counties which recorded information for 1939, irrespective of whether or not they provided such data for 1930.

It is readily noted when the 17 counties are compared for 1930 and 1939 that in both periods the availability of clinic services for white persons was much greater than for Negroes, although the number of deaths was greater in the latter group. In 1930, Negroes scarcely received 1 clinic hour per week per 100 deaths, while the white population had almost 5. In 1939, the services increased for both groups, although much more for the Negro, so that the disproportion was cut in half, making this 2.5 to 1. Even though there was a growth in this sphere, yet there were a number of counties which still provided no clinic services. In 1930, of the 17 counties, 10 were deficient in this regard, while in 1939, 8, or 50 per cent, still reported this lack. When all of the counties with data for 1939 are considered, the picture changes very little. It is still found that 18, or half of the counties, had no clinic services either for Negro or white individuals. Although this is a relatively small sample, the fact stands out that Negroes are at present receiving less clinic service and there are still many counties without any services whatsoever.

The outlook is not much better when hospital facilities are evaluated. Here again, the condition in 28 counties which reported for both 1930 and 1939

may be studied in Table 3. As would be expected, the number of beds for white persons was greater than for Negroes in both 1930 and 1939. In the former year the 28 counties reported 0.08 beds per death for Negroes as compared to 0.18 for white persons while, in 1939, this had increased for both races, but the disproportion of two to one was still in the Negro's disfavor. Furthermore, neither for the white nor the Negro population was the minimum standard of one bed per death reached. It is also of interest to note that of the 28 counties, 25 in 1930 had beds neither for white persons nor Negroes, while in 1939, the picture had changed very little, so that 20 still reported no hospital facilities. When all of the counties which reported for 1939 are considered, the picture is somewhat more favorable, particularly for white persons, where the minimum of 1 bed per death appears to have been achieved; but for the Negro the situation is still of concern, since less than one-half a bed is available. It is to be noted also that, of the 61 counties, approximately 40, or two-thirds, reported no hospital facilities for either race.

It is beyond contradiction on the one hand to say that progress in tuberculosis control has taken place in the rural areas during the period of 1930-1939 and, measured statistically, this has been a two- to threefold advance. On the other side, however, it must be admitted that, in spite of too meager facilities and services, the tuberculosis deaths in many of these areas have con-

TABLE 3

Availability of Beds for Tuberculosis Care

Year	Counties Reporting	No. of Deaths		No. of Beds		Beds per Death	
		N	W	N	W	N	W
1930	28	517	358	40	60	0.08	0.18
1939	28	376	266	80	129	0.21	0.48
1939	61	682	470	279	547	0.40	1.16

tinued to decrease and that, as a whole, the Negro rates for the South are much lower than those for the North. The causes of this downward trend and this differential are not known, and it might well be of some interest to develop mass surveys in selected rural areas to gain a true insight into the tuberculosis problem among rural Negroes, just as has been done for syphilis.

2. *Venereal Diseases* — The Negro seems to fare somewhat better in the programs for venereal disease control. Comparing 32 counties in 1930 and 1939 (Table 4), it is found that, on

1930 and 1939; even so, there appears to have been marked progress in this field during this 10 year period. This same advance is of course to be noted when all of the counties which reported data for 1939 are considered. Here, again, the Negroes have twice as many clinic services as white persons. This forward march is also noted from another angle. In 1930, of the 32 counties, 17 did not have any venereal disease clinics for either racial group. In 1939, of the same 32 counties, only 4 reported in the negative. This is even better when all of the 63 counties reporting in 1939

TABLE 4
Venereal Disease Clinic Facilities in 1930 and 1939

Year	Counties Reporting	Population		Clinic Hours per Week		Clinic Hours per Week per 100,000	
		N	W	N	W	N	W
1930	32	421,025	826,535	64	60	15.2	7.3
1939	32	421,025	826,535	269	215	63.9	26.0
1939	63	951,855	1,674,222	519	413	54.5	24.7

the basis of population, the Negro had available many more clinic hours per week than white persons. In 1930, this was 15.2 per 100,000 for the Negro and 7.3 per 100,000 for white persons, or a ratio of two to one. By 1939, these services had increased almost fourfold for both groups, so that Negroes had available 63.9 clinic hours per week per 100,000, as compared to 26.0 for white persons. It must be kept in mind that the gains during this 10 year period may not be quite this much, since the same population totals were used for

are considered, for in this group only 4 had no clinic facilities for Negroes, but 8 had none for white persons.

This remarkable achievement during this decade must be attributed to the tremendous emphasis which has been placed on venereal disease control since 1935. One must not lose sight of the fact, however, that the proportion of facilities is not yet equivalent to the ratio of the venereal disease rate of Negroes to that of white persons. It has often been repeated for instance that six to ten times as many Negroes

TABLE 5
Prenatal Clinic Service Available in 1930 and 1939

Year	Counties Reporting	No. of Live Births		No. of Clinic Hours per Week		No. of Clinic Hours per Week per 1,000 Live Births	
		N	W	N	W	N	W
1930	21	7,545	9,555	13.2	9.3	1.9	0.9
1939	21	7,561	10,731	70.5	60.5	9.2	5.6
1939	27	11,441	21,945	148.5	131.0	12.9	6.2

have syphilis; therefore, a ratio of clinic services of two to one is still far short of the mark if need is the criterion of choice for the development of facilities. Also, it is to be emphasized that, even in 1939, almost 15 per cent of the counties had no clinical facilities for the control of venereal diseases.

3. Maternal and Infant Care—The problem of maternal and infant welfare is also of particular importance to Negroes, since their mortalities are generally twice as high as that of white individuals. According to Table 5, wherein 21 counties are compared for 1930 and 1939, it is found that, although Negroes had twice as many prenatal clinic hours per week for 1,000 live births as did white persons, yet the amount was far below the minimum of from 6 to 12 clinic hours per week per 1,000 live births suggested by Hiscock.² This was also true for the white population. By 1939, however, there was a sizable increase for both groups in the same 21 counties, so that Negroes received 9.2 clinic hours per week per 1,000 live births, while white persons obtained 5.6. Thus a five- and sixfold increase respectively was achieved for these two races in the decade 1930-1939, and the 21 counties in 1939 had apparently reached the suggested minimum level. This favorable position is also in evidence when all of the 50 counties which reported such services are analyzed. This advance certainly must in part be attributed to the recent stimulation given to maternal and child health programs through federal con-

tributions under the Social Security Act promulgated in 1935. Without such financial stimulation it is to be doubted whether this marked progress would have taken place. Again, a word of caution must be interjected here. In 1939, 16, or about one-third of the 50 counties, reported no prenatal clinic facilities either for white or Negro pregnant women. If this is the situation in full-time county health units, what then must be the outlook in counties with no such organizations?

The proportion of babies delivered in hospitals and by midwives and the number of midwives in the community are also measures of evaluation of maternal and infant hygiene programs. In these spheres the Negro suffers by comparison. In Table 6, the percentages of babies delivered in hospitals and by midwives is considered. Fifty-four, or 86 per cent of the 63 counties, reported that in 1939 less than 10 per cent of the Negro babies were born in hospitals. If this group is further analyzed it is found that 22 of the 54 counties, or one-third of the 63 units, had no Negro hospital deliveries in 1939. For the white population, on the other hand, only 21, or one-third of the counties, had less than 10 per cent of their white babies delivered in hospitals. Of these 21, only 6 counties reported no white hospital deliveries.

It has often been said that the majority of Negro babies in the South are delivered by midwives. This table supports this contention. In 1939, 13, or one-fifth of the counties, reported that

TABLE 6

Per cent of Babies Delivered in Hospitals and by Midwives in 1939

		Counties Reporting	Per cent of Babies Delivered in Hospitals					Counties Reporting	Per cent of Babies Delivered by Midwives				
			40 and										
			0-9	10-19	20-29	30-39	Over		0-19	20-39	40-59	60-79	80-100

	W	63	21	15	9	14	14	68	54	9	2	2	1

Number of Counties {

less than 20 per cent of their Negro babies were delivered by midwives; on the other hand, 80 per cent of the counties stated that this was true for white mothers. Furthermore, 26, or more than one-third of the counties, reported that 80 per cent of the Negro deliveries were attended by midwives, while only 1 county reported such a high percentage for white mothers. This condition is typical of practically the whole South, as shown by the report of the Bureau of the Census.³

The number of midwives in these counties is part of the whole picture and may be briefly described. In 1930, 57 counties reported a total of 2,938 midwives; these same counties in 1939 stated that they had only 1,943 of these individuals, or a decrease of more than 35 per cent. Using a population estimate of 943,274, we find that in 1930 there was 1 midwife for every 321 Negroes, while in 1939 this ratio had decreased to 1 per 485. This latter ratio holds true when all of the counties, 89 in number, reporting for 1939 are considered. With a total population in that year of 1,275,830 Negroes, they had 2,772 midwives, or 1 for every 460 persons. During the period 1930-1939, 8 of the 54 counties showed an increase in the number of midwives; 3 remained the same; 43 showed a definite decrease.

Registration and supervision are essential aspects in the program for continuous improvement of the midwife and therefore should be in force in every community. Of 87 counties, 80 have undertaken such a program, but 7 still neither register nor supervise their midwives. Of 71 which have this program of supervision, one-half instituted it during the decade 1930-1939; 3 previous to 1920, and the rest in the decade of 1920-1929.

It appears to us that for some time to come midwives, like poor relations, will always be with us; and certainly in many areas they fill a much needed

gap in the number of professional personnel and the availability of services. This being the case, every attempt should be made by all health units confronted with this problem to develop plans for their improvement. This should be done by supervision, classes, and inspections. In addition, the utilization of trained nurse-midwives will help in supplementing and aiding this service.

4. *School Hygiene*—It was very difficult to analyze the data in this sphere of activity because of the meagerness of the information received. This incompleteness may signify that such programs have not been fully developed and are in the rudimentary stages; or that data separated on the basis of race are not available. The former statement is no doubt the truer explanation, since Negro children, with the exception of mass immunization procedures, are as a general rule ignored in the formulation of school health programs.

The analysis of the data available shows that the health programs for Negro children consist in the main of visits by nurses. In 1930, of 37 counties, 21 reported that 100 per cent of the Negro schools were visited. However, in that year, 8 of the counties reported that Negro schools had not been visited, whereas the number for the white schools was 5. In 1939 conditions were somewhat better, since in 53 of 72 counties all of the Negro schools were visited and, for the white schools, the same held true in 61 counties. The number of counties reporting this deficiency in Negro schools was 5, while only 3 admitted such a lack in white schools.

The examination of school children is an important aspect of this whole program. Within itself it is an important educational procedure. In 1930, 12, or 40 per cent, of 30 counties stated that Negro children were not examined, while only half this number reported the same for white children. The rest of

the counties reported various figures ranging from 8 to 100 per cent. In 1939 some progress is noticed. Eleven of 58 counties reported that no Negro children had been examined, but for the white children only 1 county admitted this deficiency. Thirty-eight of the 58 counties examined 50 per cent or more of their white children, but only 23 reached this level for Negro children.

Dental services which may be considered part of this program show an even greater lag for both white and Negro children. In 1930 all of the 27 counties which reported on this phase admitted no dental services for Negro children. Of these same 27, 3 admitted having services available to white children; 1 had given services totalling 748 items; another relied on the State Health Department trailer, and the third had its own clinics. By 1939 this picture had changed a little for the better. Of 44 counties reporting, 12, or about 30 per cent, provided dental services for Negro school children. These 12 counties which are listed below reported an approximate total number of 5,500 items of service.

COUNTIES REPORTING DENTAL SERVICES
FOR NEGROES

1. Jefferson, Ala.
2. Orange, Fla.
3. Worth, Ga.
4. Caldwell, Ky.
5. LaSalle, La.
6. St. Martin, La.
7. Anne Arundel, Md.
8. Pitt, N. C.
9. Columbus, N. C.
10. Berkeley, S. C.
11. Hardeman, Tenn.
12. Albemarle, Va.

More services were, of course, available to white children in 1939. Of the 44 counties, 24, or more than 50 per cent, reported dental services for this group to the extent of 30,000 items.

Although progress is shown in the availability of dental services for Negro and white children, yet the amount of

services rendered is still very meager when compared with the total school population of these counties. This is particularly true in the case of Negro children. This problem, like others, needs to be attacked by health departments. The employment of more dental hygienists might partly solve this problem. This professional group could be used for screening children with defects while state or county trailers could engage in the follow-up work. These dental hygienists could also be used effectively for health education. Even though this approach appears quite feasible, nevertheless, there will always be two obstacles to the development of dental programs in schools: (1) the economic position of Negro rural families; and (2) the wide scattering of Negro schools in many rural communities.

Postgraduate Courses and Fellowships

—An attempt was made to discover the availability of courses and fellowships for Negro personnel in these health departments. As a whole they are not plentiful. In the decade of 1930–1939, of 83 counties only 1 had offered postgraduate courses for Negro physicians; only 1 had done so for nurses, and 6 had offered courses for others; mostly midwives. These counties were more generous in awarding fellowships. Of 84 counties, 5 had granted 8 fellowships to physicians and 6 had granted 7 to Negro nurses.

SUMMARY

Ninety-six southern counties with full-time health units were investigated by the questionnaire method in reference to the progress which had been achieved during the period 1930–1939 in certain public health services available to Negroes and white persons.

The analysis reveals that, during the decade in question, progress has taken place along several avenues, but this has been slow in pace and meager in quantity when compared to the number

and magnitude of the health problems facing Negroes in the rural South. Some advance has been made in the provision of clinic services for Negroes and white persons in these areas, but still too many communities are without adequate clinic facilities. This appears to be true particularly of truly rural counties with small populations. This fact has already been emphasized in a recent study which concluded: "Lack of clinic service to support the educational work of public health agencies is an outstanding deficiency of health organization especially for counties in the lower population group."⁴

Although tuberculosis is the foremost plague of the Negro, yet in this group of counties, he has available less clinic service and fewer beds per death. In the venereal disease field the Negro fares better—most likely as the result of the recent crusade—since he has twice as many clinic hours allocated to him per week as do his white brethren; but even this is not in proportion to the disparity existing between the incidence in the two races. The same outlook is to be found in the maternal and child health sphere. This study showed alarming neglect in the health supervision of Negro school children. In 1939, 11 of 58 counties reported no examination of

Negro school children, while only 1 reported this deficiency for white school children.

On the basis of the analysis and opinions expressed by county health officers one may state that, in addition to the needs of clinic services for venereal diseases, tuberculosis, and the prenatal and postnatal stages, there is also a dire urgency for the development of a comprehensive approach to the manifold health problems of the Negro. What has been gained, may we ask, in a public health way when it is recorded in the files that a man has received 20 injections of bismuth and 20 of neoarsphenamine, and therefore has been discharged as adequately treated for syphilis, if his nutrition is poor, his teeth are decayed, his health habits are atrocious, he is diabetic, and his house is not properly screened?

Evaluation of Health Services in a National Emergency*

JOSEPH W. MOUNTIN, M.D., F.A.P.H.A.

Assistant Surgeon General, U. S. Public Health Service, Bethesda, Md.

AGAIN I am back at the scene of my former activity in the public health field. One of my early assignments from the U. S. Public Health Service was to the State of Missouri. That was in the early 20's. In those days the disappointments and failures attending public health work far exceeded the actual accomplishments. Today, coming from Washington, I assume I am privileged to point with pride and view with alarm. I should like, with your permission, to do the former first.

If conditions today were less critical—if I were less actively identified with matters of immediate importance—I should like to spend this time reminiscing. I even believe we might derive some profit from such a backward glance. But reminiscences are hardly appropriate under present circumstances. Nevertheless, before passing on to a discussion of current problems, I should like to say a few words about the past.

When this association was formed, few had any idea that it would develop into the large and influential organization represented here today. At the early conferences, the speakers as well as the audiences consisted mainly of the founding fathers themselves. When compared with the many and complex tasks facing us today, the matters which concerned us then appear relatively

simple. Moreover, resources for public health activities were extremely limited. When I was sent to Missouri, the state biennial budget for such activities amounted to some \$60,000 or \$70,000. Actually, a large part of this amount was collected by the State Board of Health in the form of medical licensure and vital statistics fees, and went back into the state treasury. The board of health was vested by law with broad and equally vague powers and duties, but in fact it was an organization which passed upon applications for licensure and drew up resolutions upon which local governing agencies might act. In addition, it performed the rather prosaic function of collecting records of births and deaths. The local health officer was a part-time official who held nominal office and who was appointed merely in order that the statute might be fulfilled.

My function as a federal official detailed to Missouri was to stimulate a movement for expanded local health organization. I might better say that my function was to explore the basis for such a movement and to seek out the local resources for getting it under way. I did not come as a Santa Claus bearing offerings and material assistance from Uncle Sam, in the manner of federal officials today. At that time my organization, the U. S. Public Health Service, felt it was extending itself to the utmost by sending one young, inexperienced officer to give such advice and moral support as he could. From that point on, the job consisted chiefly of per-

* Presented before the Missouri Public Health Association at the 18th Annual Meeting in Kansas City, Mo., May 8, 1942.

suasion, of beating the bushes for any and every kind of facility or support, and getting local appropriations.

Since those early days the public health services of this country have been greatly extended and improved. Increasing state and local determination to face health problems effectively has been supported by substantial financial aid from the federal government. Instead of a biennial budget of \$60,000 or \$70,000, state funds budgeted for public health activities in Missouri during the current fiscal year alone amount to approximately \$170,000. This sum is augmented by local funds totaling \$1,073,000. In addition, federal funds budgeted for health services during the year amount to slightly more than three-quarters of a million dollars. Thus, the total annual public health budget in Missouri for the present fiscal year is approximately \$2,031,000.

Missouri has done better than some states and not so well as many others in contributing to its own development. The health organization of the country as a whole is still highly uneven. Of the 3,070 counties in the United States, 1,669, or about 54 per cent, were organized under some form of full-time local service on June 30, 1941. For the most part, these organized counties are the populous ones; therefore the proportion of the population served is much greater than the proportion of jurisdictions involved. Since June 30, 1941, full-time service has been extended to more than 100 additional counties. The total coöperative health budget for the fiscal year 1942, including federal, state, and local funds, as reported to the Public Health Service, is almost \$119,000,000.

Of course, there is room for a great deal of improvement. The fact that more than one-half of our counties are covered by full-time local services conveys a mistaken impression unless it is pointed out that in many counties only

limited services are performed by skeleton organizations which may be said to have little muscle covering the bones. But this is no time to recount past successes and failures. Nor is it a time to plan for the future in terms of the progressive evolution which has characterized the development of most of our American institutions.

We are now engaged in a no-quarter battle with an enemy who scorns these institutions and who is doing the utmost to insure that they will play no further part in world history. Whether we win or lose depends upon how quickly and effectively we can organize the entire nation with all its resources and skills for one supreme, coöordinated victory program. The public health organizations of this country can no more escape the consequences of this total mobilization than can any other segment of national life. It is true that health services must be extended to many regions which formerly had few inhabitants but which are now teeming centers of military or industrial activity. But a more immediate responsibility, and one which has even greater bearing on the future of our country, is the fullest possible utilization of the public health structure now existing in the more populous sections of the nation.

This means that health departments must subject every aspect of their programs to scrutiny in terms of war-connected need. Cherished plans may have to be given up, and projects which cannot be justified directly as war measures may have to be abandoned. Accustomed ways of doing things will have to be altered so that things can be done quickly. I do not need to tell you how late we are as a nation in getting this type of conversion under way. The reverses suffered by our armed forces and those of our allies is ample evidence of our tardiness.

While curtailment of certain activities will be necessary, prompt and vigorous

undertaking of many new activities is imperative. I believe it is correct to say that no other type of agency is better adapted organizationally and legally to the assumption of these emergency duties than the health departments. A declaration of the American Public Health Association, adopted in December, 1941, states:

"The effective modern health department, as now conceived and at present organized in many states, cities, and counties as a branch of civil government, comprises a medical, sanitary, and related biological and social competence which enjoys broad authority to meet a wide variety of medical and environmental emergencies. . . . the health officer and his staff must be alert to extend, and, if necessary, to modify the usually accepted health functions to meet the multitude of exceptional situations certain to be created by the state of war and by the mobilization of all the people and their industry to support the armed forces."

This is a call for direct action, for the assumption of larger responsibilities, and for greater vigor in all essential activities. In recent years, health departments have sought to accomplish results chiefly by means of persuasion. Such a method may have been appropriate when we could afford to proceed on the assumption, however fallacious, that people had only to be told what to do and that somehow or other the wherewithal to do it would be forthcoming. The time when we could proceed on such a basis, however, is gone, and it may never return—at least not in our generation. Today, direct administrative action is required; the processes of education are too slow. Free enterprise cannot be expected to adjust itself automatically to a situation which is national in scope and character, or to undertake on its own initiative action which does not serve its own immediate interest.

What are the "exceptional situations" referred to in the declaration of the American Public Health Association which I just quoted? First, I would call attention to the matter of law enforcement. As stated by the declaration, the authority granted to health departments is very broad. While it may be said to the credit of health agencies that they have not abused this power, they may, on the other hand, justly be condemned for not having exercised it sufficiently when needed.

Today people are literally begging to be directed in constructive action which will promote success in the war. The various polls and barometers of public opinion consistently show that the people as a whole are far ahead of the framers of public policy in their willingness to surrender customary rights and privileges for the common cause. But, in order to make use of this popular disposition to sacrifice and help, some form of organizing and directing authority is needed. I am sure that if health departments merely undertook aggressive enforcement of existing laws and regulations, if they made use of the authority already vested in them, many of our most vexing problems would be resolved immediately.

This type of action does not require the time-consuming conferences and surveys which have constituted such a large part of the work of health agencies during the past 25 years. Needs have been established which we could not meet in peacetime, let alone now. A recent study of selective service physical examinations in Hagerstown, Md., showed that physical defects for which selectees were disqualified had been discovered in school surveys years before. Recommendations for correction of these defects had been made, but nothing had been done in most cases. Unless the means are at hand to correct the conditions uncovered by surveys, there is certainly no justification for

conducting them at this time. Health departments might better devote their attention to conditions which they are in a position to remedy.

This brings me to a fundamental fact which I have been emphasizing for years. That is, the health of the community rests on two basic factors: environmental sanitation and medical service.

We want sanitation, and we must have it. I have already mentioned how much could be accomplished in this respect by adequate law enforcement. But we cannot overlook the fact that, in order to put many premises into good sanitary condition, construction and installations are necessary. At the present time this brings us face to face with the many restrictions imposed on the procurement of materials, supplies, and labor. In making recommendations to property owners and occupants, these restrictions must be kept in mind. There is little point in telling a dairyman to install stainless steel pasteurizing equipment or in advising a restaurant owner to put in a mechanical dishwasher when these products have been taken off the market. We had sanitation before many of our modern improvements came into being. Until the new and improved products are available again, we will have to make the old ones do. I will even venture the possibility that before this war is over some of our sewage may again have to be carried in open ditches.

As the war progresses, the shortage of physicians, dentists, nurses, and the various technicians who play a part in medical service will become increasingly acute. Time will not permit me to dwell on methods of meeting shortages of personnel in all the professional branches, but what I say about physicians will apply to the others as well.

Many communities will be depleted of the physicians now practising there. In scarcely a town will there be found the empty waiting rooms which we

heard so much about a few years ago.

What are you going to do about it? Traditionally health departments have not concerned themselves with problems of medical care, except in so far as they are related to certain diseases and certain limited groups in the population. Today, however, the national interest requires broader participation in this form of activity.

In many places throughout the country large military camps have been established in sections where facilities for medical care are lacking or inadequate. The safety of both military and auxiliary civilian personnel requires that this need be met. The same is true in communities now devoted to the manufacture and assembly of essential war materials. The people working in these communities must be kept in good health and at a high level of efficiency. If a machine is idle because the worker who should tend it is sick, that machine is doing a job for Hitler. Yet, today there are such communities without physicians, and there are others where the ratio of physicians to population is as low as 1 to 3,000. Hours which could be devoted to work are spent in crowded waiting rooms of doctors who are perhaps too busy and exhausted to give satisfactory care. Worst of all, under such circumstances, days and weeks of valuable working time are lost when neglected minor ailments result in serious illness.

Then there is that vast reservoir of young man power now kept from active military duty because of remediable physical defects. Rehabilitation services which will make these men available are needed at once. It is recognized, of course, that doctors cannot be trained and provided in a few months' time. The obvious way of meeting the situation, therefore, is to streamline and utilize whatever resources we now have, to organize medical service around clinics where necessary, and to supple-

ment the higher skills with lesser ones. In short, in these critical localities, medical services must be developed on a wholesale rather than a retail basis. The official health agencies must initiate or at least take an active part in the reorganization of medical services wherever present deficiencies interfere with war work. The same applies to the provision of hospital facilities. In many instances health agencies may have to engage in direct operation of hospitals. They may also be called upon to operate new or expanded sanitation facilities.

The people of the nation quite naturally look to the health departments for technical assistance in the organization and operation of civilian defense programs. Here is a new field of endeavor involving many time consuming obligations. But it is also a field which presents unparalleled opportunities for enlisting public coöperation and support.

Unfortunately it is customary to think of additional personnel as a natural corollary to additional duties. Not only are larger staffs impossible at present, but health departments may expect to lose many of the professional workers they now employ. These workers—physicians, nurses, and engineers—all possess experience and skills urgently needed by our fighting forces. They cannot be retained in their present capacities simply because they are performing socially useful work. Unless they are actually doing work that is *more* important than what they could be doing with the armed services, the health department has no right to retain them.

How then are the increased duties to be performed? It is obvious that everybody will have to work harder. I doubt if anyone will object to that. But when I say that it will also be necessary to employ substandard or partially trained personnel, I am not so sure but that complaints may be forthcoming. Nevertheless, it is the only

way the task can be done, and it must be done. At the present time, maintenance of the highest possible type of health services is not the chief consideration. The important thing is to see that necessary services *are* performed with whatever types of workers and facilities are available. Present well qualified staffs of health agencies must concentrate on training and supervisory activities, and routine duties must be performed by those with less skill and experience. The extent to which this dilution process will have to be carried out cannot be foreseen. It depends on the duration of the war and the demands of the army, navy, and war industries.

I am not proposing that merit systems of personnel administration, laboriously evolved, be scrapped. That is not necessary. The situation can be met by the creation of interim classifications, permitting the employment of substandard personnel for the duration of the emergency.

The health agencies of the country may not be permitted much longer to decide whether certain tasks should be done or not. If the tasks in question are essential to victory they will be done—if not by the health departments, then by some other agency or agencies. That is the only way in which the future of our country can be assured. And I believe it is fair to say that the future pattern of public health organization of this country will depend upon how health departments meet the challenge of the present situation. Either they will emerge from the war as stronger, more useful, and more respected servants of the common weal, or they will have been eclipsed by others who forged ahead while they lagged along at the usual pace.

Undoubtedly many of you are a bit dismayed by the magnitude of the tasks thrust upon you by the war. I wish, however, to call your attention to an-

other aspect of the situation. I believe you should consider yourselves both privileged and honored by the vital rôle assigned to you in seeing the nation through the most critical period of its existence.

You will have to endure many

trials and disappointments. You may have to expend the last ounce of your energy in the service of your country. This, however, has always been the lot of men and women in key positions during the crucial periods of history.

Reports on Food Habits Available

THE attention of the Association has been called to the fact that the Committee on Food Habits of the Division of Anthropology and Psychology, National Research Council, 2101 Constitution Avenue, Washington, D. C., has available reports which will be of interest and concern to a variety of persons dealing with populations having national or racial food habits.

Among the reports available are the following:

"Italian Food Patterns and Their Relationship to Wartime Problems of Food and Nutrition."

"The Relative Effectiveness of a Lecture Method and a Method of Group Decision for Changing Food Habits."

"A Group Test for Determining the Anchorage Points of Food Habits."

Also conferences of the Committee on Food Habits relating to the contributions from the fields of child development and market research.

Vaccine Prophylaxis against Tularemia in Man

L. FOSHAY, M.D., W. H. HESSELBROCK, H. J. WITTENBERG,
M.D., AND A. H. RODENBERG

*Department of Bacteriology, College of Medicine, University of Cincinnati,
and the Cincinnati General Hospital; and the Health Center,
Department of Health, Cincinnati, Ohio*

IT is characteristic of tularemia that most patients develop a high degree of natural resistance after infection occurs. The mortality is low. Recovery confers lifelong immunity which protects against subsequent massive exposures with an effectiveness seldom encountered in bacterial diseases. Second attacks of disease are unknown. Local reinfections occur occasionally among immunes subjected to repeated exposures to virulent strains but, as Francis first indicated, they are either asymptomatic or associated with brief and mild constitutional symptoms.¹ One of us has recorded apparent immunity, due to vaccination, which successfully withstood accidental massive exposures to strains of high virulence.²

Although tularemia is of minor importance as a cause of death it has considerable social and economic importance in areas of high endemicity as a cause of prolonged morbidity and disability. Its capacity to disrupt normal activities of military encampments is recognized.³ The extreme ease with which infection is acquired, and the high infection rates among butchers and market men, scientific investigators, rabbit hunters and their wives and cooks who prepare game for the table, indicate the desirability of better methods of protection than those now in use.

Preliminary experiments with heat

killed and formalinized *Bacterium tulareuse* * suspensions demonstrated clearly that vaccines made by these methods, from either virulent or avirulent strains, provoked severe and extensive constitutional and local reactions upon initial injection into normal individuals. Reasonably well tolerated doses were so small that several months of daily injections were required to produce agglutinin titers to 1:320, a scheme tolerable for a few laboratory workers but impracticable for large scale use.

The successful efforts of Ramon and his associates to diminish primary toxicity of toxins and of various bacteria without significant impairment of their antigenicity, by various chemicals, led us to try similar methods. We established the following specifications for an acceptable vaccine:

1. It should be capable of subcutaneous administration, being well absorbed and not producing sterile abscesses.
2. Toxicity upon initial injection must be diminished to a degree to permit a three injection scheme of administration.
3. The three doses must contain enough bacteria of sufficient antigenicity to confer protection.
4. Such doses must provoke no constitutional reactions nor severe local reactions.
5. The mode of preparation must be readily and reliably reproducible.

* Under the rules of uniform nomenclature adopted by the American Journal of Public Health, the name of "tularemia" should ordinarily be classed as "tularemia".

After many trials on human volunteers with vaccines made by a variety of chemical procedures the vaccine which best satisfied our criteria was one made by oxidation of virulent strains by nitrous acid. This vaccine was adopted in 1932.

PREPARATION OF THE VACCINE

a. *Selection of cultures*

Only strains of high virulence were used. Virulence was maintained by frequent serial passage in guinea pigs, killing all animals within 96 hours after cutaneous inoculation. Virulence for rabbits was not determined regularly. Occasional trials showed that the strains used killed these animals within 5 days after cutaneous inoculation. Virulence was titrated regularly in white mice. Serial dilutions were made from a saline suspension having a turbidity equivalent to that of 500 p.p.m. of a fullers' earth standard (T-500). The acceptable range of virulence was that which killed all mice, in lots of 5, in dilutions of T-500 $\times 10^{-7}$ to 10^{-9} , in 0.5 ml. intraperitoneal doses. The average mouse virulence was T-500 $\times 10^{-8}$.

During the first few years vaccine was made from eight strains. Since no antigenic strain differences were recorded, or found here, we used for three years a vaccine made from a single strain. Thereafter, with possible unknown strain variability in mind, the vaccine was composed of equal parts of four strains.

b. *Preparation of suspensions*

The 48 to 72 hour growth on blood-glucose-cystine agar was harvested in salt solution and filtered through cotton to remove particles of media. By collecting growth from several bottles or many tubes into one volume of salt solution an initial turbidity varying from T-12,000 to T-25,000 was secured. Turbidity was accurately determined and recorded, and the volume of sus-

pension carefully marked. Tubes were then centrifuged until the supernatant was clear, after which it was discarded.

c. *Oxidation procedure*

For each 3 ml. of packed bacterial sediment 5 ml. of freshly prepared 30 per cent aqueous sodium nitrite was drawn into a finely tipped pipette. The bacteria were suspended uniformly in this solution by repeated expulsions through the pipette. Five ml. of 30 per cent acetic acid was then added. This solution was made on the assumption of glacial acetic as 100 per cent. For larger volumes of bacterial sediment the nitrite solution was added in proportion of 3:5. The volume of acetic acid solution was always equivalent to that of nitrite solution.

After addition of acid, evolution of gas was noted at once. The tubes or centrifuge bottles, carefully marked for original volumes, were stood at room temperature for 4 hours. During the course of the study it was found that oxidation for 4 hours produced maximal diminution in toxicity consistent with minimal loss in antigenicity. Removal of acids and salts was facilitated by adding sterile distilled water up to convenient capacity of the receptacles. For the first two washings this shortened the time for quantitative centrifugation of cells. Four washings were needed to remove all traces of acid. Sterile saline was used for the last two washings. Thereafter the bacteria were thoroughly resuspended in 0.5 per cent phenolized salt solution up to the marks of original volumes. Chemical treatment alters so greatly the refractive index of bacterial suspensions that turbidity measurements must be made prior to oxidation.

d. *Completion of the vaccine*

In accordance with initial turbidity readings each tube was then suitably

diluted with phenolized saline to produce a final theoretical turbidity of T-6,000 which is approximately equivalent to a density of 24 billion bacteria per ml. After the usual tests for sterility the vaccine was bottled and stored at 4° C. until needed.

Keeping quality at storage temperature is limited. When diluted 1:60 and used to provoke cutaneous reactions in infected or recovered individuals a sharp falling off in reactivity was noted after 13 to 15 months. We made a fresh supply each autumn and marked expiration date for 12 months.

METHODS OF STUDY OF THE VACCINATED GROUP

Selection of individuals

Vaccine was administered only to susceptible individuals exposed to risk of infection. Selection was entirely at random, and on a volunteer basis. Prior to 1937 a considerable proportion of the vaccinated group was composed of those occupationally exposed; butchers, market men, professional rabbit hunters, and seasonal game handlers. In 1937, a municipal ordinance prohibited the sale of wild rabbits. Since then there has been no occupationally acquired tularemia in Cincinnati; a record contrary to previous experience. Food handlers had no further need for vaccine. Coincidentally there was a great increase in requests for vaccination of amateur rabbit hunters, their wives and cooks. Thus the composition and probable exposure risk of the vaccinated group were significantly altered.

During the entire period of vaccine preparation all laboratory personnel handling virulent cultures and infected animals were vaccinated.

Vaccination records

Duplicate records were kept of all vaccinated individuals. The items recorded annually were: name, age,

address, occupation, history of previous tularemic infection, the usual annual game bag, last year's total of rabbits killed; the dates of inoculation, size and number of doses, turbidity of vaccine, local and general reactions; also the results of agglutination tests and cutaneous tests, and notation of acquisition of tularemia after vaccination, with laboratory data.

Detection of recovered immunes among applicants

For reasons which will appear later great care was exercised to avoid giving vaccine to all who had had tularemia. Careful inquiry usually sufficed to detect recovered individuals, even though some did not know they had had "rabbit fever." When there was a dubious history we resorted to agglutination tests or cutaneous tests, withholding vaccine until final judgment could be made. In our hands these tests proved to be reliable indices of past infection.

Agglutination tests

Information concerning antigenicity of the vaccine was obtained by serum agglutination tests. By random selection individuals were examined for agglutinins each year. Eventually these results were grouped according to: (1) tests performed after initial vaccination, (2) tests prior to revaccination, and (3) after revaccination.

Detection of tularemia in the vaccinated group

Searching inquiries were made each year to discover tularemic infections among the vaccinated group. Since the laboratories of the Department of Health and of the Department of Bacteriology maintained free diagnostic services the great majority of all cases of tularemia were reported directly to us. Due to their own interest in the experiment most vaccinated individuals

promptly reported the occurrence of infectious disease. We believe our case finding methods disclosed every case among the vaccinated group, as well as the overwhelming majority of all cases in the community.

Study of the cases found

Every vaccinated individual who contracted tularemia was carefully observed with special reference to severity of infection, occurrence of visceral lesions, and duration of the various measurable clinical aspects of the disease for which we had control morbidity data.

Cases which occurred among vaccinated laboratory personnel were also studied carefully, and will be considered separately.

Administration of vaccine

Although the adoption of a maximal turbidity, and of a standard oxidation period, had to wait until experience indicated what was optimal the mode of administration remained uniform. Three doses of 0.5 ml. each were injected subcutaneously and alternately into the arms, on either consecutive or alternate days. It was found advisable to complete administration within a 6 day period. A delayed third injection fre-

quently provoked constitutional reactions and unduly large local reactions. Otherwise constitutional reactions were extremely rare, and local reactions were moderate. The necessity for lay-off from customary work did not arise. During the past five years this standard dose contained a total of 36 billion bacterial cells. The ratio of the tolerance dose of this vaccine to that of formalinized vaccine is 1,200:1.

Revaccination dosage

No constitutional reactions were observed upon revaccination prior to the introduction of the T-6,000, 4 hour oxidized vaccine. After its adoption, constitutional reactions were provoked by the initial dose of 0.5 ml. of the second annual series in about 60 per cent of individuals. This necessitated revision of the schedule for revaccination. Thereafter all applicants were given a trial first injection of 0.25 ml. The second and third doses varied in accordance with appearance and degree of reactions. If both general and local reactions were marked, no more vaccine was given that year. If there was no general reaction but marked local reaction, the subsequent doses were 0.25 ml. each. If neither general nor undue local reaction occurred the subsequent

TABLE 1

TABLE 1 shows for each year the turbidity of tularemic vaccine used, its duration of oxidation, number of persons vaccinated and revaccinated, and the maximal number exposed to risk of infection.

Vaccination of Applicants

Year	Vaccine		Applicants		Percentage Revaccination for Each Year	Cumulative Total of Individuals Vaccinated
	Turbidity	Hours Oxidized	Vaccinated	Revaccinated		
1931	1,000	16	72	0		72
1932	3,000	16	267	15	0	339
1933	3,000	13	48	8	14	387
1934	3,000	4	106	21	17	493
1935	6,000	4	123	53	30	616
1936	6,000	4	118	84	42	734
1937	6,000	4	232	176	19	1,466
1938	6,000	4	224	391	58	1,637
1939	6,000	4	458	339	43	2,145
			2,145	597		

doses were 0.5 ml. each. This plan gives maximal protection at minimal physiologic cost. Variations in density and oxidation periods of the vaccine are shown in Table 1.

Vaccination of recovered immunes

It is unnecessary and inadvisable to vaccinate persons who have recovered from tularemia. Since they are already protected for life the general and local reactions of unusual severity which inevitably follow serve no useful purpose. Since residual serum agglutinins are almost invariably present after recovery, and since cutaneous sensitivity is almost always present for many years thereafter, accurate methods for the detection of immunes are readily avail-

chills and sweats, agonizing headache, and intense pains in all muscles and joints. He exhibited alternation between hypomanic activity and confused, stuporous delirium. On the 3rd day the general reaction abated, and after the 4th day recovery was prompt and uneventful. At the height of reaction the entire upper arm was enormously swollen, presenting the picture of a severe Arthus reaction with central pallor and liquefaction necrosis. The regional axillary nodes were large, painful, and very tender. The local reaction persisted for 9 days.

Agglutinin titers after vaccination

Serum agglutination tests were performed by the standard macroscopic method. Figure 1 shows the titers observed in 79 individuals after initial vaccination. Blood samples were taken from the 6th to the 44th day after the third injection, the majority from the 10th to the 18th day, the largest number on the 14th day. Under these conditions agglutinins were present in 92 per cent of sera. Positive titers ranged from 1:10 to 1:640; the greatest number being 1:40. Highest titers were obtained during the 3rd week after vaccination.

FIGURE 1

Agglutinin titers after initial vaccination: 79 individuals.

able. Where agglutination tests cannot be had, the vaccine should be diluted 1:60 with salt solution and injected intradermally in 0.05 ml. amount, and the site examined 48 hours later.

Although we exercised great care to avoid vaccinating immune persons we committed this error five times. The reaction of one man was typical of all. Eight hours after injection he had a severe chill, a splitting headache, and severe bodily pains. The temperature was 104.8° F. After an hour he vomited, and continued to vomit even water for the next 48 hours, during which fever continued with recurring

FIGURE 2

Agglutinin titers after revaccination. 102 tests.

Agglutinin responses after one or more revaccinations were measured in sera obtained from the 2nd to the 48th day. The largest number of samples was secured during the 3rd week after inoculation. Agglutinins were present in 93 per cent of sera. Positive titers ranged from 1:10 to 1:320; the greatest number being 1:20, as shown in Figure 2.

Persistence of agglutinins provoked by vaccination

Since naturally acquired immunity is accompanied by persistence of serum agglutinins we measured the residual titers one year after vaccination. Figure 3 shows the titers found in 138 tests of sera obtained just prior to revaccination. Agglutinins were present in 56 per cent of sera. Positive titers ranged from 1:10 to 1:160; the largest number being 1:10.

FIGURE 3

Agglutinin titers 1 year after vaccination. 138 tests.

Evidence for immunity derived from constitutional reactions

Constitutional reactions were provoked only by revaccination, not by initial vaccination unless the last dose was delayed beyond the recommended interval. Although the intensity was much lower, the character of these reactions was identical with those produced by vaccinating an immune person. This suggested that some degree of residual immunity persisted for at least one year in about 60 per cent of those vaccinated. The agreement observed between the incidence of constitutional reactions occurring after revaccination (60 per cent) and the proportion of residual serum agglutinins (56 per cent) supported this suggestion, since almost every person who suffered a reaction had yielded serum, secured just before revaccination, which showed residual agglutinins.

Optimal time relation between vaccination and exposure

Experience does not permit a definite statement concerning the optimal time for prophylaxis in relation to anticipated exposure. Maximal agglutinin titers occurred 3 weeks after vaccination but it does not follow that maximal protection was conferred then. The majority of our people were vaccinated from 3 to 4 weeks prior to exposure. A number considerably in excess of 200 received vaccine within 48 hours of first exposure. None acquired the disease. Eight physicians, not included in the group under discussion, were vaccinated during possible incubation periods. Each had been contaminated, on the hands or in the eyes, with infected human exudates. None acquired the disease. We cannot say that any person in either of the above groups would have acquired the disease had he not been vaccinated. The risk was high but not certain. It was demonstrated that vaccination just prior to or im-

mediately after exposure did not have any adverse effect. In one instance we unwittingly vaccinated a hunter during the incubation period of a naturally acquired infection. Since he was febrile for only 8 days, never went to bed, and never laid off work for even a day, the effect in this patient was significant amelioration and shortening of the disease. We recommend that prophylaxis be completed at least 3 weeks before the anticipated exposure, but that there need be no fear of inducing harmful effects by administering vaccine immediately prior to exposure or during the incubation period.

Observations on the exposed vaccinated group

In the manner outlined above susceptible exposed individuals were vaccinated each year from 1933 to 1941, inclusive. In all, 2,145 persons were vaccinated. This number is exclusive of all professional groups or individuals. Table 1 shows the numbers of persons vaccinated and revaccinated, and the maximal number exposed to infection, during each year.

It was not possible to establish a control group of equivalent size consisting of persons given injections of inactive solutions or of heterologous vaccines. Even had we been able to do so we could not have obtained any precise knowledge of the relative exposure rates.

Exposure risk

If the ordinance forbidding sale of wild rabbits in local markets had not been passed we could have established relative exposure rates and disease incidence rates for the vaccinated and unvaccinated occupationally exposed groups. The total numbers of game handlers, of recovered immunes, and of wild rabbits handled each year were known. However, sales were stopped before the number of individuals in-

involved and the duration of their experience were large enough to be significant. The impossibility of control of many important variables left us unable to estimate the exposure risk of hunters and housewives who formed the balance of the experimental group. Considerable information was acquired concerning the total number who hunted each year, the number of rabbits killed per year per hunter, the average infection rate among rabbits, and so forth; but in our opinion no manipulation of these figures would yield defensible data.

Fourteen vaccinated persons acquired tularemia. Table 2 shows the relation of these cases to the annual prevalence of disease, and its severity, among the general population in the area which supplied the vaccinated group. No inference concerning the relative incidence of disease can be drawn since the total number of exposed individuals in the general population is unknown. The figures are presented to show that tularemia occurred in this area during every year that the exposed vaccinated group was observed, and that the infecting strains were sufficiently virulent to give a case fatality rate of 7.6 per cent for the 9 year period. Absence of cases among vaccinated persons in 1939 is probably a reflection of the abnormally small number of rabbits found that year, a fact which also best explains the unusually low incidence of disease. In regions where almost all human cases derive from contact with wild rabbits it has long been known that annual prevalence of tularemia depends upon the size of the rabbit population and the infection rate among rabbits, the latter varying chiefly with the total rabbit tick population and the tick infection rate.

It may be significant that during the large regional outbreak of 1936, with 140 cases and 8 deaths, only 1 case occurred among those vaccinated. All

TABLE 2

In Table 2 for each year are shown the maximal number of vaccinated persons exposed to infection, incidence of tularemia and of deaths among those vaccinated; also, the tularemic morbidity and mortality in the unvaccinated population of the same region.

Year	Experimental Group			General Population (size unknown)

Evidences of protection conferred by vaccination

The incidence of tularemia in the vaccinated group, though less than that anticipated, does not give reliable evidence of protection. More convincing evidence of the value of vaccination was obtained by study of vaccinated individuals who acquired the disease. Table 3 shows the intervals which elapsed between vaccination and infection.

During the course of this study one of us collected quantitative data on the measurable aspects of morbidity from 518 patients who had no treatment other than the usual symptomatic or expectant measures. These were collected to provide a standard American morbidity experience against which the results of any form of therapy or prophylaxis might be compared quantitatively. An analysis of these data,

demonstrating their appropriateness for such use, has been published.⁴ Table 4 shows comparable morbidity data from the 14 vaccinated, infected patients. The order of cases is the same as in Table 3.

Disability was measured by the number of days full-time work was not performed. Three patients worked uninterruptedly, and 4 others were disabled for 14 days or less. Nine were disabled for less than a month. The chief cause for prolongation of disability was suppurative lymphadenitis. In case 3 there was serial suppuration of twelve nodes. Pneumonia, with dry pleurisy, occurred once, in case 14. In over half of the cases fever was not only greatly shortened in duration but markedly ameliorated in degree, maximal temperatures being 102.5° F., or lower. In 10 patients there was striking amelioration of the customarily severe initial general symptoms, headache, arthralgias, myalgias, sweats, anorexia, and nausea. This was particularly impressive in those patients who

TABLE 4

Morbidity values were measured by the same method used for determination of morbidity constants in 518 control patients.⁴ The low incidence of suppurative lymphadenitis in the next to last column has little significance in a series this small.

Duration of Measurable Aspects of Disease in Vaccinated Infected Patients

did not receive serum therapy. It should be noted that in general the shortest and mildest infections occurred in those who had had the most vaccine, and for whom the intervals between vaccination and infection were not longer than 3 months.

Seven patients received serum therapy. Indications for use of serum were presence of pneumonia, initial symptoms of usual severity, unusually large number of large buboes in the first week (with the hope of lessening disability due to suppurations), or the desire to ameliorate symptoms and shorten the duration of illness. It is probable that serum treatment contributed to the favorable modification in the course of disease indicated by the figures in Table 4. Re-grouping of data to permit comparison between patients who received serum and those who did not is shown in Table 5. Those who re-

ceived no specific treatment exhibited significant amelioration and shortening of the disease.

A rough comparison of averages from the vaccinated infected cases with means from a large control group is shown in Table 6. Although durations of some aspects of morbidity were one-half to one-third of those for the control group, the small size of the vaccinated series does not justify overemphasis of the apparent value of vaccination, even though the probability of finding 14 consecutive cases of tularemia with such small morbidity constants by random selection is very remote.

Other evidence indicative of protection was obtained. Two identical experiences occurred several years apart, in which vaccinated susceptible butchers skinned and cleaned one rabbit for each of two customers. For each of the cus-

TABLE 5

Morbidity data regrouped with relation to specific serum treatment. The differences between the averages are probably not significant. The more severely infected patients received serum therapy.

tomers the rabbit was the only exposure to infection. Both butchers remained well; each of the customers acquired tularemia. Similar experiences were reported many times by members of hunting groups. Those previously vaccinated remained well, even though they cleaned all rabbits shot by the party, whereas one or more of the unvaccinated members contracted tularemia several days later.

Experience with vaccinated laboratory workers

Work with virulent cultures of *B. tularensis* does not carry much risk of infection but it is well known that handling infected animals and carcasses entails great risk, amply confirmed by the large number of laboratory infections acquired by well trained, experienced investigators.

Since 1929 our laboratory has had 9 persons exposed to tularemia by the handling of infected animals or, very recently, of virulent cultures in liquid media. Four of us have been exposed for 12, 8, 7, and 3 years, respectively. Two others were exposed for 2 years each, and the last 3 for 1 year each. Our original plan was to administer vaccine to each exposed person annually in the fall. During recent years, when

the risk of contamination was known to be very high throughout the entire year, supplementary small injections of from 0.10 to 0.25 ml. of the vaccine were given every 3 or 4 months.

By oversight an animal caretaker who assisted in inoculating hundreds of animals annually was not vaccinated during the 2 years following his initial series. Vaccine was given in 1938, but inadvertently omitted in 1939 and 1940. He acquired the typhoidal clinical type in 1940, developing pneumonia and considerable pleural effusion. *B. tularensis* was recovered by blood culture on the 16th day of disease, the day serum treatment was instituted. He was ill for 1.8 months, disabled for 2.3 months, in bed for 29 days, of which 22 were febrile days. The serum agglutinin titer was complete in dilution of 1:10,240 on the 40th day after onset. Recovery was uneventful.

For the rest of us who received vaccine according to schedule the experience was far better. Two other men acquired the infection; the remaining 6 have escaped despite a considerable number of recognized contaminations with strains of maximal virulence, of which 3 could be properly described as massive.

The two additional laboratory infec-

tions displayed such marked evidences of protection that they deserve detailed description.

I. W. G. was vaccinated in 1939 before working with virulent cultures in aerated liquid media. During the next year he worked with other materials and was not vaccinated. He resumed work with *B. tularensis* in 1941, and was given six 0.25 ml. injections of vaccine. Three months later he crushed a glass bulb culture tube in his right hand, a piece of glass penetrating the palm to a depth of about $\frac{1}{8}$ inch. The bulb was half filled with a 48 hour culture of a strain which killed all mice at 10^{-8} , and 60 per cent of mice at 10^{-9} dilutions, respectively. The wound was washed with soap and water. Immediately after the injury he received 0.10 ml. of vaccine into the right arm. On the following day he received 0.25 ml. into the left arm.

After an incubation period of 4 days he experienced a few chilly sensations, headache, aching of all joints of the right arm, and persistent interscapular backache. A very small reddened papule appeared at the site of injury; no lymphangitis or lymphadenitis. For the first 3 days he ached, felt "rocky," occasionally slightly chilly, and had low grade fever; no chills or sweats. He continued to work, complaining of occasional pain in the right axilla where no masses could be felt. Late in the 3rd day the nodule at the inoculation site measured 1 cm. in diameter, with a 3 mm. necrosing central area, the overlying skin yet unbroken. One node, 4 mm. in diameter, was felt in the right axilla. After painting with tincture of iodine the central necrotic area was carefully aspirated with a small needle. The material obtained was cultured, and a portion triturated in salt solution and injected into a guinea pig. After 3 days the cultures showed six colonies of *B. tularensis*; nothing else. The guinea pig died in 96 hours and showed

the typical gross lesions of rodent tularemia. Pure cultures of *B. tularensis* were obtained from its heart blood at autopsy.

The 5th day of disease was spent at home, due to fatigue and a mental "grogginess" which prevented clear thinking. He returned to work the next day, working almost two-thirds full time for 7 days. Thereafter he worked full time. Despite the needling the primary lesion did not ulcerate or further enlarge. Final healing, with slight scar, occurred on the 26th day. Four days after its appearance the enlarged axillary node measured $2 \times 1.5 \times 1.0$ cm. Four days later it was less than 0.5 cm. in all diameters. It receded gradually without re-enlargement, and became impalpable on the 26th day. Low grade fever, averaging 100°F. , persisted for 10 days. After that he was completely afebrile. On the 23rd day after initial symptom he developed a crop of typical erythema nodosum lesions, from just above the knees to the ankles, which persisted for 8 days. The maximal serum agglutinin titer was 1:1,280, on the 26th day after initial symptom. Beginning a month later he had two afebrile, symptomatic relapses, about 12 days apart. Each lasted for 1 day. The symptoms were fatigue, heavy sensation in the head, marked malaise, and slight arthralgias. Four additional recrudescences, each of only a few hours' duration, occurred about a week apart during the next month. For the past 6 months he has remained well.

In October, 1941, W. H. H. was inoculating large animals with saline suspensions of living strains of 10^{-9} virulence for mice and guinea pigs. While injecting a goat with 3 ml. of a T-2,000 suspension of a 48 hour culture (about 8 billion bacteria per ml.) the needle was forced off the syringe tip, back-firing the entire contents into the face of the operator. Some liquid was felt to enter each eye; the re-

mainder streamed down over the mouth, neck, and chest. Within 15 minutes the face was washed with soap and water, a drop of 20 per cent argyrol was instilled into each eye, and 0.10 ml. of vaccine was injected into each arm. Three days later a third dose of 0.05 ml. of vaccine was given.

This man had been vaccinated once or twice annually for 7 years, the last injection 6 months prior to the accidental exposure.

Since past experience had shown that antiseptic or germicidal collyria possessed little value, ambulatory treatment consisted of thorough flushing of the conjunctival sacs with boric-saline solution five times during the first 2 days. No other treatment was administered.

On the second day after exposure both lower lids, and the right upper lid, were erythematous and edematous. In each conjunctival sac there were many minute oval, gelatinous, elevated areas of localized edema on erythematous bases. None showed erosion of the surface. There appeared one small red papule on the right cheek. There were no constitutional symptoms, fever, or regional lymph node enlargements. Smears of the conjunctival fluid showed a few small bacilli consistent in size and staining with *B. tularensis*. A guinea pig was injected with material swabbed from both lids of the right eye. This animal remained well.

On the 5th day a single yellow-gray nodule appeared in the mucosa of the right lower lid, surrounded by a red, velvety, inflammatory area. The focus of necrosis measured 3 mm. It was larger on the next day. Each morning the lids were stuck together with exudate. They were still thickened and discolored. The papular cheek lesion disappeared.

The solitary primary lesion enlarged during a period of 3 days, after which it receded rapidly, and disappeared on

the 9th day after exposure. At this time the entire area was normal in all respects. There was complete absence of fever, regional adenitis, and all constitutional symptoms. Work was continued energetically throughout the entire period.

Although the organism was not recovered by animal inoculation the serum agglutinin titer of the man rose from 1:80 4 months prior to the accident to 1:640 at 3 months after the local infection. Apparently vaccine had induced such a high degree of resistance that a massive contamination of both eyes resulted only in a solitary abortive primary lesion in one eye, possibly another on the cheek, without regional lymphatic extension and without the production of constitutional symptoms. The sequence of events, save for the site involved, was identical with some of the local reinfections seen in recovered immunes and described by Francis.¹

All laboratory infections reported hitherto have presented the typhoidal clinical type of disease. The last two of the three cases reported here differ in that one was ulceroglandular and the other ocular.

The complete freedom from infection of three of us with a total of 23 exposure years, and the extraordinary degree of favorable modification of disease in the above two cases, are scarcely conceivable for tularemia as results due to any cause other than protection conferred by vaccination. This laboratory experience supports our opinion that a considerable part of the apparent freedom from infection and amelioration and shortening of the disease among members of the experimental group, were due to vaccination.

DISCUSSION

We would have preferred a standard type of vaccine, but under the stated circumstances and limiting conditions,

the oxidized vaccine was the only one found suitable for mass trials. The relatively low serum agglutinin titers indicate an antigenicity lower than that desired. We are unable to explain the observation that revaccination provoked titers which averaged lower and showed a lower extreme range than those induced by initial vaccination. Since revaccinated persons were better protected it is inferred that agglutinin titers bear little relation to the degree of protection. Decrease in antigenicity of vaccine due to oxidation was demonstrated by measuring agglutinin titers in rabbit sera after equivalent amounts of formalinized, heat killed, and oxidized suspensions were injected intravenously. Simultaneous injections and bleedings resulted in the titers shown in Table 7.

ous stages of recovery from disease invariably resulted in failure, when mice and highly virulent cultures were used, we did not try to measure protective antibody in sera from vaccinated persons. In controlled studies on the highly susceptible rabbit Downs demonstrated that formalinized vaccine induced a high degree of resistance and considerable protection against infective doses fatal to unvaccinated animals.⁵ The survival periods of her control rabbits indicate challenge strains of less than maximal virulence. Unpublished experiments from several laboratories, including ours, are in agreement that vaccine prophylaxis of laboratory rodents consistently fails to protect against a challenge m.l.d. of any strain of maximal virulence. Under these

TABLE 7

Serum dilutions		1:10	20	40	80	160	320	640	1,280	2,560
Made by	Formalinized	4	4	4	4	4	4	4	4	3
	Heat killed	4	4	4	4	4	4	4	4	2
	Oxidized	4	4	4	4	4	4	2	0	0

Rabbit serum agglutinins produced by equivalent amounts of the three antigens. All titers were measured with standard formalinized antigen.

The agglutinability of oxidized bacteria was not altered, since sera from many animals always agglutinated such suspensions to titers found for formalinized suspensions. Furthermore, equivalent agglutinin absorption was demonstrated for oxidized and formalinized bacteria in equal amounts. Oxidation impairs antigenicity without altering the surface antigenic components which unite with antibody *in vitro*, indicating that surface components are not major factors in producing protection.

Living avirulent vaccines have not been tried.

Since many efforts by ourselves and by others to demonstrate protective antibody in sera from patients at vari-

conditions vaccinated animals occasionally die sooner than normal ones. We have not been able to protect rabbits with oxidized vaccine, regardless of the interval between vaccination and infection, if a strain of maximal virulence was used for the challenge dose.

With this infection it is likewise impossible to demonstrate passive protection by hyperimmune animal sera in laboratory rodents against infecting strains of maximal virulence. Our long unpublished experience is in complete agreement with that recorded by others.⁶ The administration of serum from a long and heavily vaccinated uninfected person to a patient in the acute stage of tularemia resulted in a prompt and persisting lowering of temperature,

amelioration of symptoms, and reduction in size of buboes, but the serum had no protective value for guinea pigs. Rodents are unsuitable animals for either purpose. Many difficulties encountered in immunologic studies on experimental tularemia in rodents closely resemble those observed in experimental plague. In the absence of a suitable test host we are at present forced to rely upon results of studies on man for evidences of vaccine protection and of potency of therapeutic antisera.

Since the duration of protection probably seldom exceeds 1 year for the majority of those vaccinated, and is apparently less for the remainder, revaccination is advised at least annually when exposure is seasonal. If exposure is anticipated throughout a considerable part of the year, as in laboratory work, wild life investigations, or a military establishment in our western states where fly-borne or tick-borne disease commonly occurs throughout the summer, revaccination with small doses is advisable every 3 or 4 months during the period of exposure.

We appreciate that this study is incomplete, that the experimental group is small, and the observation period short. Our original plan to continue work until a large number of vaccinated individuals could be followed for many years, with extension and expansion of related laboratory studies, has had to be modified. Various factors associated with our entry into war have already operated to disperse the group, to alter exposure risks, and to modify otherwise conditions of study. The promising results obtained, and the possibility that vaccination might be advisable for men concentrated in certain regions during the war,

prompt us to report a summary at the present time.

SUMMARY

The experience with 2,145 exposed, susceptible persons indicated that a useful degree of protection was conferred by annual vaccination.

More frequent vaccination of exposed laboratory personnel gave more convincing evidence of a high degree of protection.

The vaccine had certain stated disadvantages partly outweighed by the following practical advantages: ease and safety of subcutaneous administration without provocation of severe reactions or of sterile abscesses, short administration period, and reliable reproducibility on small scale production.

Individuals who were not completely protected experienced significant favorable modifications in the course of disease.

The Relation of Childhood Infection to the Development of Tuberculosis in Early Adult Life

HAROLD L. ISRAEL, M.D., M.P.H., AND
HORACE DELIEN, M.D.

*Henry Phipps Institute, University of Pennsylvania, Philadelphia, Pa.; and the
Office of Indian Affairs, U. S. Department of the Interior, Washington, D. C.*

IT is well known that the mortality from pulmonary tuberculosis is extremely low between the ages of 5 and 14 years. The great majority of tuberculous infections and lesions acquired during childhood retrogress without treatment, and reinfection-type pulmonary tuberculosis is rarely seen, even though a considerable portion of tuberculous children are presumably exposed to reinfection. The appearance of reinfection-type pulmonary infiltrations becomes more frequent in adolescence; it is probable that this change in the character of the tuberculous process is determined in large measure by age-linked factors.¹

The belief that the seemingly benign infections of childhood are responsible for much of the morbidity and mortality from tuberculosis which occur in adult life is still widely held, as evidenced in recent publications.²⁻⁷ Direct evidence for this belief is, however, meager. A number of studies have been reported in which the frequency of tuberculosis has been compared in persons who had had a positive tuberculin reaction and persons showing a negative reaction during childhood. Such studies show a higher incidence of tuberculosis in the group infected during childhood. The inference that the higher morbidity is the result of the childhood infection would

be valid, however, only in so far as the risk of infection in adult life is equal in the two groups. Thus, individuals remaining tuberculin-negative cannot be considered to have undergone a risk of developing tuberculosis. The assumption that subsequent exposure to sputum-positive tuberculosis is equally common among persons having household contact during childhood and those without childhood contact is demonstrably incorrect. In the present study, children having household contact with sputum-positive tuberculosis were five times more likely to have similar intimate contact during adult life than infected children not in household contact. In the case of tuberculin-negative children, there is a presumption that they reside in households free of tuberculosis and in areas where casual infection is uncommon, and where it is therefore relatively unlikely that they will have household contact in adult life. Whether the morbidity among persons who had been infected in childhood is the result of initial or subsequent exposure can be determined only if accurate information is available concerning the presence of household contact during adult life as well as in childhood. Such information has been obtained in families under supervision of the Henry Phipps Institute. The present report is a considera-

tion of the influence of household contact during adult life upon persons who had been infected during childhood; such an analysis should demonstrate the relative importance in the pathogenesis of adult tuberculosis of the initial infection occurring in childhood and subsequent exogenous infection resulting from household exposure during adult life.

MATERIAL AND METHOD OF STUDY

The records have been studied of families whose supervision at the Henry Phipps Institute began between 1924 and 1932. A detailed description of the medical and nursing supervision given these families has been made by Opie and McPhedran.⁸ It is worthy of emphasis that home visiting by staff nurses has been equally intensive and persistent in families with sputum-positive tuberculosis, families with sputum-negative tuberculosis, and a control group of families free of tuberculosis. In no instance has family care been voluntarily discontinued; observation has been maintained except when families moved, leaving no trace. A recent interview with members of these families was obtained in a remarkably high proportion of cases. Recent roentgenological examination was obtained in a large percentage of the individuals observed but, in order to obtain results comparable to other studies of this type, the present report deals with the incidence of clinically manifest tuberculosis rather than with the incidence of roentgenologically demonstrable lesions.

The limit between childhood and adolescence has been arbitrarily placed between the ages of 13 and 14 years; it has been required for inclusion in the present series that the person before the age of 14 years have acquired naturally a positive reaction to 0.01 or 1.0 mg. of Old Tuberculin and have had a chest roentgenogram which was either negative or revealed primary-type lesions

only. Among the children fulfilling these requirements there were 982 concerning whose health status in adolescence and adult life information was available. The duration of observation after the age of 13 years extended from 1 to 17 years. The total number of person-years of observation during adolescence and adult life was 7,530. The mean duration of observation after childhood was 7.9 years for white males, 8.0 years for white females, 6.2 years for colored males, and 6.8 years for colored females.

Three white and 3 colored patients who had developed clinically manifest reinfection-type tuberculosis before the age of 14 years have been excluded, since the purpose of the present study is to determine the fate of infected persons who are apparently healthy upon entering adolescence. For the same reason, it has appeared desirable to exclude also persons who had asymptomatic reinfection-type infiltrations prior to the age of 14 years. This exclusion is practicable, since in the case of the 36 persons included in the study who developed manifest tuberculosis in adult life, it was demonstrable in all but 2 instances that reinfection-type disease was not present at the age of 13. The likelihood that these 2 persons had asymptomatic infiltrations during childhood is small. It should be emphasized that, although asymptomatic reinfection-type infiltrations appearing in childhood account for only a relatively insignificant portion of adult morbidity from tuberculosis, such lesions have serious clinical consequences as brought out by Sweany.⁹ Six white girls, 1 white boy, and 3 colored girls were observed to have asymptomatic reinfection-type lesions between the ages of 11 and 13 years, and 8 of these individuals developed clinically manifest tuberculosis in adolescence. Inclusion in this study of persons having reinfection-type disease during childhood would result in a

somewhat higher morbidity rate for the group as a whole. The other findings reported are not substantially altered, however, as shown by a test analysis including these cases.

In recording the presence within the household of persons with positive sputum or of fatal cases of tuberculosis with history of cough and expectoration, the records have been compiled on an individual basis; that is, one member of a family born in 1920 and exposed to a sputum-positive grandfather dying in 1923 is recorded as having been in contact, while another member of the family born in 1925 is included in the group not exposed to positive sputum. The group of families in which sputum-positive contact was not present include families whose tuberculous members had sputum-negative (in large part asymptomatic) pulmonary disease or extrapulmonary tuberculosis, as well as families in which no member had tuberculosis. These groups have been combined for the purposes of the present study, since only slight differences in incidence of tuberculosis during adolescence and adult life were noted among members of these various groups.

Because of the importance of the age factor, the morbidity during adolescence and adult life has been calculated on an age-specific basis. The number of individuals under observation at each age was obtained by counting each person as many years as he was years under observation after the age of 13. Thus a person followed from the age of 6 to 18 is included in the totals for ages 14, 15, 16, 17, and 18.

The social and economic changes occurring in these families during the long period of observation are of interest. Dramatic changes in financial status were infrequent. Despite the economic depression of the last decade, there appeared to be improvement in the circumstances of a considerable portion of the families. In another large group of

families, however, in part presumably as the result of chronic illness in the household, the social and economic status deteriorated.

MORBIDITY AND MORTALITY DURING ADOLESCENCE AND EARLY ADULT LIFE— INFLUENCE OF AGE, COLOR AND SEX

Among the 982 persons observed, clinically manifest tuberculosis developed in 36 (Figure 1). These included among white males, 5 cases of pulmonary tuberculosis and 1 case of tuberculous cervical adenitis; among white females, 13 cases of pulmonary tuberculosis and 1 case of pleurisy with effusion; among colored males, 2 cases of pulmonary tuberculosis and 1 case of tuberculous osteitis; among colored females, 8 cases of pulmonary tuberculosis, 2 cases of pleurisy with effusion, 1 case of tuberculous osteitis, and 1 case of tuberculous meningitis. The disease was fatal in 14 instances.

Although the morbidity rate at various ages fluctuated considerably, Table 1 shows that the mean annual attack rate for the ages 14 to 21 years closely approximated the rate for the ages of 22 to 30 years, both in the white and colored groups. It is therefore permissible in subsequent calculations to consider that the risk of developing tuberculosis is the same in a year of observation at the age of 24 as in a year of observation at the age of 14. The cause of the static morbidity rate noted in this study will be discussed later under "Comment."

The annual morbidity rate was three to four times greater among Negroes (1.21 per cent) than among whites (0.33 per cent).

The morbidity among females at the ages studied was considerably higher than among males. The rate in white females (0.44 per cent) was twice that of white males (0.21 per cent), and the rate in colored females (1.69 per cent) was three times that of colored males

(0.54 per cent). The morbidity among females was largely concentrated in the adolescent years, while that among males was concentrated in the later years. A high morbidity in early adolescence was particularly marked among colored females. These sex differences in incidence, which are in accord with

familiar observations on the general population, appeared to be independent of the time of occurrence of household contact with sputum-positive tuberculosis, and may properly be considered to be governed by constitutional factors.

Although the number of deaths was small, the rates paralleled those of

similar groups in the general population; i.e., the mortality was many times higher in Negroes than in whites, and was higher in young adult females than in young males. In each group the rate was roughly twice the rate expected in persons of corresponding age in the general population of Philadelphia (Table 2).

**INFLUENCE OF HOUSEHOLD CONTACT
WITH SPUTUM-POSITIVE TUBERCULOSIS**

It is evident from the data presented in Table 3 and Figure 2 that a markedly higher morbidity occurred among persons intimately exposed to sputum-positive tuberculosis during adolescence than in those with no record of household exposure. The rate was equally

* Including children who had had prior contact

† Omitting reduplications resulting from inclusion of persons exposed in adult life in the groups without adult contact, prior to the onset of adult exposure

low among white persons not having household contact during adolescence, whether or not they had been exposed during childhood. A higher rate was observed among colored persons who had childhood contact than in those without a record of household contact; this was particularly notable in the case of persons last having contact in the later years of childhood, and is presumably correlated with the marked susceptibility of colored females in the early years of adolescence.

The differences in morbidity between persons having household contact during adult life and persons not having such contact are, on application of the chi-square test, significant in the case of the colored group and highly significant in the case of the white group.

Worthy of note also is the correlation between household contact during childhood, the prevalence of primary-type tuberculosis, and the occurrence of household contact in adult life. Household contact during childhood was noted in 418 white children; of these 83 (19.8

per cent) had continuance or recurrence of household contact in later life. Among 355 white children who did not have childhood contact, there were 10 (2.8 per cent) who had household contact in adolescence or adult life. Similarly, of 118 colored children having household contact, 19 (16.1 per cent) had similar contact in adult life; and among 91 colored persons not having contact during childhood, 7 (7.7 per cent) had household contact with sputum-positive tuberculosis in later life. It is evident that tuberculosis is more truly a "household disease" among whites than among Negroes.

Among the 418 white persons having household contact with sputum-positive tuberculosis during childhood, 165 (39.5 per cent) had roentgenological evidence of active or calcified primary-type pulmonary lesions, while such lesions were found in only 59 (16.6 per cent) of the 355 persons who did not have contact in childhood. The corresponding percentages among colored persons were 39.8 and 18.7.

RELATION TO ROENTGENOLOGICALLY
DEMONSTRABLE PRIMARY-TYPE
TUBERCULOSIS

Pope, Zacks and Sartwell¹⁰ found a significantly higher morbidity in persons with roentgenological evidence of calcified childhood-type tuberculosis. In the present study, a higher morbidity rate was observed in white persons with calcified lesions (0.48 per cent) than in those with negative films (0.26 per cent), but the morbidity rate was 0.96 per cent among colored persons with primary-type lesions and 1.32 per cent in those with negative films. That this difference between whites and Negroes is not fortuitous, but may be due to a group difference in epidemiological behavior, is suggested by the observation that calcified primary-type lesions are much more often seen in association with clinical tuberculosis among white adults than among colored adults.¹¹

The greater morbidity observed in white persons with calcified lesions may be due to the facts that calcified lesions occur more frequently in children having household exposure to sputum-positive tuberculosis and that persons having had household contact during childhood are more likely to do so subsequently. Calculation of mor-

bidity rates among both white and colored persons not having known household contact after the age of 13 years shows a slightly higher incidence among those having calcified lesions (Table 4). This difference may be the result of chance, as is suggested by the fact that the difference is not significant on statistical analysis, or it may actually represent a slightly greater risk resulting from endogenous breakdown.

EFFECT OF PREVENTORIUM CARE

Friedman and Billings¹² have reported a study of the incidence of clinically manifest reinfection-type tuberculosis among a group of persons followed after discharge from the Pendergast Preventorium. The 409 children studied had a mean age of 8 years on admission to the preventorium and a mean age of 21 years at the end of the follow-up period: the total number of person-years of observation may be calculated to be 5,318. In order to compare properly these data with those in the study of families at the Henry Phipps Institute, it is necessary to restrict the observation period to the interval after the age of 13 years. It may be calculated that 3,262 person-years of observation occurred after this

TABLE 4

Morbidity from Tuberculosis among Young Adults Who Had Been Tuberculin-positive During Childhood. Relation to Presence of Roentgenologically Demonstrable Primary-type Tuberculosis in Childhood (excluding person-years of observation after onset of household contact in adult life)

	Number of Persons	Person-years of Observation after Age of 13 (Prior to Adult Contact)	Number Developing Tuberculosis after Age of 13 Years	Attack Rate (per cent)
<i>White</i>

Active or healed primary- type lesion	62	369	4	1.11*

* Comparison of the number of cases observed in persons with negative films and the number expected on the basis of the morbidity rate in persons with primary-type lesions reveals that these differences are not statistically significant.

age. All 9 of the cases which developed appeared after the age of 13 years,¹³ giving a mean annual morbidity rate in adolescence of 0.28 per cent.

The number of children in the present study who received preventorium care was small. Twenty white children, or 2.6 per cent of the total, were in preventoria for intervals of more than 3 months. It is interesting, therefore, that the incidence of reinfection-type tuberculosis during adolescence in the entire group of white persons (0.33 per cent) is not appreciably greater than in the group of similar composition who had received care at the Prendergast Preventorium.

COMMENT

An annual morbidity from tuberculosis during adolescence and early adult life of 0.33 per cent and a mortality rate approximately twice that of the general population of Philadelphia may appear to be surprisingly low when it is considered that the population studied had been infected during childhood, was an indigent or semi-indigent one, living in a congested urban area, observed in large part during a period of severe economic depression, and further handicapped in a majority of instances by the presence of wage earners or other adults ill with the chronic disease of tuberculosis. Possibly the cause of this low rate lies in the relatively small number of persons who had recurrence of household contact with sputum-positive tuberculosis after childhood. It is an interesting question to what extent these findings represent the natural history of the disease under present-day conditions, or to what extent they have been influenced by the therapeutic and educational efforts made by the clinic physicians and public health nurses. Thus the fact that the same morbidity was observed in persons having preventorium care and in those not having such treatment, may be construed as indicating

that preventorium care has no effect on the morbidity in adult life or, on the other hand, may be interpreted as indicating that the educational efforts of a clinic of the type of the Henry Phipps Institute are as effective as preventorium treatment in reducing the morbidity from tuberculosis in later life. It should be recognized as a limitation of this type of epidemiological study that the mere fact that a family is urged to have examinations may alter its subsequent behavior and may lessen the spread of disease.

The mean annual morbidity observed in this study is, as has been pointed out, practically identical with the rate (0.28 per cent) which prevailed during adolescence in tuberculin-positive persons discharged from the Prendergast Preventorium.¹² A similar annual morbidity rate, ranging from 0.2 per cent at the age of 14 years to 0.4 per cent at the age of 18 years, was observed in the large series of observations on tuberculin-positive Massachusetts school children reported by Pope, Sartwell and Zacks.¹⁰ It should be pointed out that the rates found in these three investigations are not comparable to the rate reported by Ch'iu, Myers, and Stewart,³ for in the latter study a significant proportion of the morbidity and mortality observed occurred during childhood. Disease and deaths occurring before the age of 14 years have been excluded from the present study, which is concerned rather with the likelihood of subsequent development of tuberculosis in individuals who, previously infected, enter adolescence in apparent good health.

In neither of the Massachusetts studies was consideration given to the influence of household contact during adolescence. In the families studied at the Henry Phipps Institute it has been possible to obtain accurate information concerning the presence or absence of sputum-positive tuberculosis. Analysis

on the basis of this information indicates that the annual morbidity rate of approximately 0.3 per cent found in these studies represents a composite of a low rate occurring among those not exposed during adolescence and a high rate occurring among those having onset, continuance, or recurrence of household contact during adolescence. The extremely low rate observed in white persons not exposed to household contact in adult life is especially remarkable in view of the high risk of casual infection in the district of Philadelphia served by the Henry Phipps Institute. It seems reasonable to believe that the previous tuberculous infection afforded an increased resistance sufficient to protect against casual infection, although it is evident that this protective effect was obliterated when household contact with sputum-positive tuberculosis was present.

It is noteworthy that no rise in morbidity with increasing age was noted in the present study, in contradistinction to the generally recognized fact that the incidence of tuberculosis rises throughout adolescence and early adult life. This rise is considerably more rapid than the increment of infection during this period of life and must be considered the result in large part of age-linked alterations in resistance. The diminution in resistance during early adult life is masked in the present study by the fact that only persons infected during childhood have been included. In the general population, on the other hand, there is a constant accession of persons infected for the first time at the ages of 14, 15, 16, etc., and it is reasonable to assume that these newly infected persons account for a portion of the morbidity from tuberculosis in the latter years of adolescence and in adult life. In the general population, moreover, while the percentage of children having household contact is far smaller than in the group under study,

there is no such marked decline in occurrence of household contact during adult life as has been observed in the present study. Thus, in the general population, the likelihood of household exposure at the age of 20 years is less than at the age of 12 years only to the degree that the prevalence of open tuberculosis in the community has declined in the 8 year interval. The present study is comprised largely of members of tuberculous families: 54.6 per cent had contact with sputum-positive tuberculosis in childhood while only 12.1 per cent had contact in adolescence, reflecting the frequent termination of exposure either by death or as the result of treatment. It should be emphasized that although household contact in adult life was much more frequent among the members of families under study than it is in the general population, nevertheless it is true that the risk of household exposure for the group under study declined sharply in early adult life, while in the general population the risk declines only slightly. As a result of the sharp decline in occurrence of household contact in the group under study the excess of morbidity over the general population was great in early adolescence, and smaller in subsequent years, the net result being a static rate. In the general population, on the other hand, the almost constant risk of infection during adolescence to persons previously tuberculin-positive as well as tuberculin-negative, associated with a decline in resistance during these years, results in an ascending incidence of tuberculosis.

Pulmonary tuberculosis developing during adolescence and early adult life in persons who had not had household contact after childhood, may be endogenous, i.e., due to progression of the original infection, or exogenous, i.e., the result of fresh infection acquired outside the household. That both possibilities may occur² cannot be doubted,

but it is a question which is the more frequent. A striking example of the fact that not all tuberculosis developing in the absence of known household contact can be considered endogenous is afforded by the case of J. G., an Italian male. He was first examined in 1928 at the age of 13 years because of the diagnosis of asymptomatic minimal tuberculosis in his father. The tuberculin reaction was 2+ to 0.1 mg. OT, and x-ray examination of the chest was negative. In 1929 the tuberculin reaction was 1+ to 0.1 mg. OT, in 1932 the reaction was 3+ to 1.0 mg., and in 1933 there was no reaction to 1.0 mg. In January, 1935, there was no reaction to 0.005 mg. Purified Protein Derivative and x-ray examination of the chest remained negative. In March, 1936, at the age of 21 years, respiratory symptoms developed. The tuberculin reaction was 2+ to 0.00002 mg. PPD and x-ray examination showed moderately advanced tuberculosis. The sputum was positive.

Despite treatment, the patient died 18 months later. No other member of the household had sputum-positive tuberculosis, although a number of siblings developed or re-developed tuberculin sensitivity in 1937 and one became ill with pleurisy with effusion.

That similar reversion of the tuberculin reaction from positive to negative is not uncommonly observed when the tuberculin test is frequently repeated, has been shown by Dahlstrom.¹⁴

It has been pointed out¹⁵ that in many of the studies demonstrating a higher incidence of tuberculosis in members of families containing a sputum-positive patient, the multiple family incidence might be due not to greater opportunity for infection but to a hereditary deficiency of resistance. The demonstration in the present study that the more recent the contact the greater the morbidity, suggests that multiple family incidence is due more

to the factor of infection than to genotypic factors.

The data reported in the present study give no information as to the relative risk of morbidity in adult life of persons infected in childhood and those uninfected. That a somewhat greater morbidity under equal conditions of exposure occurs among adults who are previously uninfected is demonstrated by most studies of student nurses and medical students,¹⁶ and patients in mental hospitals.^{17, 18} It is clear, on the other hand, that under the ordinary circumstances of life, infected and non-infected children do not undergo the same risk of exposure in adult life. No simple statement, therefore, can describe the risk of tuberculosis experienced by persons infected in childhood. A comprehensive statement must include the following considerations:

1. Morbidity and mortality from tuberculosis before adolescence, high in infancy, and very low during the remaining years of childhood, are by no means negligible, and of course occur only among those infected during childhood.

2. The survivors, i.e., those who enter adolescence with calcified lesions or without roentgenologically demonstrable lesions, exhibit under similar conditions of exposure a somewhat greater resistance than those previously uninfected.

3. On the other hand, persons having household exposure or having otherwise been infected during childhood undergo a certain risk of endogenous breakdown, and are under ordinary circumstances more likely to have exposure to infection during adolescence and adult life.

4. The greatest risk of tuberculosis in adolescence and adult life is experienced by those having recent household contact with sputum-positive tuberculosis, whether or not they were infected during childhood.

The person infected during childhood thus is at greater risk even though partially protected. He is better able to withstand casual infections; yet the very fact of having been infected in childhood carries with it a greater likelihood of encountering in adult life

household contact with sputum-positive tuberculosis. And against this intimate exposure, the increased resistance conferred by previous infection does not afford protection.

SUMMARY

1. Observation during adolescence and early adult life was given 982 individuals who had had a positive tuberculin reaction during childhood. Accurate information concerning the occurrence of household contact with sputum-positive tuberculosis was available.

2. The mean annual morbidity rate was 0.33 per cent in the white group, and 1.21 per cent in the colored group.

3. The mean annual morbidity rate was 0.21 per cent in white males as compared to 0.44 per cent in white females, and 0.54 per cent in colored males as compared to 1.69 per cent in colored females.

4. The mean annual morbidity rate was 0.1 per cent in white persons not having household contact after childhood as compared to 2.0 per cent in white persons having household exposure during adolescence and adult life; the corresponding rates for the colored group were 0.98 per cent and 3.62 per cent.

5. The morbidity rate in persons who had roentgenological evidence of primary-type tuberculosis was not, in the absence of household contact in adult life, significantly higher than the rate in persons with negative films.

6. The rate of 0.33 per cent observed in white persons, relatively few of whom had had preventorium care, was not appreciably higher than the rate calculated from comparable data reported in persons discharged from preventoria.

CONCLUSIONS

1. Morbidity from tuberculosis in adolescence and early adult life is more frequently the result of household exposure after childhood than before, indicating that in early adult life exogenous infection is of greater importance than endogenous breakdown of lesions acquired in childhood.

2. Case finding efforts in adolescence and early adult life should be directed toward persons having recent household contact with sputum-positive tuberculosis. Prolonged supervision of persons exposed during childhood is not indicated unless household exposure is continued or recurs in adult life.

Public Health and Medical Relationships in Industrial Health*

ORLEN J. JOHNSON, M.D.

Council on Industrial Health, American Medical Association, Chicago, Ill.

THE immediate necessity of this war is production of great amounts of military supplies. In fact, the length and outcome of this conflict are dependent on the rapidity with which our united armies can be equipped with tanks, airplanes, guns, munitions, and other accouterment, and transported to every continent of the world. We have seen the effectiveness of coördinated utilization of all types of mechanization in warfare. Just as they have been coördinated, so must the forces of production be coördinated. In a general sense production rests on only two factors—man power and materials. Even the flow of materials is dependent on man power. There the simplicity of the matter stops, consideration of man power is complex.

Its capacity to produce is affected by a multiplicity of influences—not the least of which is its physical well-being or health—as individuals and as a group. The importance of the health of the worker is not generally comprehended, despite the seemingly great amount of emphasis which has been placed on it.

All those working or actively interested in health have the grave responsibility of bringing about such changes as will result in maximum utilization of man power.

The early development of medicine

or health work was directed toward curing the sick individual. With the discovery of the specific cause of some diseases, immunization or prevention became effective. When employers were made financially responsible for injuries to workmen, prevention of accidents and occupational diseases became the wisest course. The results were material and easily visualized. But preventive industrial procedures in their broad application apparently do not lie within the conception of many industrialists and health workers. It is preventive industrial health that is so vital today. The term industrial health means all phases of industrial medical services — environmental sanitation, treatment of injuries, and, most important of all, prevention. Treatment of the sick or injured individual is of receding importance in this enlarging field. The incapacitated worker is to be restored as soon as possible, but more significant is keeping the well worker on the job and instituting measures which will improve those below par in order that they will not lose time.

War is impersonal, subjugating humanitarian interests to a secondary rôle. Though it is not entirely desirable to consider industrial health in the same manner, it can be done. Without doubt, it is the type of treatment of the subject most readily grasped. It has been stated that in 1941 there were 400 million man days lost in industry from physical disability—that this lost man power was sufficient to build 20,000

* Read before the Western Branch, American Public Health Association, at the Thirteenth Annual Meeting in Seattle, Wash., May 28, 1942.

bombers or a line of tanks 250 miles long.

Considering it from the dollars and cents angle—the loss to the wage earners alone at an arbitrary average wage of \$5 per day was 2 billion dollars.

The loss to the employer is greater. One authority¹ has stated that the direct loss from non-occupational illness due to disturbances of production is one and one-half times the wage of the absent employee. This means the direct loss to industry was 3 billion dollars. Figures issued by one manufacturer² reveal that a 50 per cent reduction of absenteeism would save them \$70 per worker. Thus a proper preventive medical program would save about 3½ billion dollars in the country as a whole. Yet the United States Treasury Department estimates the net profit of industry in 1941 was 8 billion dollars.

Obviously, if medical groups and management continue on the old plan of treatment only, there will be no reduction of this loss. Rather, the trend so far is upward. In one state, the accident frequency has increased over 100 per cent in the last year. The tension, longer hours of work, and rising costs of living are among the factors which have caused a 10 per cent increase in absenteeism in defense plants. If this condition is not rectified and the upward trend of accidents and illnesses continues—as it surely will as production becomes more intensified—not only will the economic loss increase, but it will be a greater handicap to the production of materials we so sorely need.

Management has learned to include these losses in the cost of production, which is reflected in the price of the product. Unfortunately, the wage earner is unable to make such an adjustment during sickness and the compensation he receives from occupational

injury is a poor substitute for good health and a full pay envelope. As a result, a vicious cycle is established—sickness stops his income, which lowers this family's standard of living. This not only lowers his efficiency as a worker but is manifested in the well-being of the entire family. It is axiomatic that the economic state has a direct bearing on general health.

The implication is obvious—preventive procedures if properly carried out will help improve the whole social structure.

It would seem that a program of such potential merit would progress rapidly. Unfortunately, interest in industrial health has only just begun and in a desultory manner up until the inception of the defense program. The attitude toward it now is the same as existed toward vaccination, immunization, and sanitation in earlier days. It is an attitude resulting from incomprehension of the meaning and value of preventive procedures in industrial health. No group, professional or otherwise, is entirely blameless. In relation to industry—the practising medical profession thinks in terms of traumatic surgery; nurses consider it in the light of first aid; except for industrial hygiene personnel, health departments think only of sanitation or cross-connections; managements' conception is that of accidents and insurance premiums; and labor—the real beneficiary—greet it with resistance or a feeling of persecution.

For many years there have been a few proponents of the preventive aspects of industrial health, but latterly with the realization of its proper position, new forces have been added to its development, and its scope is being defined. It has suddenly attained the dignity of a specialty.

In recognition of its reciprocal importance to the future of the medical profession, the Council on Industrial

Health of the American Medical Association was organized late in 1937. It has set down and promulgated the objectives and procedures of industrial health as a whole. An "Outline of Procedure for Physicians in Industry" was published by the Council in the *Journal of the American Medical Association*, March 14, 1942. It embodies the general principles and functions of industrial medical service. It states that—

... the purpose of medicine in industry is to promote the health and physical well-being of industrial employees, these objectives to be accomplished by:

1. Prevention of disease or injury in industry by establishing proper medical supervision over industrial materials, processes, environment, and workers.

2. Health conservation of workers through physical supervision and education.

3. Medical and surgical care to restore health and earning capacity as promptly as possible following industrial accident or disease.

There is nothing new in these statements, but they represent something which both physician and employer can catch hold of. Heretofore, it has been believed that these principles apply only to large institutions. Even so, many have not incorporated them. More important, the numerically superior small plants can and should have an equally complete program of industrial medical service. "The quality of medical service in industry should be uniform—the quantity only varying with the size of the plant." The first argument presented against such a thesis is economic—small industry cannot afford to enter into such a plan. There has not been enough evidence, by surveys or otherwise, to substantiate the belief that this type of service properly carried out is economically unsound. In the large plant a full-time physician performs examinations, treats injuries, and perhaps supervises plant hygiene and carries out health educa-

tion. New experiences are demonstrating that the cost should not be much greater if the required amount of service—commensurate with the size of the plant—is secured on an hourly basis from a private physician.

THE PHYSICIAN

Ideally, industrial health requires putting into operation in every plant adequate medical supervision, satisfactory to those who receive and those who supply the service. The real obstacle to this type of service for small plants—and the most difficult to overcome—is the lack of recognition by industry and the medical profession of the efficacy of preventive procedures. This does not imply that all large plants have an adequate medical service—quite the contrary. Many that would be justified by any standard in having a full-time medical service have only a physician on call in event of accidents, or one who comes into the plant for an hour or so and confines his attention to wrapping fingers or otherwise treating injuries. Ability to extend preventive services in these plants depends upon the vision and improved training for all physicians. The physician will not hesitate to relinquish the old for the new practices if their real significance is brought forcefully to his attention.

Returning again to the small plants—those too small to warrant full-time medical service. Those with less than 500 workers comprise over 90 per cent of the industrial establishments. It was stated that all of them could and should have an adequate service. The important thing is an appreciation on the part of the physician of the importance of prevention. He must realize also the relationship of working conditions and the health of the workmen. He need not be a trained industrial hygienist but he should know what, if any, operations or exposures may be present in the plant which may cause illness and what the

signs of such illness may be. To apply this knowledge he must be intimately aware of the physical details of the industry and the requirements of each process therein. In turn this knowledge enters into the decision as to the type of work a man is able to perform. It is fundamental to preemployment and periodic physical examinations, which are just as essential whether dealing with 100 men or 1,000. The physician who serves industry must be neutral, being neither unduly prone to ascribe to working environment conditions not readily accounted for, nor failing to recognize the evidence of occupational influence. It is an understanding of industrial etiology.

All studies to date indicate that industrial conditions cause only 10 per cent of the time lost from work because of physical disability, the remaining 90 per cent resulting from illness affecting the general population. Consequently the greatest loss to the worker, industry, and society as a whole is from this source. There are certain known facts having a bearing in this matter.

It was stated earlier that a manufacturer could save \$70 per employee by a 50 per cent reduction in absenteeism. Now it has been found in numerous plants that 12 to 15 per cent of the employees cause 55 to 60 per cent of the time lost by sickness.³ In other words, this small group are sickness prone and should be the choice for concerted attention along prevention lines. If their record could be made to approach that of the remaining more healthy group it would be a notable achievement. And that is exactly what has been done in some plants. A study of their records indicated that some needed specific remedial work, and that all could be improved by general measures. By a plan of education, dwelling on nutrition and health measures and adjustments in relation to working requirements and shifts, the incidence of absenteeism in

this heretofore sickness prone group was reduced to the general level. Not only that—it was found that the entire plant population benefited and a considerable amount was carried into the homes by the workers.

INDUSTRIAL MEDICAL SERVICE

There are plans by which the small plant may organize a medical service. The physician in practice may call at the plant at stated hours and perform as much of his work as possible. This affords him the opportunity of becoming familiar to the employees and the conditions under which they work. Health lectures, first aid instruction, physical examinations, supervision of plant hygiene, and health consultation are duties he can carry out.

Another plan is the formation of a unit or group capable of rendering a similar service to a number of small plants. This has been carried out in modifications fairly successfully.

In Springfield, Vt., a working arrangement has been established whereby the physicians of the community spend time in two plants by rotation. It is a co-operative plan between management and the local profession. Apparently it is mutually satisfactory. It is reported that some of the doctors are so fascinated by the work that they spend considerably more than the stipulated time in the plant.

The important part of all these methods is that work is done in the plant. Probably no one method will serve the purpose of all areas, yet there are practical methods in operation. It behooves the medical profession to solve this matter. The time will come when management will rightfully expect that any physician worthy of caring for the injuries incident to the operation of a plant will have knowledge of and render preventive service. It will be a recognized responsibility. It has been found advisable to have one supervisor or

foreman to about every 10 workers—why should not comparable consideration be given to his health.

NURSING

Nursing is an important component of industrial medical service. Full-time nursing service is not only advisable but essential in all but the smallest plants. Its scope has broadened with the development of preventive procedures. No longer is the nurse's attention confined to first aid treatment. She is expected to take an active part in health education and within the limitations of her ability become interested in the correlation of the employee's physical condition and the influence of his surroundings while at work. And in this broadening lies the crux of the matter of developing preventive industrial nursing.

There are many nurses working in industry without background or training in prevention or health education. They have been carrying on well, within the limits of their understanding. Recently they have been confronted quite precipitantly with a movement which implies that for years they have been remiss in their duties as industrial nurses and that only those with public health training are capable of working in this new field.

This large group of nurses with years of experience in industrial relations should not be set aside but encouraged to broaden their activities to include this preventive phase of nursing. This may be done in the meetings of local nursing associations or clubs or by formal postgraduate courses offered now by a few schools. Unfortunately reports on these courses do not show a very high enrollment.

Part-time nursing service for small industries is receiving considerable attention in several areas throughout the country. There is a similarity in all the plans in operation in that the service is

offered on an hourly basis and that the duties of the nurse during these visits include health consultation, first aid, and supervision of conditions in the plant. It has been reported that the demands on her time usually increase. The organizations offering this service are usually staffed by public health nurses who may or may not have formal training or experience in industrial health.

The report of the American Public Health Association's Committee to Study the Duties of Nurses in Industry should reveal the proper plan for nursing service in small industries. It is certain that, to be of assistance in developing industrial health as a whole, any plan should be coördinated with all other phases under medical supervision.

HEALTH OFFICERS

There is one valuable group which has not universally taken up the cudgels for industrial health—health officers, including state commissioners. Notable contributions have come from a few. Unquestionably more would come if their interest could be focused in this direction. The task of technical service and industrial health promotion is too great in most states for the personnel allotted to bureaus of industrial hygiene. The field of industry contains some 50 million individuals whose health has a direct bearing on all the phases in which health departments are working. There is no field more fertile for tuberculosis case finding, nutrition, and health education, venereal disease control, and study of adult illnesses. One of the features distinguishing private practice from health departments is that one studies the individual and the other groups. The health department thinks about the incidence of disease in a community as a whole. But here is this large assemblage of workers—collected under one roof so to speak—that has received practically no attention as

such from the specialists in group health—the health officers.

THE WORKER

In reality in considering industrial health, the workers come first. Individually and collectively they are the prime beneficiaries. In fact, any program which does not achieve this end is certain to fail in time, for if the worker does not gain better health one way or another, none of the good we claim will accrue. This is a fundamental principle of industrial health—yet it needs to be promulgated among all interested agencies, and particularly among wage earners. Many plans for health education in industry have been set forth. None to date has utilized the influence of workers' organizations.

Too frequently we encounter the attitude that the wage earner is opposed to health plans. In some instances this is true, but is usually due to a lack of understanding of the objectives, or an unsound plan. In no program properly conceived can this be considered an insurmountable obstacle. Some form of representation of the wage earner should be included in the planning and execution of every program of industrial health.

THE EMPLOYER

"The worker being the prime beneficiary—the employer is the number one consumer of industrial health." If the employer is not interested to the point of expanding his program, obviously there is no market. He is the one who puts programs into effect. The only areas which have made significant progress are those working intimately with a local industrial organization. The signal success of such a working arrangement in Connecticut is outstanding.

These groups, then, the workers, employers, nurses, the medical profession—industrial and practising physicians, health officers, and industrial hygien-

ists—are the main parts in the structure of industrial health, each fitting into its proper position. But as organizations each needs assistance in making effective its efforts in relation to all others. While it may appear that each phase is an entity, there is an actual multiple interlocking dependence which makes each unit or phase necessary to a properly integrated whole. It is recognized that there are other interested parties that may contribute materially, such as safety and personnel organizations, insurance companies, industrial commissions, rehabilitation agencies, and voluntary health agencies.

The extension of industrial health requires leadership at state and local levels to bring about concerted effort. Industrial health should center in the medical profession, and that includes every specialty—health officers and industrial hygienists not excepted. As matters have progressed, the Council on Industrial Health has become more impressed with the responsibility placed upon the medical profession by the leadership in industrial health. The program outlined for both state and county committee activity consists of:

1. Organizing and carrying out a plan of activity
2. Educating the medical profession and industry in preventive measures as applied to the worker
3. Coördinating the efforts of all agencies

The Council has recommended that the membership of all coöperating state and local committees include representation from the local bureau of industrial hygiene or the health department. In the formative stage it was felt that their technical training and close association with industry would be of valuable assistance to such committees. This belief has been justified. Programs on industrial health have been enhanced wherever coördinated effort has been applied, particularly since the viewpoint has broadened from that of occupa-

tional disease control. This coöperative activity should not be confined to medical industrial hygienists. Plant management has learned to turn to the bureaus for advice in environmental control. This is an ideal opportunity for outlining a well rounded medical service and more industrial hygienists should capitalize on it.

At present industrial health is faced with an emergency which can only be met by the balanced development of a program. By fulfilling these requirements a structure will have been built which will assure the future of industrial health.

The indicated course of action to meet the war emergency and develop a long term program is—

1. Promulgation of the modern concept of industrial health among and by all interested agencies

2. Education of the personnel necessary to supply this service

3. Coördination of all activity in such a manner as will assure even development and mutual assistance

The responsibility of the medical profession and allied groups to apply modern industrial health measures supercedes all non-military demands on their ability. The recognition and discharging of this responsibility is the greatest contribution they can make toward the successful completion of this war.

Dissolved Air as a Source of Error in Fermentation Tube Results

J. ARCHAMBAULT, PH.D., AND M. H. MCCRADY, F.A.P.H.A.

Division of Laboratories, Ministry of Health, Montreal, Canada

IN the course of a comparative study of media for detecting the presence of coliform organisms in water, it was remarked that bubbles of gas were appearing with suspicious frequency in Durham fermentation tubes of an experimental medium which previously had yielded satisfactory results. The medium in the great majority of the tubes containing these gas bubbles was clear or only slightly turbid, and upon transfer from such tubes to eosin-methylene-blue agar, either no colonies, or atypical colonies that failed to ferment secondary lactose broth, developed on the plates.

A closer study of these abnormal results revealed that they first appeared after a slack, mid-winter holiday period of about 15 days. Since the tubes of medium then employed had been in the refrigerator more than 3 weeks, and since the gas bubbles formed upon incubation did not seem to be the result of bacterial fermentation of the contained lactose, it was suspected that these apparently false presumptives might be due to the liberation, upon incubation, of air that had been dissolved by the medium during the extended period of storage at the low temperature. This suspicion appeared the more justifiable because the experimental broth had been kept in the refrigerator to prevent excessive evaporation, whereas the other media, which had caused no difficulty, and the supplies of which are frequently renewed because of their constant use

in routine work, had been kept at the room temperature of the laboratory. Obviously, the conditions under which the experimental broth was stored were conducive to concentrations of dissolved air greater in the experimental broth than those to be expected in the other media.

Fortunately the validity of this explanation of the suspected false presumptives was susceptible of immediate proof, for a few tubes of the lot of experimental broth that had been employed still remained in the refrigerator. Upon overnight incubation of these tubes at 37° C., gas formation was observed in nearly two-thirds of them, the diameter of the bubbles in some being as large as 2 mm.

This interesting observation led to a study of the solubility of air in broths of various concentrations at different temperatures. Lactose broths, of one, two, and three times the usual concentration employed in water work were prepared, distributed in bottles of 5 cm. diameter, 100 ml. in each bottle, and autoclaved at 15 lbs. for 15 minutes. The dissolved oxygen in the contents of one bottle of each concentration was determined by the Winkler procedure* of Standard Methods immediately after sterilization and after 4, 7, 11, 16, 22,

*Although the routine Winkler method perhaps does not yield strictly correct results when applied to lactose broths containing various concentrations of organic matter, it was considered sufficiently precise for the purpose of this study.

and 42 days of storage in the refrigerator at approximately 4° C.

The dissolved oxygen contents of all the broths were found to increase, from very low figures immediately after sterilization, to maxima (saturation) in the 4 day samples, the results of subsequent tests remaining practically unchanged. The amounts of dissolved oxygen found were 9.2 mg. per liter in the single strength broth, 6.4 in the double strength broth, and 5.0 in the

triple strength broth. These figures express approximately the solubility of atmospheric oxygen in these broths at a temperature of about 4° C. Figure 1 shows graphically the same results in ml. per liter (0° C., 760 mm.); the curve has been completed by indicating also the volume of atmospheric oxygen that water alone, which may be considered as a broth of "zero concentration," can dissolve at the same temperature.

Figure 1

Solubility of atmospheric oxygen and of air in lactose broths of different concentrations at the temperature of 4° C.

Included in Figure 1 is a second curve, calculated from the oxygen figures on the assumption that the volume of dissolved oxygen is 34.74 per cent of the dissolved air at 4° C. (composition of air in water saturated at this temperature), showing the approximate volume of *air* that may be dissolved in these broths. This hypothetical curve indicates not only the effect of the concentration of the medium on the solubility of air, but also the appreciable volumes of air that broths of various concentrations may be expected to dissolve at the temperature of the refrigerator.

When considering the application of the above data to bacteriological laboratory practice, however, many factors must be taken into account. It is well known that the solubility of a gas in a liquid decreases with a rise in the temperature: broth kept at a low temperature will hold in solution a larger volume of air than will broth kept at a higher temperature. Consequently, the volume of air that may be liberated from a broth upon incubation depends upon the difference between the incubator temperature and the antecedent storage temperature. The possibility of the occurrence of the phenomenon known as supersaturation must also be considered.

Furthermore, the conditions in a fermentation tube are very different from those under which the experiments described above were conducted. Although the medium in the bottles employed rapidly became saturated with air when held at a low temperature, it is improbable that the medium contained in the vial of a Durham fermentation tube will become saturated so quickly. It is obvious that any air dissolved at the surface of the medium in the outside tube must, in order to reach the vial, be transported, by diffusion or by currents caused by differences in density due to dissolved air or to temper-

ature, first to the bottom of the tube and then into the vial. The transfer from the surface to the bottom of the outside tube may be effected rapidly; but the rate of passage of the air into the vial will depend upon the size of the opening between the rim of the latter and the bottom of the outer tube: if the opening is small, the air will pass very slowly, probably almost entirely by diffusion, from the tube to the vial. If, on the other hand, the opening is comparatively large (as when the rim of the vial is broken, or when the vial is in a slanting position), the rate of passage into the vial will evidently be greater.

In order approximately to determine the conditions of time and temperature required for dissolved air in fermentation tubes of broth to attain concentrations which result in liberation of visible gas when the tubes are incubated at 37° C., further experiments were made. Supplies of lactose broths of various compositions, distributed in tubes of different sizes and types, and autoclaved in the usual manner, were stored at certain temperatures. From time to time, a few of the tubes were taken at random from each lot and incubated at 37° C. After 24 hrs., and again after 48 hrs., they were examined and any gas formation was recorded. The results obtained are summarized in Table 1.

These results show very clearly that if fermentation tubes of the broths indicated are held for an extended period at a low temperature, the air dissolved may cause, upon incubation at 37° C., the formation of gas bubbles in the vial of the Durham tubes or in the closed arm of the Smith tube. Bubbles were observed in a large proportion of the incubated tubes, both in lactose broth held at 4° C. and in the experimental broth held at 13° C. None of the tubes, however, that were stored in two locations, the temperatures of which varied from 16° to 24° C. and from 24° to 27° C. respectively,

TABLE 1

Effect of Time and Temperature of Storage of Lactose Broths on Fermentation Tube Results When Subsequently Incubated at 37° C.

Type	Tubes Diam. in mm.	Volume of Broth	Media	Storage Temperature	Storage Period in Days	Results upon Incubation *	Storage Period in Days	Results upon Incubation *
Durham	25	20 ml.	Lactose broth 1½ times strength	4°	6-18	0/12	22-35	5/12 = 42%
					12	0/3	27-56	2/15 = 13%

					4°	0.1	9-27	9/9 = 100%

* Denominator = Number of tubes incubated
 Numerator = Number of tubes containing a bubble of air

showed gas formation upon incubation, even after storage periods of 35 to 71 days.

The minimum holding period that resulted in liberation of visible gas in the fermentation tubes of broths of normal concentration upon incubation at 37° C. was 7 to 10 days, with the exception of one lot in which no bubbles appeared before 15 days of storage.

An increase in the concentration of broth, at least when Durham tubes are employed, apparently lengthens the period of storage required for production of visible gas upon incubation. In tubes of broth of 1½ times the normal concentration no bubbles appeared upon incubation until the storage period was extended to 22-27 days.

It is interesting to note, in the last column of Table 1, that the proportions of tubes with visible gas vary greatly,

even when media of the same composition and concentration, and stored at the same temperature, are employed. This variation is due to several causes: different storage periods, different initial contents of dissolved air after sterilization, and different sizes and positions of openings between the rim of the vial and the bottom of the outer tube of Durham fermentation tubes, and between the open and closed arm of Smith tubes. The results obtained from Smith tubes deserve particular mention: evidently because of the large opening between the open and closed arm, gas bubbles appeared upon incubation of practically all of these tubes after a storage period of only 9 days at 4° C.; moreover, as might be expected because of the comparatively large volume of liquid contained in the closed arm of these tubes of the usual

type employed in water examination, the bubbles of gas produced therein were of considerable size.

Since the solubility of air in water at 37.5°C . is only about 13.8 ml. (0°C ., 760 mm.) per liter, whereas that at 4°C . is 26.32 ml., it is evident that if the solubility of air in a broth were the same as the solubility in water, the liquid contained in the vial of a Durham tube or the closed arm of a Smith tube, when saturated with air at 4°C ., might release upon incubation a volume of the gas equal to more than 1 per cent of its capacity. Although the solubility of air in a given broth is not exactly that in water, but varies with the composition of the broth, the results of the experiments described establish beyond doubt the important fact that the solubilities of air in various broths are such that visible gas may be released when these broths, after previous storage for several days at a low temperature, are subjected to incubation at 37°C .

The practical importance of the possible effects of storage at comparatively low temperatures of fermentation tubes which, subsequently, are to be incubated at higher temperatures, is self-evident. Bubbles of air resulting simply from a change in temperature may deceive the laboratory worker into believing the gas thus formed to be the result of bacterial fermentation. Not only in the bacteriological examination of water, milk, etc., but also in the differentiation of species of bacteria by means of tests for gas production in sugar media, the possibility of this source of error must be guarded against.

Consequently, in order to prevent the occurrence of false fermentation tube results, there must be added to the usual precaution of avoiding the conversion, by the heat of sterilization, of the fermentable constituents of the medium employed, that of preventing such concentrations of dissolved air in the

medium that visible gas will be released upon incubation. To this end fermentation tubes should be stored at temperatures not far below that of 25°C ., and be used after only a limited period of storage. If storage of such tubes at lower temperatures for longer periods is unavoidable, however, they should be incubated overnight, and carefully inspected, and those observed to contain air bubbles discarded before use.

SUMMARY

The results of experiments with lactose broths of various compositions contained in fermentation tubes have shown that, when such tubes are stored for a sufficient time at a low temperature, a large proportion of them may contain dissolved air in such concentration as to produce, upon incubation at 37°C ., visible bubbles of gas.

Seven days of storage of single strength lactose broth at 4°C ., or even at 13°C ., sufficed for the production, upon incubation at 37°C ., of visible gas in some of the fermentation tubes.

The frequency with which gas bubbles may thus be produced depends upon several factors: (a) the initial concentration of dissolved air in the broth immediately after sterilization; (b) the concentration of the ingredients of the broth; (c) the size and position of the opening between the vial and tube of the Durham tube or between the open and closed arm in the Smith tube; (d) the difference between the temperature of storage and that of final incubation; and (e) the duration of the storage period.

In order to avoid errors in fermentation tube results due to dissolved air, the tubes should preferably be stored at temperatures approximating 25°C . and, since evaporation may proceed rapidly at such temperatures, they should be used after only a limited period of storage.

THE AMERICAN PUBLIC HEALTH ASSOCIATION MEETING THIS MONTH

IT is very nearly an unwritten law that in the fall of each year the Editor of the JOURNAL beat with vigor the bushes of Association membership, to the end that the old dogs and the cats and the bears, and the dears and the foxes and the rabbits and the rats of public health all go lumbering, or hopping or scurrying, as befits their station, to the Annual Meeting of the Association. And aside from bushes-beating, certain bait, differing from time to time, is set out: the increase in knowledge that comes from such attendance; the broadening of acquaintanceship; the celebrities to be seen and, inevitably, heard; the meeting of old friends; the coming together of North, South, East, and West, Canada, Mexico, Central and South America. Sometimes even, in this attendance-getting effort, guarded reference is made to the sociability to be found, if one knows where to look for it, when austerity goes out the window and back hair comes down. These benefits and pleasures are parts of any annual meeting of any association, where people with common interests gather: serious, scientific and orderly sessions, plus a decent after-hours gaiety.

For the meeting to be held in St. Louis the latter part of this month we beat no bushes, we set no bait. Nor have we any desire to give a light touch to the soberness of the occasion. The mere fact that the meeting is to be held, in spite of war conditions, is testimonial to its seriousness of purpose and to its necessity. Some five to ten years ago, when routinism was pretty deeply rutted, it probably would not have mattered much if an annual Association meeting had been cancelled, unless that particular meeting would have pulled things out of the rut. Today the situation is on the one hand encouragingly different and on the other distressingly so. Public health workers are faced, as never before, with many new and many more problems. Shifting of populations, concentration of troops and war industries, depletion of the ranks of practising physicians, losses of personnel on public health staffs—all these things have changed the tempo and confused the situation. There is another problem, too, that needs attention. It is this: No longer is it sensible or practicable to regard the public health activities or the stand-

ards under which they are performed, the recruiting and training of personnel, or the problems of finance as being entirely prerogatives and obligations of the locality in which this health department or that operates. In all the nations of the world today, and probably for a long time to come, life and living must be in terms of national economy and national effort. To function on such a basis, public health work must be retooled, for although coördination between federal, state, and local health agencies has in the past been rivaled only by similar coöperative effort in agriculture, and has far surpassed that of other governmental bureaus, direct public health service is still geared essentially to the existing pattern of state and local governments. Serious thought, therefore, needs to be given to those adjustments which, without destroying the basic structure of state and local responsibility, will permit and assure national influence and assistance in meeting problems wider than state boundaries.

These things are to be discussed at the meeting this month. Only through contributions from all the far reaches of this country and this hemisphere can a wise course be plotted.

TO A FEW GOVERNORS AND MANY POLITICIANS

GOVERNOR, why in Heaven's name can't you keep your hands off your department of health? Surely, in calling a physician to treat a member of your family, you would not be guided by the advice of a political campaign manager, nor would you be influenced by the fact that one doctor is a Democrat and another a Republican. If your child had pneumonia or were otherwise seriously ill, you would not wait to find out how this physician or that had voted in the last election or how much he is likely to contribute to the next campaign fund. And, having a family physician, you would not, certainly, change to a less competent one merely because you found that he had been unwilling to perform some political chore for your good friend Senator Soandso. No, one who has sense enough to attain leadership in political affairs doesn't engage or dismiss a private physician as a matter of political expediency, because the danger of disaster is too close home. But have you ever thought, Governor, of the responsibility you assume in the hiring and firing of the state health officer and other personnel in the health department of the state for whose health and well-being you bear the ultimate responsibility? It is not a matter to be taken lightly, nor is it one that can be settled by paying a political debt.

Illnesses and deaths which occur because of unwise decisions and acts on your part, sir, are, of course, way out on the fringes of things, too far off and too intangibly related to your affairs ever to be recorded on the debit side of your record. Nevertheless, these catastrophes exist as grim effects of definite causes. An incompetent worker here, a political-minded appointee there, through ignorance or dereliction of duty or even by sheer laziness, may set in play a chain of events that will as surely result in disaster as would a fumbling surgeon in the operating room. Or the untrained health officer, for want of knowledge as to the conduct of a modern health program, may, by omission, permit unnecessary sickness and funerals. An incompetent laboratory worker may fail to discover the danger in a water sample or may read incorrectly the picture under the microscope, or misinterpret the story told in a test tube. These things, sir, are not dramatic, are seldom discoverable, and sometimes will occur in spite of every precaution.

But, Governor, is it not your responsibility, your opportunity, to appoint to positions in your health department only those persons in whom sins of omission and commission are least likely? And who are these persons? The answer is not difficult. They are those who by training and experience in public health work and by personal integrity have demonstrated professional competence, sound judgment, and trustworthiness. Many of them are already in your department of health. They are faithful, diligent workers, jogging along on low salaries, never at political rallies, unknown to your organization, asking only to be permitted to do their jobs. *Governor, please, in all decency, leave such people alone!* Sometimes, the person you will need for a particular job may live a thousand miles away. If he does, sir, will you bear in mind the fact that competence and incompetence are not determined by state boundaries. If in your own state you cannot find the right person, don't pull the work down to the level of whatever or whoever is available among registered voters.

The protection of the public health is a serious job, and a hard enough one at best. At present, many of the most competent workers must be yielded for military duty, because they are young and robust, and the Army and the Navy need them. At this time, then, above all, don't throw your political weight about in the health department. If there are incompetents on the job—and no one can deny that there are some—they must be rooted out. But in discharging such persons, first get a good state health officer, or *keep the one you have if he is competent*, and let him make the decisions on the basis of their records and in accordance with the merit system which it is to be hoped you have provided or will adopt.

We ask this, Governor, not so much for those who might have lost or might lose their health department jobs for political reasons. Though such unfair treatment is hard on them as individuals, their plight is relatively unimportant. But we do ask for competent public health workers for the sake of the people who look to you for wisdom and protection. Further, Governor, if you are one of those inclined to regard health department jobs as part of a patronage pool, please be advised that years ago this went out of fashion, even in the realm of political expediency. It is generally regarded as poor politics, lacking in finesse, and likely to be resented by the better element among your constituents, particularly by the women. The latter can raise the devil of a row about that sort of thing, and they don't care what they say, or to whom or when or where they say it. And, finally, sir, those governors who play politics in health departments constitute only a rapidly dwindling minority. If you do this and keep it up you are going to find yourself alone, unhonored and unsung, maybe un-officed.

P.S. Your personal physician is not likely to make a good state health officer.

BOOKS AND REPORTS

Health Education of the Public— By W. W. Bauer, B.S., M.D., and Thomas G. Hull, Ph.D. Foreword by Morris Fishbein, M.D. (2d ed.) Philadelphia: Saunders, 1942. 315 pp. Price, \$2.75.

The preparation of a useful handbook for health education is a large task; a revision is far from simple, requiring initiative and perspective. The second edition of this instructive and practical volume reveals imagination and judgment in the selection of illustrations and an insight into the needs of both the field worker and the instructor in the clear presentation of subject matter.

In bringing their well known book up-to-date, the authors, well equipped for the task, added new chapters on a Philosophy of Health Education and on Training and Qualifications, besides featuring a study of words habitually used by doctors in writing for the public. Chapters on health meetings, motion pictures, exhibits, radio, and the newspaper have been revised; chapters on stereopticon slides and on correspondence contain many helpful suggestions; a discussion of measurement of results should promote further study in this important phase of the subject. Anyone engaged in community health education, whether as administrator, specialist, student, or teacher, will find valuable assistance and stimulus in this new edition.

IRA V. HISCOCK

Essentials of Nursing—By Helen Young. New York: Putnam, 1942. 609 pp. Price, \$3.00.

This book is written by a group of authors who worked together in teaching nursing arts in the School of Nursing which is connected with the Pres-

byterian Hospital in New York City. The school was founded fifty years ago by Anna C. Maxwell, and this volume is prepared as a tribute to her. It will also be a memorial, for all the royalties are to be devoted to the scholarship fund of the Alumni Association.

There is significance in the fact that the central theme of *Essentials of Nursing* is the patient. All through the book emphasis is placed on contact with the patient, and the reaction of the patient to treatment is given importance.

While written for teachers of nursing arts and their students, the book will be of equal or greater value to the graduate nurse as a reference book. The illustrations are numerous and excellent, and technics are in sequence and logically described.

The material on nursing patients for communicable diseases is particularly well done as is that on nursing patients on whom a tracheotomy has been performed.

All procedures in surgical nursing are especially well described. Obstetrical nursing and charting, perhaps by contrast, appear to have been somewhat neglected.

For the student nurse it would have been desirable to have given more attention to principles underlying procedures, but for the graduate it is entirely adequate.

ELNORA E. THOMSON

A Handbook for Assistant Medical Officers of Health on Child Welfare and School Medical Work—By F. J. G. Lishman, M.D. London: H. K. Lewis & Co., Ltd., 1942. 61 pp. Price, \$1.50.

This handbook was prepared to guide junior medical officers who

were added to the staff of the Devon County Council, England, as a result of the migration in 1939-1941. It will give American public health officials a brief but satisfactory account of procedures in the Maternity and Child Welfare Centres and School Medical Services in England. The Welfare Centre is described as primarily educational. Ten minute talks to mothers by the Medical Officers are mentioned, and printed instructions are recommended to be issued singly at appropriate intervals.

The School Medical Service is given the major attention and shows the tendency in England as in this country to use the observations of teachers and principals to select children in need of medical attention. There is, however, more emphasis on routine examinations than is recommended by the latest American viewpoint. Twelve examinations per hour including parent conferences, is described as normal practice, but a rate of six per hour is mentioned as "necessary for adequate discussion of the child's health with the parent." School clinics for treatment of "minor ailments" are described as more efficient than referring children to the family doctors. "Curiously enough," says the author, "children suffering from otorrhoea are also considered to have a minor ailment."

Procedures and records are outlined sufficiently to indicate the routines of practice but they do not make clear the educational possibilities of the services. The Appendices containing "model leaflets" for parents are an interesting feature indicating some advice not altogether consistent with our best American practice. HAROLD H. MITCHELL

The American Pocket Medical Dictionary—By W. A. Newman Dorland. (17th ed.) Philadelphia: Saunders, 1942. 1037 pp. Price, \$2.00; thumb indexed, \$2.50.

A compact and well edited dictionary, with definitions usually clear and to the point. In the communicable disease field the information is reasonably up-to-date, though transition from the old bacterial nomenclature is incomplete. Considering the inherent difficulty in such condensation, it is well done. REGINALD M. ATWATER

Sex Guidance in Family Life Education: A Handbook for the Schools—By Frances Bruce Strain. New York: Macmillan, 1942. 340 pp. Price, \$2.25.

Mrs. Strain has made an outstanding contribution to a field that has been full of confusion for well over forty years. The need of getting away from the disastrous Victorian silences was met by enthusiastic converts who plumped over backward for detailed biological lectures to young children. Now that parents are rather generally ready to use the help of the school, the educators must be able to furnish realistic answers to the questions that start out with irreconcilables. This book is addressed directly to school people, who have been acquiring a sense of obligation regarding "sex education" but without being able to discharge it in terms of curriculum, content and methods, and other school categories. Here they are told *how*. Some of the main topics treated are: Gaining Community Support, Matters of Organization, Needs at Various Age Levels, Personal and Academic Qualifications of Teachers, and Counseling Center.

Mrs. Strain's book presents a sound philosophy regarding the functions of schools and homes in the child's education, and clarifies the issues which underlie most of the confusion. As one of the few persons who have been able to try out the possibilities of the school, she can speak to teachers in their own language. The book is full of concrete suggestions as to procedures, without

being dogmatic as to "subject matter," and without descending to the fallacy of offering "techniques of instruction." Indeed, one of the valuable features of this treatment is its help in clarifying for teachers the possibility of guiding educational procedures through a dynamic understanding of young people and children, rather than formal rules of teaching. This will be a valuable aid in orienting schools toward children as members of families and as prospective founders of families.

SIDONIE MATSNER GRUENBERG

Prostitution and the War (Public Affairs Pamphlet No. 65)—By Philip S. Broughton. New York: Public Affairs Committee, 1942. 32 pp. Price, \$.10.

This excellent publication issued by the Public Affairs Committee of New York presents the problem of prostitution from a public health point of view rather than dealing with the moral aspects of the problem. The age old question of segregation and examination of prostitutes as a means for the control of venereal diseases is directly handled. No shadow of a doubt should remain in the reader's mind as to the incompatibility of this procedure with the reduction of the incidence of venereal diseases.

The amount of exposure which is experienced by a prostitute in an open house of prostitution is clearly shown. The average prostitute has from 25 to 40 sex exposures in her working day and this may be increased to as many as 60 to 65 on busy days. Such a woman obviously acts as a mechanical vector of syphilis and gonorrhea and is not necessarily afflicted with the disease which she spreads. Such conditions are not compatible with medical examination. The mere closing of open houses of prostitution lowers the venereal disease rate of a community because the number of sex exposures of

a prostitute operating as a street walker rather than in an open house of prostitution is reduced from 25 to 40 exposures to from 2 to 4 exposures in each working day.

The material is presented in very logically arranged form explaining the responsibility and function of the various official agencies from a national and local level, the problem of prostitution, the social responsibility of the community, and the national need for local action. Specific local experiences with problems under discussion are offered to strengthen the various points presented.

This important publication should be read by every law enforcement officer in the country and it should prove to be of great assistance to venereal disease control officers and venereal disease control public health nurses in selling repression of prostitution to their local communities.

J. C. GEIGER AND RICHARD A. KOCH

American Foundations and Their Fields—Compiled by Geneva Seybold. New York (330 W. 42nd Street): Raymond Rich. Associates, 1942. 274 pp.

Once again Medicine and Public Health head the list of purposes for which grants were made in 1940 to various fields by 134 American Foundations.

A total of 12¼ millions went to these purposes in the latest year of record, amounting to 30.4 per cent of all the grants by foundations. Education, Social Welfare, the Physical and Biological Sciences, and the Social Sciences follow Medicine and Public Health in that order. Grants to religious purposes now stand at 3 per cent of the total, whereas fifty years ago these topped the list.

This volume, the fifth in the series, is again prepared by Raymond Rich Associates of New York and is much

the most comprehensive review available. The activities of 314 foundations, with total capital funds in excess of one billion dollars, are included. Even this is not all the so-called "foundations."

A wealth of information is available regarding these agencies, their fields, their officers and directors, and the expenditures of their funds. A highly recommended volume.

REGINALD M. ATWATER

The Fundamental Principles of Mathematical Statistics: With special reference to the requirements of Actuaries and Vital Statisticians—By Hugh H. Wolfenden. New York: Macmillan Company of Canada, for the Actuarial Society of America, 1942. 379 pp. 35 diagrams. Price, \$5.00.

This book attempts to assemble and coördinate those portions of the theory and applications of mathematical statistics which are needed by actuarial beginners and by qualified actuaries. Essentially it is an exposition of the subject of probability in the classical manner, with emphasis on the theory of errors and least squares. The arrangement of the material is novel in that the main text is a condensed presentation largely devoid of mathematical proofs and applications. These aspects are reserved for separate sections of the book, one on *History*, a second on *Mathematics and Interpretations* containing proofs, and a third on *Applications*, particularly to actuarial data. The Bibliography of 367 references is divided into two parts to denote historically important and currently useful publications.

The exclusion from the main text of the treatment of history, mathematical proofs, and applications inevitably leads to a degree of discontinuity. The reader interested in all aspects of a given topic must refer continually from section to section. This reviewer feels that the bird's-eye view of statistics

given in the main text is inadequate for an elementary student without considerable mathematical attainment and that a mathematically versed student would prefer to have the later sections appropriately inserted.

The usual ideas on probability are presented, leading up to the point binomial and its approximation by ordinates and areas of the normal curve. The use of the modulus of the normal curve instead of the standard deviation will seem awkward to many readers. The various types of sampling of attributes, as Bernoulli, Poisson, Lexis, and their relation to the chi-square test of heterogeneity are discussed. The sampling theory of means and standard deviations for large and small samples are adequately treated, but it is unfortunate that the distinction between the theory appropriate for the sampling of attributes and that of measurements is not more sharply drawn.

There is the usual treatment of systems of frequency curves, including those resulting from scale transformation. The author also discusses curves of particular interest to the actuary, as the life table functions, mortality laws, laws of population growth.

The author takes up in some detail topics considered only briefly or not at all in many treatises on mathematical statistics. These include a demonstration of the standard errors of functions of a variable, in some cases by the use of a Taylor's Series. Thus he evolves the standard errors of the life table functions. Consideration is also given to the multinomial law and its relation to the normal surface and to chi-square. There is an excellent discussion and comparison of various methods of curve fitting and graduation, as maximum likelihood, least squares, moments, minimum chi-square, together with criteria for testing goodness of fit. Another unusual feature is the presentation of the method of fitting transcen-

dental trends by the use of Taylor Series.

Some of the more recent advances in mathematical statistics, as confidence limits, testing of hypotheses, analysis of variance, are mentioned only briefly.

This book should be an exceedingly useful reference manual to the vital statistician, since many of his special tools are given more adequate treatment here than in most works on mathematical statistics.

JOHN W. FERTIG

Handbook of Hygiene—By Joseph W. Bigger. (2d ed.) Baltimore: Williams & Wilkins, 1941. 414 pp. Price, \$4.50.

This book, intended primarily for medical students, contains 404 pages of text and 10 pages of index. It is well arranged, the material is presented in a clear-cut and concise manner and with a commendable directness. It reflects the points of view prevailing in Great Britain and, in general, the illustrative data are drawn from abroad. For American readers this is not disadvantageous as it tends to broaden the horizon.

However, the abbreviations on pages 64 and 65 for biologic agents used in immunizations are meaningless to most American readers. Apparently, American and British experience is not parallel as to the frequency of positive Mantoux tests among adults. Because of the imperfections in the system of compulsory vaccination in Great Britain, and the admitted dangers involved in the measure, the author questions whether vaccination might better be restricted to actual exposures in a country where the disease is not endemic. This assumes the existence of an alert, efficient, and integrated system of local health services, which we do not have in the United States. Even if but half of a population has a relative immunity to the disease, this constitutes a barrier of no mean value.

In view of the serious problems created by acute types of encephalitis in the United States, our medical students will find the chapter limited to encephalitis lethargica particularly inappropriate.

Concerning pulmonary tuberculosis the author states (page 82) "From the point of view of prevention, it is sufficient to know that the bacilli enter the body with inspired air contaminated either by droplets or dust." One is permitted to doubt that this statement as it stands is adequate.

In the chapter on disposal of wastes, the scant mention of the problem of back-siphonage leaves the reader completely uninformed as to the importance of this subject.

These and other points which might be mentioned do not detract from the value of the book as a whole. For its intended purposes, it must be rated as among the best of its type.

M. E. BARNES

Stedman's Practical Medical Dictionary—Edited by Stanley Thomas Garber, B.S., M.D. (15th ed.) Baltimore: Williams & Wilkins, 1942. 1,257 pp. Price, \$7.00; with thumb index, \$7.50.

One cannot review this volume as one would an ordinary text, for the excellence of a medical dictionary depends upon how well the editor has met standards of which the average professional worker is quite ignorant. Obviously there are complex etymological requirements, precedents, and usages that must be observed in such a task, and the lexicographer too must make many difficult decisions not covered by rules. It is not easy to attempt order and consistency and at the same time hold inviolate the terminologies arising from separate, independent, highly authoritative sources: the Pharmacopea, the Basle Anatomical Nomenclature, Zoölogical, Botanical, Bacteriological,

and Chemical Nomenclature, to say nothing of those dealing with Nosology.

Stedman's has always been one of the better medical dictionaries, and in the fifteenth edition Dr. Garber, the present editor, seems to have met these various problems expeditiously and completely. The new type is pleasing to the eye and, by appropriate contrast in boldness and size, guides one quickly to major headings, sub-headings and interpolations. With a publication date of June, 1942, the contents are inclusive and fresh.

H. S. MUSTARD

War Gases—By Morris B. Jacobs, Ph.D. New York: Interscience Publishers, 1942. 180 pp. Price, \$3.00.

With the threat of an attack on our shores growing daily, the problem of defense against chemical warfare agents becomes an important one. The publication of this concise reference handbook on the war gases is therefore very timely.

The problem of war gases is approached from the point of view of the analytical chemist. The physical and chemical properties of the war gases are concisely and completely presented. The analytical procedures are arranged after the fashion of laboratory handbooks and are easily accessible. The book is of limited use to those concerned with the medical aspects of chemical warfare, since it contains little or nothing concerning the pharmacological or pathological aspects of chemical warfare agents.

The reviewer, who is not an analytical chemist, has been informed by qualified individuals that the material is accurate and that all modern available information has been carefully and accurately recorded, although lack of adequate documentation makes it difficult to locate the source material.

This book fills a need in the chemical warfare field and should be useful to all non-medical gas officers (state gas con-

sultants and senior gas officers) concerned with civilian defense.

DAVID D. RUTSTEIN

Housing for Health—Papers presented under the auspices of the Committee on the Hygiene of Housing of the American Public Health Association, 1941. Available from A.P.H.A. Book Service. 221 pp. Price, paper, \$1.00.

The discussion of the criteria for the adequate housing of people has been the concern of investigators in this field for well over a century. During all this time the health aspects of the problem have taken a prominent position. The public health administrator, the physiologist, the social worker, the economist, and the lay citizens have all struggled with the problem in the hope of eventually developing standards of application which would be acceptable to the public at large and which would be within the realm of orthodox economic acceptance.

It has only been within recent years, however, that the public health profession has in an increasing degree made it its business to analyze the issues involved in a methodical and scientific manner, characteristic of its approach to other problems. When the Committee on the Hygiene of Housing of the American Public Health Association was created a few years ago, it set about the task of literally shedding light upon the details of housing necessity and housing requirements. Through these recent years a number of valuable studies and resulting papers have appeared under the general direction of the committee.

The volume now under review represents a collection of these documents published for the committee by the Milbank Memorial Fund as a further evidence of the Fund's continuing interest in the hygienic aspects of housing. The volume contains some 15 papers and reports, adding to the hitherto rela-

tively meager quantitative or engineering aspects of hygienic housing.

Important as this addition to knowledge is, the volume goes far beyond this contribution and provides an interpretation of the basic principles of hygienic housing. It relates its principles to municipal codes and their enforcement, to the technics of surveys and appraisals, and to the general problems of planning for recreation and decent family life.

One cannot read the volume without recognizing promptly that the issues involved in housing will far exceed the equipment, experience and perspective of the individual specialist in any field. The problem is one of joint integration of the technical and social activities of the physician, the engineer, the city planner, the law maker, the housing official, the mayor, and the interested lay citizen.

The collection of papers comes at an opportune time when the public health profession needs so much to be oriented with respect to modern housing. The volume, therefore, provides an excellent source for instruction, not only to the specialist in housing, but particularly to the practitioners in public health work to whom the public looks for guidance in matters related to housing.

It is interesting to point out, furthermore, Professor Winslow's comment in the volume that more damage is done to the health of the child of the United States by a sense of chronic inferiority due to the consciousness of life in sub-standard dwellings than by all the de-

fective plumbing which these dwellings may contain.

ABEL WOLMAN

Anoxia: Its Effect on the Body—
By Edward J. Van Liere. Chicago: University Press, 1942. 262 pp. Price, \$3.00.

This timely volume attempts to summarize the available information on the effects of lack of oxygen on the body. Many of the tables and figures have appeared in other monographs. The various organ systems are treated in a systematic manner, but no mention is made of the effects of altitude on the reproductive function. Although certain studies concerning the anemic, stagnant, and histotoxic forms of anoxia are cited, most of the data deal with the effects of decreasing the oxygen tension in the inspired air. The general reader will welcome the sections on the definition of terms and the classification of anoxia. The author's distinction between asphyxia and anoxia is commendable. Many investigators will not accept the interpretation that the erythrocyte changes which occur when man is subjected to anoxia are the result of splenic contraction. The chapters on acclimatization and the effects of anoxia on the central nervous system are interesting. The chapter concerning the effects of anoxia on the alimentary tract reviews Dr. Van Liere's work on the relation of oxygen lack to the function of this system. The reviewer regrets that the titles of the individual references are not given.

WALTER S. ROOT

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Two Hundred and Nine Needless Deaths—There is a tendency for diphtheria to become relatively more prevalent among higher age groups as the protective program for infants and preschool children continues. This finding concludes the annual compilation of diphtheria deaths during a year with no extensive outbreaks, but in which the decline, though actual, was far less impressive than in preceding years.

ANON. Diphtheria Mortality in the Large Cities of the United States in 1941. *J.A.M.A.* 119, 18:1503 (Aug. 29), 1942.

Typhoid Continues Its Decline—New England, the Middle Atlantic, and North Central states have maintained their enviable record of low typhoid fever rates. Noteworthy too are the significant decreases in the cities of the South Central states, in this annual compilation of reported typhoid fever deaths.

ANON. Typhoid in the Large Cities of the United States in 1941. *J.A.M.A.* 119, 15:1188 (Aug. 8), 1942.

When Old Folks Must Carry On—Attempts to improve the health of the aged through education are especially timely, for as fewer physicians are left to care for the civil population, there will be less and less medical attention available for the aged ill. Longevity, unless accompanied by health and ability to work may become a social evil, philosophizes this writer. To which we say: Amen.

DUCKLES, D. Nutrition in Geriatrics. *J. Am. Dietet. A.* 18, 8:508 (Aug.), 1942.

Facts vs. Enthusiasms—There is no evidence that any vitamin or hormone has any direct relationship to arthritis. Where a specific deficiency coexists, vitamins or hormones may help the patient, but not cure the arthritis. Ordinarily, articles on medical treatment are excluded from this bibliography, but this paper seems to be of public health significance.

FREYBERG, R. H. Treatment of Arthritis with Vitamin and Endocrine Preparations. *J.A.M.A.* 119, 15:1164 (Aug. 8), 1942.

Real Progress After a Hundred Years of Study—Just where we stand in the matter of polio research, prevention, and care is told in the fewest possible words, and clearly too, in this paper read before the annual meeting of the Canadian Public Health Association.

GUDAKUNST, D. W. Poliomyelitis: Control and Treatment. *Canad. Pub. Health J.* 33, 8:365 (Aug.), 1942.

Credits and Debits in National Nutrition—Failure in peacetime to meet the needs that were then known to exist resulted in impaired man power for the defense of the country in time of war. If we are to profit by past failures, we can make the children of our war generation better able to put the world together again. How this can be done is the nub of this discussion.

HESELTINE, M. M. Nutrition—Today and Tomorrow. *Pub. Health Nurs.* 34, 8:428 (Aug.), 1942.

More about Nutritional Shortcomings—At one hospital, one-fourth

of all patients had been on a deficient diet, and of these 11.4 per cent showed definite signs of vitamin deficiency.

KRUPP, M. A. The Incidence of Nutritional and Vitamin Deficiency. *J.A.M.A.* 119, 18:1475 (Aug. 29), 1942.

Mental Health in the Sticks—Work of a mental hygiene unit, in the suburban sections of a county with exceptional social services, is described, and health departments in less favored counties are urged to go and do likewise.

LORT, G. M. Mental Health Services in Rural Areas. *Pub. Health Rep.* 57, 31:1115 (July 31), 1942.

Ability To Work—Some illuminating statistics about the distribution of industrial and non-occupational illnesses, and time losses by sex and age groupings, are appended to this discussion of industrial health. It is pointed out that two-thirds of the lost time cases return to work on Monday. If recovered workers could be induced to return to the job as soon as they are able instead of waiting until the beginning of the succeeding week, a lot of lost time would be saved.

LYNCH, D. L. Industrial Health and the War. *New Eng. J. Med.* 227, 6:209 (Aug. 6), 1942.

More about Polio—Though you may be aware of the present status of poliomyelitis control, you may profit from reading this clear and brief summary of the state of our understanding.

MILZER, A., and LEVINSON, S. O. Recent Research in Infantile Paralysis. *Pub. Health Nurs.* 34, 3:434 (Aug.), 1942.

Children in a "War of Nerves"—Health workers interested directly, or remotely, with the welfare of children will welcome this symposium which is an outgrowth of a course given to teachers in New York City public schools. Psychology has become a deadly war

implement. Methods of arming children against it are discussed.

PEPPARD, S. H., *et al.* Mental Hygiene and Children in War Time. *Ment. Hyg.* 26, 3:353 (July), 1942.

Sign of the Times—Leading article in this month's official publication of the Associated Industries of Massachusetts is the story of the state's committee on industrial health (a part of the larger Public Safety Committee). The committee's job is to gather scientific information about workers' health and to make this information available to employers and employees. Eleven more articles on industrial health will follow in succeeding issues of the magazine.

PRENDERGAST, F. M. Our Second Front—Worker Health. *Industry.* 7, 11:7 (Aug.), 1942.

Fitness To Fight—Of the first 2,000,000 men examined for the Army draft, half were rejected by the examining boards. Selective Service was given the job of rehabilitating one-fifth of these rejectees. Then came Pearl Harbor, and minor defects were no longer disqualifying. Correctible defects are listed, and what has been done in some centers to correct them is related.

ROWNTREE, L. G. Rehabilitation and Pre-rehabilitation. *J.A.M.A.* 119, 15:1171 (Aug. 8), 1942.

Spasm and Muscle Alienation—Clearly described nursing details in the application of the Kenny method of care during the acute stages of poliomyelitis will prove illuminating to any health worker who wants to know what all the shooting is about in this revolutionary change in treatment.

STEVENSON, J. The Kenny Method. *Am. J. Nurs.* 42, 8:904 (Aug.), 1942.

Syphilis in National Unfitness—Of the first million draftees 45,000 had serologic evidence of syphilis. The

second million will probably repeat the record. (We don't know the rates as of 1917—tests in those days were too new and expensive, and not used in the draft examination.) Only about half the discovered cases are being brought under treatment. Tolerated prostitu-

tion and failure to apply epidemiologic methods are tragically evident deficiencies in our warfare against this disease.

VONDERLEIR, R. A. The Impact of the War on the Venereal-Disease Problem. *New Eng. J. Med.* 227, 6:203 (Aug. 6), 1942.

ANNUAL MEETING INFORMATION IN REVIEW

TIME AND PLACE: 71st Annual Meeting, October 27-30, St. Louis, Mo. Meetings of related organizations, Saturday, October 24, Sunday, October 25, and Monday, October 26.

HOTELS: The New Jefferson and the Statler are the headquarters hotels. Their rates, and rates of other St. Louis hotels are given on page 1184.

MEETING: The Auditorium is meeting headquarters.

EXHIBITS: Auditorium.

REGISTRATION: Auditorium. Registration opens Sunday, October 25, at 8:30 A.M.

ADVANCE REGISTRATION:

Required for the Conference on Orthopedic Nursing, sponsored by the Joint Orthopedic Nursing Advisory Service, on Sunday, October 25, and Monday, October 26.

Required for the Eye Health Institute, sponsored by the National Society for the Prevention of Blindness, Inc., on Sunday, October 25, and Monday, October 26.

Urged for the Ninth Institute on Public Health Education, Sunday, October 25, Monday, October 26, and Tuesday, October 27.

PRELIMINARY PROGRAM: Published in the August *Journal*, pages 890-920. Supplementary information, September, pages 1066-1067.

FINAL PROGRAM: Available at the Registration Desk, Auditorium, from Sunday morning, October 25.

LOCAL COMMITTEE CHAIRMAN: Joseph F. Bredeck, M.D., Commissioner of Health, St. Louis, Mo.

THE HEALTH EXHIBIT

THE Health Exhibit held in connection with Annual Meetings of the Association conveys as much information, in the opinion of many delegates, as does the scientific program. At St. Louis, nearly 200 booths will be occupied by technical and scientific exhibitors. In most instances, the materials and equipment to be exhibited play some part in solving the problems of the emergency. A list of the technical exhibitors is published on page XXX of this issue. A complete description of each exhibit was published in the August *Journal*.

The Committee on Scientific Exhibits takes pleasure in announcing that space has been allocated thus far to the following organizations on behalf of exhibits on the subjects indicated:

Agricultural Marketing Administration
The School Lunch Program
American Bureau for Medical Aid to China, Inc.
China's Health in War
American Dental Association
Preventive Dentistry
American Medical Association
Health Education in the Doctor's Office
Dietary Deficiency Diseases

An Industrial Health Program for a County Medical Society
American School Health Association
Information Booth
American Social Hygiene Association
The Minor Genito-Infectious Diseases
American Society for the Control of Cancer, Inc.
The Value of Mice in Cancer Research
American Society for the Hard of Hearing
Prevention of Deafness and Conservation of Hearing
British Information Services
Britain's Wartime Nutrition
Children's Bureau, U. S. Department of Labor
Maternal and Neonatal Deaths, 1930-1940
Cincinnati Municipal Health Center
Planning a Health Center
Cleveland Health Museum
Exhibits on a Budget
Committee on the Hygiene of Housing, American Public Health Association
Housing Survey Procedures
Committee on Local Health Units, American Public Health Association
Department of Medical Genetics, Bowman Gray School of Medicine
Prevention of the Hereditary Diseases Which Wreck Childhood
East Side Health District, East St. Louis, Illinois
Activities of the East Side Health District
Farm Security Administration
Health Is Vital to War Food Production
Health Department of the City of St. Louis

Activities of the Health Department

 U. S. Public Health Service
 Two Million Selectees Blood Tested for
 Syphilis
 Care vs. Caries, from Boyhood to Soldier
 Aircraft Quarantine
 35 mm. Photofluorographic X-ray Units

HEALTH EDUCATION CENTER

ACCORDING to the Social Work Publicity Council, material is coming from all over the country for the display of health education specimens to be shown during the Health Education Institute and the Annual Meeting in St. Louis. The collection will be housed in the Health Education Center in the Auditorium, which the Publicity Council is conducting again this year for the Association. Portfolios, annual reports, booklets, bulletins, pictorial statistics, radio scripts, newspaper publicity, posters, and other public education media will be available for study. All the portfolios are being planned to bring the most useful ideas and information to health educators in the war period.

A special feature of the Health Education Center will be a consultation service open to those enrolled in the Health Education Institute. Monday morning, when there are only two scheduled round tables on the Institute program, has been designated as "consultation period." There will be

limited opportunity for delegates who do not attend the Institute to make appointments with the consultants at the Center at other times during the week.

The preliminary roster of consultants on your health education problems includes: Mary P. Connolly, Department of Health, Detroit; Mayhew Derryberry, Ph.D., National Institute of Health, Bethesda, Md.; Bruno Gebhard, M.D., Cleveland Health Museum; Ruth E. Grout, Ph.D., U. S. Office of Education, Washington, D. C.; Ira V. Hiscock, Sc.D., Yale University School of Medicine, New Haven; Marion McKinney, Department of Health, Health Education Service, White Plains, N. Y.; Lucy Morgan, Ph.D., Craven County Health Department, New Bern, N. C.; Delbert Obertueffer, Ph.D., Professor of Physical Education, Ohio State University; Edward A. Pool, Zurich Insurance Company, Chicago; C. E. Turner, Dr.P.H., Massachusetts Institute of Technology, Department of Public Health.

JOURNAL EXPANDS EDITORIAL STAFF

THE Editorial Board of the *American Journal of Public Health*, with the approval of the Executive Board of the Association, has announced the appointment, effective September 1, of two additional Associate Editors, namely, Martin Frobisher, Jr., Sc.D., of the Johns Hopkins School of Hygiene and Public Health, Baltimore, Editor of the *American Journal of Hygiene*; and James E. Perkins, M.D., Dr.P.H., As-

sistant Commissioner, New York State Department of Health, Albany. Leona Baumgartner, M.D., Ph.D., Director of the Division of Child Hygiene, New York City Department of Health, and Arthur P. Miller, C.E., U. S. Public Health Service, New York City, will continue to serve as Associate Editors.

The Editorial Board has announced that the circulation has reached an all-time high of 9,400 copies for the *Journal*.

APPLICANTS FOR FELLOWSHIP

In accordance with the By-laws of the Association, the names of applicants for Fellowship are officially published herewith. They have requested affiliation with the Sections indicated. Action by the various Section Councils, the Committee on Eligibility, and the Governing Council will take place at the St. Louis Annual Meeting.

Health Officers Section

Charles G. Baker, M.D., Assistant Health Officer and Venereal Disease Control Officer, Fayette County Health Dept., Lexington, Ky.

Arthur L. Barbakoff, M.D., M.S.P.H., Director, Lee County Defense Health Unit, Freeport, Ill.

Dwight M. Bissell, M.D., M.S.P.H., Health Officer, San Jose, Calif.

Monroe F. Brown, M.D., M.P.H., Director of Local Health Service, State Department of Health, Nashville, Tenn.

W. D. Burkhalter, M.D., M.P.H., Assistant Health Officer, Memphis and Shelby County Health Departments, Memphis, Tenn.

Jose Chaves, M.D., Director, Public Health Units, Puerto Rico Health Department, Santurce, P. R.

Robert C. Farrier, M.D., Director, East Side Health District, East St. Louis, Ill.

Lawrence W. Fitzmaurice, M.D., D.P.H., Chairman, Board of Health, Nassau, Bahamas, B.W.I.

Edward J. Godfrey, M.D., Health Officer, Waterbury, Conn.

James T. Googe, M.D., C.P.H., Senior Medical Officer, Farm Security Administration, Denver, Colo.

Donald M. Harris, M.D., M.S.P.H., District Medical Director, State Health Department, Spencer, Iowa

John M. Hooper, M.D., M.P.H., Venereal Disease Control Officer, U. S. Army Medical Corps, McKinney, Tex.

Hugo V. Hullerman, M.D., M.S.P.H., Deputy

Commissioner of Health, Peoria, Ill.

Rutherford O. Ingham, M.D., M.P.H., Health Officer, Washington County Health Department, Jonesboro, Ala.

Lorin E. Kerr, Jr., M.D., M.S.P.H., Health Commissioner, Lorain County Health Department, Oberlin, Ohio

Leon R. Kramer, D.D.S., M.S.P.H., Director, Division of Dental Hygiene, State Board of Health, Topeka, Kans.

Charles J. Larkey, M.D., Health Officer, Bayonne, N. J.

Ezequiel Martinez-Rivera, M.D., M.Sc.P.H., Assistant Director, Bureau of Health Units, Department of Health, Hato Rey, P. R.

Sumner M. Miller, M.D., Commissioner of Health, Peoria, Ill.

George F. Moench, M.D., M.Sc.P.H., County Health Director, Calhoun County Health Department (W. K. Kellogg Foundation), Marshall, Mich.

John C. Neale, Jr., M.D., C.P.H., Assistant Director, Rural Health, State Department of Health, Norfolk, Va.

Jerome S. Peterson, M.D., M.P.H., District Health Officer, Department of Health, New York, N. Y.

John J. Poutas, M.D., M.P.H., Assistant to the Commissioner, State Department of Public Health, Boston, Mass.

Erwin C. Sage, M.D., M.P.H., Director, Des Moines County Health Service, Burlington, Iowa

James P. Sharon, M.D., M.P.H., Director of Venereal Diseases, State Department of Health, Lincoln, Nebr.

Jerome J. Sievers, M.D., M.S.P.H., District Health Superintendent, State Department of Public Health, Springfield, Ill.

Courtney Smith, M.D., Dr.P.H., Assistant Commissioner of Health, Territory of Alaska, Juneau, Alaska

Charles A. Steurer, M.D., Director, Division of Communicable Diseases, Nassau County Department of Health, Mineola, L. I., N. Y.

Harry Wain, M.D., M.S.P.H., Health Commissioner, Sidney and Shelby County, Sidney, Ohio

James P. Ward, M.D., M.P.H., Director, Washington County Health Department, Greenville, Miss.

Laboratory Section

L. A. Barnes, Ph.D., Lieutenant, Epidemiology and Sanitation, U. S. Navy Medical School, Bethesda, Md.

Stanhope Bayne-Jones, M.D., Lieutenant Colonel, U. S. Army Medical Corps, New Haven, Conn.

Walter J. Beichert, M.D., Bacteriologist and Chemist, Lindsay Laboratories, Brooklyn, N. Y.

George D. Brigham, Ph.D., Officer in Charge, Typhus Research Laboratory, U. S. Public Health Service, Savannah, Ga.

Claude P. Brown, M.D., Assistant Director, State Department of Health Laboratories, Philadelphia, Pa.

Elizabeth C. Brown, M.S., Serologist, State Department of Health, St. Louis, Mo. (On leave of absence)

William D. Dotterer, B.S., Director of Laboratories, Bowman Dairy Company, Chicago, Ill.

Lloyd D. Felton, M.D., D.Sc., Senior Surgeon, U. S. Public Health Service, Washington, D. C.

Earl W. Flosdorf, Ph.D., Assistant Professor of Bacteriology, University of Pennsylvania, Philadelphia, Pa.

Jules Freund, M.D., C.P.H., Assistant Director, Bureau of Laboratories, New York City Health Department, Otisville, N. Y.

Elizabeth F. Genung, M.S.A., Associate Professor of Bacteriology, Smith College, Northampton, Mass.

Albert H. Harris, M.D., Bacteriologist, Division of Laboratories and Research, State Health Department, Albany, N. Y.

Margaret R. Harrison, M.A., Chemist, U. S. Public Health Service, U. S. Marine Hospital, Staten Island, N. Y.

J. V. Irons, Sc.D., Associate Director of Laboratories, State Department of Health, Austin, Tex.

Felix R. Leycegui, D.D.S., Viena 26, Oficina de Especializacion Sanitaria, Mexico D. F., Mexico, Chief of Service, Dental Division, Public Health Dentistry

DECEASED MEMBERS

Emily M. Duntz, Geneva, N. Y., Elected Member 1941, Public Health Education Section

G. W. Luckey, M.D., Austin, Texas, Elected Member 1924, Health Officers Section

George M. Price, M.D., New York, N. Y., Elected Member 1912, Elected Fellow 1922, Industrial Hygiene Section

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

U. S. CIVIL SERVICE COMMISSION

The Commission has announced again its need for public health nursing consultants in war work. The new announcement now provides for 5 grades and for appointments in the Children's Bureau, Department of Labor, U. S. Public Health Service, and Federal Security Agency. Salaries range from \$2,600 to \$5,600 a year. No age limits have been set. Positions exist both in the United States and foreign countries. War service appointments will be made to extend generally for the duration of the war and no longer than 6 months afterward. Duties are to carry out, in accordance with the rank of the position, nursing or nursing education programs; and to act in advisory capacity to Federal agencies, or to State, County, and municipal organizations.

There will be no written test, qualifications being judged solely from review of experience, education, and training of applicants. Persons applying must have completed a 4 year course in a recognized college and 1 year's special program of study in public health nursing approved by the National Organization for Public Health Nursing; must also have graduated from an accredited school of nursing affiliated with a hospital having a daily average of 100 or more bed patients; be registered nurses in a state or territory of the United States or the District of Columbia, and have had appropriate general public health nursing supervisory experience. Additional credit given for completion of approved college course in statistical analysis, public health nursing, supervision, social hygiene, tuberculosis control and maternity, pediatric or orthopedic nursing; also for certain appropriate experience as instructor, consultant, or investigator.

For positions in Children's Bureau additional progressive experience in spe-

cialized fields of maternal or child health is required for the top grade and may be substituted for part of the general experience prescribed for the other grades.

Applications must be filed with the U. S. Civil Service Commission, Washington, D. C. and will be accepted until the needs of the service have been met. Forms may be obtained direct from the Commission or at any first or second class post office.

Merit System Council, Oregon State Board of Health and Crippled Children's Division, has announced merit examinations in practically all professional public health fields, including Health Officers, Nurses, Sanitary Engineers, Laboratory Workers, Vital Statisticians, Consultants in the fields of Health Education, Hearing and Vision, Nutrition, Oral Health and Physiotherapy. Two clerical positions, Fiscal Worker and Administrative Clerk are included in this list as is also the position of Merit System Personnel Technician.

Interested persons may get full particulars regarding the positions and examinations by writing H. J. Sears, Merit System Supervisor, P. O. Box 88, Portland, Ore.

The Indiana State Personnel Division, 141 South Meridian Street, Indianapolis, announces that applications may be filed at any time until further notice for the following positions:

Orthopedic Nursing Consultant I (women only)...	\$150-200 mo.
Physician I (General)	165-250 mo.
Physician II (General)	250-325 mo.
Physician II (Tuberculosis)	250-325 mo.
Physician I (Psychiatric)...	185-265 mo.
Physician II (Psychiatric)...	250-325 mo.
Local Public Health Director	300-360 mo.

POSITIONS AVAILABLE

Western state department of health will consider applications from physicians to fill four existing vacancies among county health officers, one vacancy in venereal disease control and positions as

laboratory technicians. Write Box S, Employment Service, A.P.H.A.

Physician with either public health training or experience in local health de-

partment administration to serve as health director in a county or district health department in midwestern state. Salaries vary from \$4,000 to \$4,500 with \$500 to \$600 travel, flat rate. These are well established health departments. Write Box T, Employment Service, A.P.H.A.

County Public Health Nurses for New Mexico. Must have 4 months' post-graduate instruction under one of the recognized public health nursing courses and 1 year's experience. Must drive and have a car. Address inquiry to State Health Department, Santa Fe, N. M.

PUBLIC HEALTH ENGINEER

Responsible professional public health engineering involving field investigations

and office studies in the application of sanitary measures. The more difficult engineering and sanitation field surveys include supervision over public water supplies, sewerage systems and sewage treatment plants and review of plans for same, and promotion and supervision of sanitation programs. Minimum qualifications: Training and experience equivalent to 3 years' civil engineering experience, including 2 years in public health or sanitary engineering; or completion of an academic year of graduate study and a year's experience in sanitary or public health engineering; and graduation from a college of recognized standing with a major course in civil or sanitary engineering. The salary range is \$205 to \$250 per month depending upon experience. Apply Box E, Employment Service, A.P.H.A.

THE AMERICAN RED CROSS NEEDS EDUCATORS

The American Red Cross will employ hundreds of social welfare workers and educators before January, 1943. These new employees will perform Red Cross services to the military units both in this country and with the task forces abroad.

Red Cross workers give counsel to the men in the armed forces about their personal and family problems, plan and organize recreational activities. They interpret Red Cross service to the military authorities. They act, to quote U. S. Army regulations, "in matters of voluntary relief and in accord with the military and naval authorities as a medium of communication between the people of the United States of America and their Army and Navy."

New professional employees needed include:

Men—Field directors, to serve at the military and naval centers here and abroad to counsel and advise men in the service regarding personal and family problems.

Men and Women—Club directors, program directors, staff assistants to operate clubs in leave areas overseas, some who qualify through executive or administrative experience, others by experience comparable to the operation of a large community center, and still others who qualify through recreation training and experience.

Men—Assistant field directors for recreation, to serve with the task forces overseas, qualified to plan, organize, and promote recreational activities such as sports, games, social recreation, entertainments, arts and crafts, music, dramatics, and game rooms.

Women—Medical and psychiatric social workers, case workers and recreation specialists in military and naval hospitals both here and abroad.

Men and women assigned to the service in this country will receive from \$135 to \$200 per month; those stationed outside the United States receive from \$150 to \$275 plus an additional \$50 per month maintenance allowance in military centers and full maintenance in club work. Uniforms are provided. Those Assigned abroad are also provided with certain insurance protection.

Those interested in receiving further information or in making application for a position in the American Red Cross Services to the Armed Forces program should communicate with: Personnel Service, National Headquarters, American Red Cross, Washington, D. C.

Those interested in a position within continental United States only should apply to the nearest Red Cross area office. They are as follows:

North Atlantic Area, 300 Fourth Avenue, New York, N. Y.
Eastern Area, 615 N. St. Asaph Street, Alexandria, Va.
Midwestern Area, 1709 Washington Avenue, St. Louis, Mo.
Pacific Area, Civic Auditorium, San Francisco, Calif.

THE AMERICAN NATIONAL RED CROSS WASHINGTON, D. C.

OTHER VACANCIES

Southwestern state health department seeks 2 physicians for assignment to district health units, personally to conduct several small venereal disease clinics on a rotating schedule. Experience preferred but not required. Salary \$3,000, plus actual travel allowance not to exceed \$1,200. Write Box V, Employment Service, A.P.H.A.

Wanted: Supervisor of generalized public health nursing staff of 6 to 8 nurses. Beginning salary \$175 per month, with opportunity for increase to \$220 and travel expenses. Must be high school graduate, graduate of hospital of 100 beds, and must have at least 1 year's postgraduate study in public health nursing at a recognized institution, and

2 years' experience in general public health nursing under qualified supervision. Apply Box L, Employment Service, A.P.H.A.

Mature woman physician, licensed in California, Minnesota and Indiana, desires to care for the aged, mentally disturbed, handicapped, epileptic, arthritic, etc., in the home or institution. A-505

HEALTH EDUCATION

Woman with master's degree in health education, 12 years' successful experience in public school and college teaching, administration and research. Will consider position in normal school, public schools, or in official or nonofficial health agencies. Prefers South or East. Available at once. H-501

INDUSTRIAL HYGIENE

Industrial hygiene chemist. Experienced in sampling, analysis of toxic industrial gases and fumes; petrographic dust analysis; dust counting; general toxicological analysis; chemical microscopy; also experienced in making industrial hygiene surveys, with knowledge of German, French, and Spanish. Six years' experience. Desires position. I-457

LABORATORY

Man, aged 28, A.B., M.S. in animal parasitology, Ph.D. in human parasitology and tropical diseases. Two years' experience in charge of parasitological diagnosis and research in state laboratory. Research publications; teaching experience. Desires teaching position in university with opportunity to do research. L-463

MISCELLANEOUS

Veterinary Doctor, M.P.H., University of Pennsylvania, aged 27, with 2 years of practice, seeks position in food, meat, milk or livestock sanitation with state or local health department. Also interested in teaching position with research facilities. M-451

Public Health Nurse with M.A. degree wishes position in health supervision and teaching in college or public school. West preferred. M-452

Administrative Assistant or Health Educator, woman, M.A., 10 years' experience in health agency offices; 7 years' teaching experience, writer on health and other subjects, experienced in independent research, some training in social work, some hospital experience. M-453

NEWS FROM THE FIELD

CRITERIA FOR DETERMINATION OF ESSENTIAL LIST OF PUBLIC HEALTH PHYSICIANS

THE Directing Board, Procurement and Assignment Service, has addressed to all State Chairmen for Physicians the following memorandum and has authorized its publication.

The Directing Board has approved the following recommendations made by the Advisory Committee on Public Health of which the members are: Carl V. Reynolds, M.D., State Health Officer, Raleigh, N. C., *Chairman*; Harry S. Mustard, M.D., DeLamar Institute of Public Health, New York, N. Y.; Reginald M. Atwater, M.D., Executive Secretary, American Public Health Association; Waller S. Leathers, M.D., Vanderbilt University, Nashville, Tenn.; and John L. Rice, M.D., Deputy Commissioner of Health, New York, N. Y., and President, American Public Health Association.

"A physician should be considered essential to civilian public health interests and, therefore, not available for military duty provided he comes within one of the two following categories:

- "1. A full-time medical officer in charge of a health service of a governmental unit or administrative district, such as state, district, county, and city.
- "2. Full-time heads or chiefs of administrative units within a health department. For example: tuberculosis, venereal diseases, maternal hygiene, infant care, epidemiology, vital statistics, etc.

"Methods of rendering health service differ throughout the states; public health problems vary with localities, population densities, and in terms of war industries, military centers, etc., which may create special problems where located. The committee, therefore, does not deem it feasible to submit any specific recommendations for

nation-wide application as to the essentiality of full-time medical officers serving health departments in capacities other than those in the two groups set forth above.

"In view of these facts, this committee recommends that the designation of physicians as essential in capacities other than those described above be determined after conference between the administrative chief of the health department concerned and the State Chairmen of Procurement and Assignment Service with the provision that except under unusual circumstances, physicians under 37 years of age—except for those specified in paragraphs 1 and 2 above—should be released for military service, their places to be taken by older persons or by those not eligible for service with the armed forces. Special consideration, however, shall be given to trained health officers who have had two or more years of training and service in public health. Furthermore, some of these who may not be essential locally may be needed by the U. S. Public Health Service for service elsewhere.

"If a State Chairman considers a public health physician as available, he should state *when available*."

CONFERENCE ON VENEREAL DISEASE CONTROL NEEDS IN WARTIME

VENEREAL disease and America's war effort will be discussed by high-ranking medical officers of the War and the Navy Departments, prominent physicians, health officers and others at a Conference in Hot Springs National

Park, Ark., October 21-24, 1942. Headquarters will be at the Arlington Hotel.

The Conference will be held under the auspices of the U. S. Public Health Service in conjunction with the Eighth Annual Meeting of the American Neisserian Medical Society. Surgeon General Thomas Parran will preside. State and local health officers, venereal disease control officers, practising physicians, and all others engaged in venereal disease control activities are invited.

Subjects for discussion will include venereal disease control measures influencing the war effort, epidemiology of syphilis and gonorrhea—1942, wartime venereal disease control education, research influencing the wartime venereal disease control program, and technics of venereal disease education.

Governmental, professional, and health organizations to be represented at the Conference include: the War Department, the Navy Department, the Social Protection Section of the Office of Defense Health and Welfare Services, the American Medical Association, the American Neisserian Medical Society, the American Social Hygiene Association, state and local health departments, and the U. S. Public Health Service. This Conference has been set immediately preceding the 71st Annual Meeting of the American Public Health Association in St. Louis, October 27 to 30, in the expectation that many persons would be able to attend both Conferences.

SENATE GETS BILL FOR MORE CHILD AID

PRESIDENT ROOSEVELT asked Congress on August 25 to amend the Social Security Act to make more money available to the Children's Bureau for "special needs of mothers and children arising from war conditions." Legislation to accomplish this was immediately introduced.

The President pointed out that war needs have made such heavy demands on the funds available through the Children's Bureau that additional funds, now prohibited by limitations written into the Social Security Act, must be made available through the amendment of the Act.

The amendment would raise the monetary restrictions imposed on the Children's Bureau for child welfare and would give the bureau permission to send special personnel into emergency areas.

The sum needed by the Children's Bureau until next July would be about \$7,500,000. According to a statement issued by Katharine Lenroot, head of the bureau, this sum represents almost double the present amount expended yearly and would be distributed as follows:

For more adequate health and welfare supervision in war industry boom towns—\$4,250,000

For maternity care for wives of service men—\$750,000

For child welfare workers to be stationed in trailer camps, war industry communities and other overcrowded areas—\$2,000,000

Miss Lenroot pointed out that the allocation of money for the wives of service men was a new departure brought about by the requests of about 38 states for financial help in providing adequate maternity care for these women. One of the reasons for naming such a large sum for child welfare workers, Miss Lenroot said, was that the problem of juvenile delinquency was a growing and dangerous one in crowded areas.

The money will be disbursed through grants-in-aid to the states. President Roosevelt said:

"I make these suggestions for federal assistance to the states in full appreciation of the fact that the degree to which children are safeguarded in wartime depends chiefly upon the parents in our homes, the teachers

in our schools, and the citizens of our communities.

"It is my hope that in making our supreme war effort, parents and citizens will be at all times on guard to see that children are safeguarded to the utmost from the dangers of wartime and equipped to use and to cherish the freedom which we shall make secure for them."

Under the terms of the amendment, all supplementary appropriations obtained by the Children's Bureau for war work will be allotted to the states on the basis of need and the money will not have to be matched in amount by state funds.

NUTRITION FOUNDATION PROGRAM

THE Nutrition Foundation, Inc., New York, N. Y., an organization sponsored by food manufacturing concerns, announced recently through George A. Sloan, its President, the receipt of additional funds of \$75,000 from six new member organizations for the purpose of nutrition research, bringing the total of the Foundation's funds available for this purpose to \$923,500.

At the same time, Charles Glen King, Ph.D., Scientific Director of the Foundation, announced the establishment of *Nutrition Reviews*, a monthly journal of interpreted progress in the science of nutrition. Its purpose will be "to bridge the gap between basic research findings and their acceptance on the part of those who deal with the public and to enable the public to keep abreast of current progress and to have available an unbiased, authoritative review of current literature."

The editor of the new publication will be Frederick J. Stare, M.D., Assistant Professor of Nutrition and Biochemistry at Harvard Medical School and the Harvard School of Public Health. According to Dr. King, *Nutrition Reviews* will be so edited as to merit the full confidence of the medical and other professions, including that of dentistry, nutrition, health

workers in general, teachers, dietitians, science writers, and food technologists. Assistant editors will include Esther Batchelder, Bureau of Home Economics, Washington, D. C.; Franklin C. Bing, Council on Foods and Nutrition, American Medical Association; R. Adams Dutcher, Pennsylvania State College; Robert S. Goodhart, Nutrition Division, Office of Defense, Health and Welfare; Carl V. Moore, Washington University; and Elmer J. Stotz, Harvard University.

The editorial advisory committee of *Nutrition Reviews* will consist of Reginald M. Atwater, M.D.; Samuel W. Clausen, M.D.; George R. Cowgill, Ph.D.; Conrad A. Elvehjem, Ph.D.; J. Murray Luck, Ph.D.; James S. McLester, M.D.; Henry C. Sherman, Ph.D.; Russell M. Wilder, M.D.; and John B. Youmans, M.D.

RESOLUTIONS FROM THE CANADIAN PUBLIC HEALTH ASSOCIATION

AT its annual meeting in Toronto last June, the Canadian Public Health Association passed the following resolutions:

1. Be it resolved that the thanks of this Association be extended to the American Public Health Association for making possible, in coöperation with the W. K. Kellogg Foundation of Battle Creek, Mich., the conduct of the 5th Annual Canadian Rural Health Conservation Contest; and for their coöperation with the Metropolitan Life Insurance Company in providing, for the second year, the Canadian City Health Conservation Contest.

2. Be it resolved that the Canadian Public Health Association express to the American Public Health Association its appreciation of the Manitoba Health Study as a contribution to the promotion of provincial health departments in Canada.

PUBLIC HEALTH AS A FOUNDATION FOR PUBLIC MORALE

THE testimony of a panel of persons engaged in public health who were invited to appear before the Tolan Committee of the House of Representa-

tives, January 15, 1942 (*American Journal of Public Health*, February, 1942, pages 226-228), will be found available in Part 25 of the Washington Hearings of the Tolan Committee "Testimony relating to the maintenance of civilian morale," pages 9834-9884. The Hearings document the relationships between public health and morale in this country and in England and may be used as source material for those supporting health budgets, etc., during the emergency.

Following this testimony, an excellent statement on the activities and operations of the British Ministry of Health is included with the statement of the Right Honorable Malcolm MacDonald, High Commissioner for Great Britain in the Dominion of Canada. Mr. MacDonald during the blitzkrieg was British Minister of Health.

CLEVELAND HEALTH MUSEUM RECEIVES GRANT

FOR the second time the Cleveland Health Museum has received a grant from the Thomas H. White Trust Fund, in the amount of \$1,100. This grant has been made to establish a permanent exhibit on nutrition and health at the Museum. According to Dr. Bruno Gebhard, Director, the opening of the exhibit is scheduled for the early part of January, 1943.

KANSAS STATE BOARD OF HEALTH ELECTIONS

FORREST L. LOVELAND, M.D., Topeka, and Hugh A. Hope, M.D., Hunter, have been appointed members of the Kansas State Board of Health. George I. Thatcher, M.D., of Waterville, was reelected President of the Board and Harry L. Aldrich, M.D., Caney, was elected Vice-President at a recent meeting. Floyd Z. Beelman, M.D., Topeka, who has been Acting Secretary, was appointed as Secretary and Executive Officer. William Fred

Mayes, M.D., Kansas City, was appointed the Director of Child Hygiene, and Harry R. Ross, M.D., Topeka, was appointed Medical Consultant to the Board.

STANDARDS FOR MATERNITY CARE AND EMPLOYMENT OF MOTHERS IN INDUSTRY

THE Children's Bureau and the Women's Bureau of the U. S. Department of Labor have issued a statement on standards for maternity care and employment of mothers in industry. Copies can be obtained from the Children's Bureau in Washington.

It is the opinion of the Bureau and a group of consultants that the labor situation in the United States does not now necessitate the recruitment or employment of pregnant women or women with infants. However, because some women who are pregnant or who have young children may find it necessary to seek employment, a statement of policy has been formulated to serve as a working basis for those concerned with the problem.

The statement outlines the facilities for adequate prenatal medical care, recommends that pregnant women should not be employed between 12 midnight and 6 A.M., nor more than 8 hours a day or 48 hours per week. It is recommended that pregnant women should not be employed in occupations involving heavy lifting or continuous standing. Other conditions involving accident risks and exposure to toxic substances are listed. A minimum of 6 weeks' leave before delivery is recommended and at least 2 months' leave after delivery.

MICHIGAN DEPARTMENT OF HEALTH HAS NEW BUILDING

THE *Journal of the A.M.A.* announces that a new building has been erected for the State Department of Health on the northwest edge of

Lansing. The four story construction was financed by state funds of \$135,000, supplemented by WPA grants of labor and material. Eleven of the twelve bureaus of the state department are located in the new building. Laboratory personnel will continue to occupy the former quarters.

CLARA ELIZABETH FUND FOR MATERNAL HEALTH

A RECENT decision of the Trustees of the Clara Elizabeth Fund for Maternal Health, Flint, Mich., separates the Fund's activities from those of the Flint Department of Health. Heretofore the program of the Fund has been directed by Flint's Executive Health Officer. The Clara Elizabeth Fund was created by a gift of General William S. Knudsen in 1937, when he was President of General Motors, to improve maternal health conditions in Flint and Genesee County. The classes designed to prepare both men and women for the responsibilities of parenthood were begun in 1939. Several meetings have been held each week since that time. More than 2,500 women and over 1,200 men have been enrolled in this unique educational program. The new arrangement decided upon by the Trustees does not alter the educational emphasis that has been the Fund's policy from the beginning. David B. Treat, who was Director of Health Education for the Fund, has been appointed its Director.

DIRECTOR OF MENTAL HYGIENE APPOINTED

DR. GERHARD B. HAUGEN of Portland, Ore., has been appointed Director of the Division of Mental Hygiene, established last year under the supervision of the U. S. Public Health Service. The new unit was set up by Dr. Curtis R. Chaffin, Portland, of the Public Health Service, who has been Acting Director. Dr. Chaffin is now

transferred to the U. S. Marine Hospital at Ellis Island, N. Y. Dr. Haugen is a graduate of the University of Oregon Medical School and has recently completed a year at Johns Hopkins University School of Hygiene and Public Health.

INDIANA SERUM CENTER CLOSED

THE Indiana State Department of Health has decided to close its serum centers, now located in different sections of the state, and distribute serum directly from the State Board of Health. The serum will be available on request and it is believed the new plan will not interfere with prompt delivery. This decision was made on the basis of a survey and the opinion of the pneumonia control committee of the State Medical Association.

"SNAPSHOTS OF DEATH"

THE U. S. Bureau of the Census, Washington, has announced the Mortality Summaries, a new series of releases in the *Vital Statistics Special Reports*, which will present statistical summaries for the more important causes of death. Each mortality summary will deal with a particular disease or cause of death and will give concisely in a few pages most of the salient facts about that selected cause. Each Mortality Summary contains in a compact and convenient 4 page release the essential information about one particular cause of death. Included in the tables are trends for the period 1900-1940, age-specific death rates, death rates by sex and race, death rates by month, contributory causes of death, death rates by place of residence, and other features.

Among the special reports already issued and available from the Bureau of the Census are Mortality Summaries on all causes of death, typhoid and paratyphoid fever, scarlet fever, whooping cough, diphtheria, tuberculosis, dysen-

tary, malaria, syphilis, measles, cancer, diabetes, exophthalmic goiter, pellagra, alcoholism, intracranial lesions of vascular origin, diseases of the heart, chronic rheumatic diseases, bronchitis, pneumonia and influenza.

NEW YORK UNIVERSITY COURSES IN INDUSTRIAL SAFETY

IN coöperation with the Greater New York Safety Council and the Newark Safety Council, the New York University Center for Safety Education will conduct during the 1942-1943 school year four special courses which have been designed to provide advanced training in industrial accident prevention and first-aid instruction for insurance and industrial engineers, inspectors, and others concerned with problems of industrial safety.

Instructors for the courses will include leaders in industrial safety and hygiene. The course coördinators will be Dr. Walter Cutter and C. Don Modica of the staff of the Center for Safety Education.

PERSONALS

Central States

ROLAND M. ATHAY, M.D., of Detroit, Mich., was appointed Medical Co-ordinator for the Wayne County Department of Social Welfare on May 26.

ALBERT C. BAXTER, M.D.,* of Springfield, Ill., formerly Illinois State Health Officer, has been appointed State District Health Officer with headquarters in Pana.

WILLIAM H. CAMERON, Chicago, Ill., Managing Director of the National Safety Council for the last 30 years, has retired, and has been succeeded by NED H. DEARBORN, Ph.D., of New York, N. Y., who has been named Executive Vice-President and Managing Director. Dr. Dearborn

has been Dean of the Division of General Education of New York University since 1934 and has been actively interested in accident prevention, having been Vice-President for Education of the National Safety Council for two years.

GARRETT J. FLANAGAN, M.D., of Kaukauna, Wis., has been appointed City Health Officer, to succeed CHARLES D. BOYD, M.D.

DENMAN T. GAMMELL, M.D., of Ulysses, Kans., has been named Health Officer of Grant County.

H. H. GERSTEIN, CH.E.,* of Chicago, Ill., has entered the Sanitary Corps of the U. S. Army, as of August 31. He was Sanitary Engineer in charge of the water safety control section of the Bureau of Engineering of the City of Chicago for the last 17 years.

GILSDORF GROFF, who has just completed his training for a Master of Public Health degree at the University of Michigan, has been appointed Engineer for the Regional Health Service at Valley City, N. D. With the exception of a 9 months' educational leave, Mr. Groff has been with the North Dakota State Department of Health since 1938 as Engineer in Charge of Laboratory Service.

G. R. HARRIS, formerly Superintendent of Public Health for the City of Detroit, Mich., has been appointed Hospital Administrator at the Herman Kiefer Hospital, Detroit; and FRANKLIN H. TOP, M.D., D.P.H.,* Director of the Division of Communicable Diseases and Epidemiology of the Detroit City Department of Health and the Hospital, has been named Medical Director.

ELMER L. LAMPE, M.D., of Bellevue, Ia., has been appointed Health Officer of Lamotte.

JOHN L. LAVAN, M.D.,* Health Commissioner of Toledo, Ohio, has been granted a leave of absence to accept active duty as Commander in the

* Fellow A.P.H.A.

† Member A.P.H.A.

Medical Corps of the U. S. Navy. OTTO F. C. LEHMBERG, M.D., Columbia City, Ind., has entered the Army Medical Corps and has been succeeded as Health Officer of Whitley County, by ARTHUR LEITER, M.D., of Columbia City.

HERMAN M. LYNCH, M.D., has been appointed Health Officer of West Bend, Wis., filling the vacancy caused by the resignation of WILLI-BALD J. WEHLE, M.D.

CARL W. PLOWMAN, M.D., of Jewell, Kans., has been appointed Health Officer for Jewell County, succeeding the late SPENCER B. DYKES, M.D., of Esbon.

SHERMAN T. ROGERS, M.D., has been appointed Health Officer of New Albany, Ind., succeeding ADDIS N. ROBERTSON, M.D., resigned.

VIOLA RUSSELL, M.D.,† who has been Director of Maternal and Child Hygiene of the North Dakota State Department of Health, Bismarck, N. D., since January 1, 1940, has resigned to accept the position of Director of Maternal and Child Hygiene for the Vermont State Department of Health.

FLORENCE LEE SCOTT has just been appointed Orthopedic Nursing Consultant by the North Dakota State Department of Health and the State Board of Public Welfare, according to Dr. F. J. Hill, Acting State Health Officer, and E. A. Willson, Executive Director of the State Welfare Board. She will divide her services equally between the two state departments. Mrs. Scott was Public Health Nurse for LaMoure County from 1939 to 1941, at which time she was granted a leave for a special course in orthopedic nursing at Western Reserve University.

E. L. SEDERLIN, M.D.,† formerly Health Officer for Fargo, N. D., will

be the Regional Health Officer at Valley City, N. D., replacing R. G. WHITE, M.D.,* now located at Bismarck.

JEROME SVORE, Sanitary Engineer for the Regional Health Service at Valley City, N. D., has been appointed State Milk Sanitary Engineer with the North Dakota State Department of Health at Bismarck. Mr. Svore joined the State Health Department staff November 8, 1938. Prior to his appointment with the Health Department, he was Assistant Construction Field Engineer for 13 counties in the Mandan District of the WPA.

ARTHUR F. WEYERBACHER, M.D., has been appointed to the Indianapolis Board of Health for a 4 year term succeeding GEORGE W. KOHLSTAEDT, M.D., resigned.

R. G. WHITE, M.D.,* Health Officer for the Regional Health Service, at Valley City, N. D., has been appointed Director of Maternal and Child Hygiene for the North Dakota State Department of Health, as of September 15. Dr. White came to North Dakota on September 1, 1937, from Detroit, Mich., where he served as School Health and Medical Coordinator for the Detroit Health Department from 1930 to 1935, and Director of the School Health Service at Ann Arbor, Mich., from 1935 to 1937. He will be located at Bismarck.

EDWARD W. ZEMAN, M.D., has been appointed Health Director of Hibbing, Minn.

Eastern States

TRAVIS P. BURROUGHS, M.D., M.P.H.,* Secretary of the New Hampshire State Board of Health, Concord, has resigned, effective August 31, and has been commissioned a Surgeon in the Reserve of the U. S. Public Health Service, where he is now on

* Fellow A.P.H.A.

† Member A.P.H.A.

duty. He is succeeded by ALFRED LEO FRECHETTE, M.D., M.P.H.†

BERNARD D. DAITZ, M.S.P.H.,† formerly Field Consultant for the New Jersey Tuberculosis League, Newark, N. J., is on active duty with the U. S. Army, and is at the 64th Station Hospital, Fort Jackson, S. C.

ALFRED LEO FRECHETTE, M.D., M.P.H., for some years Deputy State Health Officer in New Hampshire, has been appointed by the New Hampshire State Board of Health as Secretary of the State Board of Health, succeeding TRAVIS P. BURROUGHS, M.D., M.P.H.,* resigned. Dr. Frechette is a graduate in medicine from the University of Vermont and of the Harvard School of Public Health, from which he received the M.P.H.

CHARLES E. GILL, M.D.,† State District Health Officer, Massachusetts State Department of Health, Westfield, has been inducted as Major in the Army Medical Corps and is temporarily stationed at Lovell General Hospital, Camp Devens, Mass.

JOHN B. HOZIER, M.D., of Boston, Mass., has been detailed as Acting Director of the Division of Genito-infectious Diseases in the Massachusetts Department of Health. He succeeds ERNEST B. HOWARD, M.D., M.P.H.,† who is now a special venereal disease control officer for the U. S. Public Health Service.

GUSTAVUS H. KLINCK, JR., M.D., of Troy, N. Y., was chosen President of the New York State Association of Public Health Laboratories, at its meeting in Schenectady, May 18.

PAUL O. KOMORA, of New York, N. Y., was recently appointed Assistant Secretary of the New York State Department of Mental Hygiene, Albany, N. Y., effective August 1. He had been Associate Secretary of

the National Committee for Mental Hygiene.

ESMOND R. LONG, M.D., PH.D.,* Professor of Pathology, University of Pennsylvania School of Medicine, Philadelphia, Pa., and Director of the Laboratories of the Henry Phipps Institute, has recently been elected an honorary member of the Society for the History of Medicine, Buenos Aires, Argentina.

STEPHEN V. LUDDY, D.D.S., M.P.H.,† of Philadelphia, Pa., has been appointed Dental Director for the North Dakota Public Health Department, Bismarck, N. D., effective July 15. Dr. Luddy graduated February 15, 1941, from the School of Public Health of the University of Pennsylvania, where he received the degree of Master of Public Health.

DR. GEORGE W. PATTERSON, Professor in Bacteriology and Director of Athletics at the Philadelphia College of Pharmacy and Science, Philadelphia, Pa., was chosen President of the Alumni Association of the College, for the ensuing year, at the recent annual meeting.

REUBEN F. REIDER, M.D., D.P.H.,† of New York, N. Y., U. S. Public Health Service, has been named Health Officer of the Champaign-Urbana Health District, succeeding WALTER C. EARLE, M.D.,* of Champaign, who has been granted a leave of absence to do special work for the federal government, it is reported.

EDWARD S. ROGERS, M.D., M.P.H.,* Assistant Commissioner, New York State Department of Health, Albany, has been made Director of the Office of War Nutrition Services in the State War Council, Albany, as an additional assignment from his duties in the Department of Health. The State War Council includes the interests of 6 departments or other agencies of the State Government as they participate in an extensive

* Fellow A.P.H.A.

† Member A.P.H.A.

nutrition program. The aim is immediate concentration of all available resources and personnel on the problem of nutrition of war workers in industry.

FREDERICK FULLER RUSSELL, M.D.,* Professor of Preventive Medicine and Epidemiology, emeritus, Harvard Medical School, Boston, Mass., was awarded the honorary degree of Doctor of Science by the University of Rochester, N. Y., at its annual commencement exercises, May 11.

DAVID D. RUTSTEIN, M.D.,† who has been Chief of the Cardiac Bureau of the New York State Department of Health, Albany, has been appointed on the staff of the Office of Civilian Defense, Medical Division, Washington, to organize instruction for physicians as Medical Gas Officer.

JOSEPH J. SMITH, M.D., of Easton, Conn., has been named Health Officer of Easton, succeeding WILLIAM H. COON, M.D.

FREDERICK J. STARE, M.D.,† has been announced by C. Sidney Burwell, M.D., Dean of the Harvard Medical School, Boston, Mass., as Assistant Professor of Nutrition. Dr. Stare is a graduate of the University of Chicago, 1940.

VESTA L. STONE, R.N.,† Executive Secretary of the Northern Worcester County Public Health Association, has presented her resignation, to be effective when her successor has been installed.

LAWRENCE M. TIERNEY, M.D., has been appointed Health Officer of West Haven, Conn., succeeding EUGENE N. COZZOLINO, M.D.

MYRON E. WEGMAN, M.D.,† formerly of San Juan, Puerto Rico, and now with the New York City Bureau of Child Hygiene, will direct a training unit at the Kips Bay-Yorkville Health Center to train new physicians em-

ployed by the Bureau to replace staff members called into military service. ISRAEL WEINSTEIN, M.D.,* Assistant Director, Bureau of Health Education, New York City Department of Health; Major, Medical Reserve Corps, U. S. Army, is on military leave from the Department of Health for active service in the Army.

Southern States

N. G. ANGSTADT, M.D.,† of Fayetteville, has been made Director of the State Bureau of County Health Work of the West Virginia State Health Department, Charleston. Dr. A. M. Price has been Acting Director of this bureau since the Director, Dr. Bruce H. Pollock, joined the Navy. Dr. Angstadt has been Director of the Fayetteville County Health Department for several years. He is being succeeded by DON V. HATTON, M.D., formerly Director of the Wetzel County Health Department and recently returned from Johns Hopkins, where he received his M.P.H. degree.

WALLACE E. BAKER, M.D., of Petersburg, Va., has been appointed Assistant Epidemiologist in the Division of Venereal Disease Control of the Virginia State Department of Health.

BESSIE MAE BEACH, M.D.,† Associate in charge of the Division of Child Hygiene of the Alabama State Department of Health, has been appointed Regional Medical Consultant in maternal, child health and crippled children services of the Children's Bureau of the U. S. Department of Labor, with headquarters in New Orleans, La.

* Fellow A.P.H.A.

† Member A.P.H.A.

- WILLIAM B. KING. He was recently appointed Regional Consultant on Emergency Medical Service for northern Virginia.
- PAUL W. BOWDEN, M.D., M.P.H.,† Acting Health Officer of Charlotte County, has been appointed Epidemiologist for Richmond, Va.
- LOUIS A. BREFFEILH, M.D.,† of Marksville, La., head of the Avoyelles Parish Health Unit, has been appointed in charge of the Iberia Unit, with headquarters at New Iberia, succeeding CHRISTOPHER L. MENGIS, M.D.,† who recently became President of the Louisiana State Board of Health.
- DAVID E. BROWN, M.D., of New Orleans, La., has been appointed State Health Officer and President of the Louisiana Board of Health, succeeding CHRISTOPHER L. MENGIS, M.D.,† of New Orleans. Dr. Mengis will continue his association with the Board as Assistant State Health Officer, and Director of the Division of Local Health Service. Dr. Brown is a graduate of Memphis Hospital Medical College.
- T. H. BRUCE, M.D., C.P.H.,† Director of the Hancock County Health Department, West Virginia State Department of Health, has resigned his position to enter the Army.
- WILLIAM G. CARNATHAN, M.D., of Henderson, Tex., has been appointed Health Officer of Rusk County, succeeding JESSE E. ROSS, of Henderson, who has accepted a commission in the U. S. Navy.
- FRANCIS B. CARROLL, M.D., D.M.D., M.P.H.,† recently Camp Epidemiologist at Fort Knox, Ky., was transferred on June 15 to the Preventive Medicine Section, Surgeon General's Office, War Department, Washington, D. C.
- JOHN S. CHAMBLEE, M.D., of Windsor, N. C., Health Officer for Bertie and Chowan Counties, will take over the work in Gates County, succeeding THOMAS G. FAISON, M.D.,† of Winton, Health Officer for Hertford and Gates Counties, who has entered active service.
- WILLIAM E. CHAPIN, M.D., of Richmond, Va., has been named to succeed WALLACE E. BAKER, M.D., of Petersburg, in his former position of Field Epidemiologist for the Camp Lee area, with headquarters in Petersburg.
- FRANCIS J. CLEMENTS, M.D.,† of Stony Creek, Va., has been named Health Officer of the new health district comprised of Dinwiddie County and Sussex-Prince George Counties.
- ERNEST A. COOK, M.D.,† recently Director of a health unit in Alabama, has been appointed Director of the Okaloosa-Walton County Health Department, with headquarters at DeFuniak Springs, Fla.
- GEORGE W. CRESWELL, M.D., has been appointed a special consultant in the Division of Venereal Diseases, U. S. Public Health Service, Washington, D. C.
- J. T. DUNCAN, M.D., of Columbia, Ky., who has been Health Officer of Adair County since 1937, has resigned to become Director of the Bureau of Tuberculosis of the West Virginia State Department of Health, Charleston, effective July 1. Dr. Duncan will have charge of the Mobile Tuberculosis X-ray Unit operated by the Division of Communicable Disease Control of the Health Department.
- BEVERLY L. HOLLADAY, M.D., of Wytheville, Va., has resigned as Health Officer of Wythe County, effective April 1.
- DANIEL HOPE, JR., M.D., of Lawrenceville, Va., formerly Assistant Health Officer of the Brunswick-Greenville-Mecklenburg Health District, has

* Fellow A.P.H.A.
† Member A.P.H.A.

been appointed Health Officer of the Alleghany-Botetourt Health District, with offices in Covington, succeeding WYATT E. ROYE, M.D.,† of Covington, who has been transferred to the Tuberculosis Outpatient Service of the Virginia State Health Department, at Richmond.

THOMAS H. JOHNSTON, M.D., formerly of Douglas, Ga., has been appointed Director of the Ontonagon-Baraga County Health Unit, succeeding ROLLA J. SHALE, M.D., M.S.P.H.,† of Ontonagon, who has gone to Florida.

GILBERT L. KELSO, B.A.† has been named sanitary chemist in charge of stream pollution with the State Water Commission of West Virginia. Mr. Kelso, who has recently returned from Minnesota where he did post-graduate work, takes the place of KENNETH H. WATSON, who is now in the Army. Mr. Kelso was formerly a member of the staff of the West Virginia Public Health Training Center at Morgantown.

J. H. MASON KNOX, JR., M.D.,* of Baltimore, Md., who recently retired as Director of the Maryland State Bureau of Child Hygiene, has been appointed Consultant in Child Hygiene. At a recent dinner marking his retirement, Dr. Knox was presented by his colleagues with a bound portfolio of his own work, including reprints of articles, addresses and reports of special studies.

L. A. MACLEAN, M.D., D.P.H.,† Director of the Monongalia County Health Department, West Virginia Department of Health, Morgantown, has been transferred to the Brooke County Health Department, succeeding DR. W. H. BOOHER, who has gone into the Army. Dr. MacLean will be replaced by DR. W. B. BAILEY, who has been loaned to the

West Virginia State Health Department by the U. S. Public Health Service.

FRANK A. MOORE, M.D.,† of Jackson, Tenn., has resigned as Regional Health Officer of West Tennessee, to become a captain in the U. S. Army Medical Corps.

PAUL Q. PETERSON, M.D.,† of Hardinsburg, Ky., has been transferred from his position as Health Officer of Hancock to a similar position in Warren County. He will succeed LEWIS FINE, M.D., of Bowling Green, who is retiring from the work because of ill health.

LESTER M. PETRIE, M.D.,† of Atlanta, Ga., has been named Director of the Industrial Hygiene Service recently created in its Division of Preventable Diseases by the Georgia State Department of Health.

STANLEY BROOKS RUSSELL, A.B.,† Statistician and Assistant Director of the Bureau of Records and Vital Statistics, Jefferson County Board of Health, Birmingham, Ala., has been commissioned First Lieutenant in the Army of the United States, and is now serving in the Bureau of Preventive Medicine, in the Office of the Surgeon General.

WILSON T. SOWDER, M.D., M.P.H.,† of Tampa, Fla., U. S. Public Health Service, who was Health Officer of Hillsborough County, has been placed in charge of the Bureau of Venereal Disease Control of the Florida State Board of Health. He succeeds LEO C. GONZALES, M.D., of Jacksonville, who has been in charge of the work for the last 4 years and who, it is reported, was to retire on May 1 to engage in private practice in Tampa.

J. FRANK TAYLOR, of Martin, Tenn., has been appointed State Supervisor of Health and Physical Education, to carry on the physical education program of the Tennessee State Department of Education.

* Fellow A.P.H.A.

† Member A.P.H.A.

WILLIE B. TRAMMELL, M.D., of Statham, Ga., has been named Health Commissioner in the newly established unit in Gwinnett County, with headquarters in Lawrenceville.

FRED J. WAMPLER, M.D.,* Professor of Preventive Medicine at the Medical College of Virginia, Richmond, Va., since 1928, has been named Professor of Preventive and Industrial Medicine.

Western States

FRANCIS RHOADS has resigned his position as Director of Vital Statistics with the State of Washington Health Department, Seattle, to accept a position as Director of the Division of Vital Statistics in the West Virginia State Health Department, effective July 6.

CHARLES E. SHEPARD, M.D.,* Professor of Hygiene and Director of Student Health at Stanford University School of Health, Palo Alto, Calif., has been called to active duty with the U. S. Public Health Service with the title of Surgeon, and is attached to the staff of FRED T. FOARD, M.D.,* San Francisco, Calif.

HAROLD B. STOUT, M.D., formerly of Pateros, Wash., has been appointed Health Officer for Douglas County, Ore.

Hawaii

KUM PUI LAI has been appointed Acting Executive Secretary of the Territorial Tuberculosis Association, Territory of Hawaii, it has been announced.

THEODORE R. RHEA, C.P.H.,† left his position, August 1, with the Tuberculosis Association of the Territory of Hawaii, to become Director of Palama Settlement. This position was originally held by PHILIP S. PLATT, C.P.H., PH.D.*

Puerto Rico

ANTONIO FERNOS ISERN, M.D., has been appointed as Commissioner of Health of Puerto Rico as of August 1, it has been announced. Dr. Fernos was Commissioner of Health of Puerto Rico for a period ending in 1933. He succeeds EDUARDO GARRIDO MORALES, M.D., DR.P.H.,* who has been Commissioner since 1933 until his recent resignation to enter the armed forces of the United States as a Major in the Medical Corps. ACOSTA VELARDE, M.D., was Acting Commissioner of Health during July.

DEATHS

ALLEN JONES JERVEY, JR., M.D., of Tryon, N. C., formerly District Health Officer for Rutherford and Pope Counties, S. C., 1st Lieutenant, Medical Reserve Corps, U. S. Army, died June 17 somewhere in the Pacific of gunshot wounds.

WINFIELD CAREY SWEET, M.D., of New York, N. Y., since 1921 a staff member of the International Health Division, Rockefeller Foundation, who has worked in China, Australia, Ceylon, and India, died May 20 in Bolivia of heart disease.

Health Education in Extra-Cantonment Zones^{*}

LUCY S. MORGAN, PH.D., F.A.P.H.A.

United States Public Health Service, Bethesda, Md.

SHIFTING soldier and civilian populations, housing shortages, prostitutes in battalions, and mushroom cafes by the score have forced extra-cantonment zones to take on the character of buffer states and given health officials the grave responsibility of maintaining health communities under the most unusual circumstances. But war has not really changed the basic principles upon which health programs are built; it has, however, demanded a recognition of special problems and a readjustment of all programs to cope with immediate needs.

I shall here describe a demonstration in community health education that is under development in the war areas of North Carolina.

Because the principal objective of the demonstration is to focus the attention of the public on health problems that have arisen and are arising in the war areas, those concerned with its planning

and organization recognized from the beginning that the best way to develop a health education program at this time was to relate it to the war effort and to utilize the untapped reservoir of lay leadership that is always present in a community.

The demonstration was launched early last fall when twenty-five of the leading women in one town were interviewed by a health education consultant, loaned to the State Board of Health by the U. S. Public Health Service and assigned to the county health department. The women were asked if they were at all concerned over the physical condition of the young men of the nation, as indicated by the draft figures, and whether they planned to do anything about the condition in their own community. They were also asked what they thought about other local health problems and whether they would be willing to sponsor a health education program in order that they might become better informed about these problems and their relation to defense. Every woman interviewed felt that there was a need for such a

^{*} Read before the Public Health Education Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

program and that a special effort should be made to develop one.

Upon completion of the interviews, a meeting was scheduled to which all the women of the community were invited. At this assembly it was decided that one organization designed for an all-out effort should be formed. A Central Planning Committee was elected to work out a plan of action and report back to the whole group. After that was done, at a subsequent meeting the organization selected as its name, "Woman's Committee Health Education Program for Defense" and listed the following as its objectives:

1. To make the town "the healthiest in North Carolina" by improving and protecting the health of every man, woman, and child in it.
2. To organize all the women, both white and Negro, into neighborhood study groups to prepare them for any emergency.

To make those objectives possible, the local Central Planning Committee devised a plan of action to reach every woman in the community. They divided the town into districts and then further subdivided the districts into blocks or neighborhood areas and selected a chairman for each. The "block" chairman accepted the responsibility of visiting every woman living in her area and inviting her to enroll in a neighborhood study group. The study groups were then scheduled to meet monthly at the home of the "block" chairman, to study and discuss health problems. Motion pictures and printed materials were provided for the meetings by the local health department.

Preceding the monthly neighborhood meetings, all the chairmen met to receive instructions and review the materials selected for group study. A representative from the local health department assisted with the meetings. Subjects selected by the committee for study were those of particular impor-

tance to the war area and included: the venereal diseases, nutrition, tuberculosis, dental care, sanitation, cancer, and colds.

The Negro population was reached through the same type of organization as the white and was given identical service by the local health department.

During November in addition to the regular monthly meetings, the Woman's Committee planned and operated a "Quiz Corner" under a famous old market house in the center of town. Although the "Corner" did not open officially until 10:00 a.m., volunteer workers began putting up exhibits and posters at 4:30 a.m., and other volunteers reported for duty throughout the day. The chairman for the day, who is a member of the Central Planning Committee, arrived at the "Corner" with a group of Boy Scouts at 7:30 a.m. and it was only after the last exhibit had been taken down, close to midnight, that she left her post.

The program was in charge of the white "district chairmen" during the day, while at night the Negro "district chairmen" took over. All were responsible for giving quizzes, explaining the health exhibits and assisting with the showing of motion pictures.

A crowd estimated at 5,000 persons came by the "Corner" during the day and night and over 300 persons took the quiz. Radio broadcasts direct from the scene were made three times during the day with prominent civic and health officials taking part.

The Woman's Committee also sponsored and prepared weekly radio programs, planned and wrote newspaper articles, gave "Victory luncheons" and organized classes for the Red Cross in home nursing and nutrition.

In March the committee made a community survey which was designated "Know Your City Day," and which proved to be of tremendous importance to the program. Eighty members of the

committee, working in teams of two members each, spent one day with all the agencies and organizations in the town that they felt made any contribution whatsoever to the total health program. Some of the places and persons visited were: clinics at the health department, the hospitals, presidents of medical and dental societies, Red Cross, the city welfare department, schools, public library, city recreation department, headquarters of the Boy and Girl Scouts, housing projects, United Service Organizations, jails, courts, restaurants, milk plants, the water plant, county agent, the Home Demonstration Agent, Farm Security Administration, and others.

After the survey had been completed and the Woman's Committee began to analyze their data, they were amazed at their findings—and particularly was this true of prostitution and venereal disease. A meeting with all chairmen was called and the facts were reported to them. They decided that something should be done immediately to remedy the situation, and scheduled a mass meeting and invited all city and county officials to attend. The whole question of prostitution and venereal disease, as it existed in the community, was reviewed in the most objective manner possible by members of the Central Planning Committee, and officials were requested to clean up the town and county or admit their unwillingness or incompetence to do so, in which case help from the federal government would be sought. In less than a week's time eighteen road houses and tourist camps were raided and padlocked and heavy sentences were given to the offenders. The people had spoken!

In order that town and county officials may be given continual encouragement to enforce the law, the Woman's Committee has appointed a working committee of thirty-one teams of two members each. Each team has a number

which corresponds to a calendar day and when that day arrives is responsible for attending all sessions of the court and keeping a record of all the cases tried. Teams are also responsible for attending any open meetings of the following which fall on the day assigned to them: Board of Education, Board of Health, Recreation Board, Welfare Board, and City Aldermen. Reports from all teams are given at the regular monthly meeting of the Woman's Committee.

As an example of how the working committee functions—one morning a young prosecuting attorney was having considerable difficulty in establishing a case against a taxi driver, a procurer, and a madam when suddenly he received a note from the back of the courtroom informing him of a local ordinance of which he was unaware. He immediately shifted his approach and the three were given 18 months. The note had been written by one of the members of the "working team" who was also a member of a special committee appointed by the Woman's Organization to study local ordinances.

Soon after the first unit of the demonstration in community health education was started, a second was begun in an adjacent county, and since that time four others have been launched and are in various stages of development. In general, the organization of these programs has followed the pattern of the first, but because of individual differences, each town and county has designed its program to meet its own health needs. Additional health education consultants have been loaned to assist with the development of each of these units.

In four counties the program operates as a part of Civilian Defense and the district is the air zone and the neighborhood area, the sector, but otherwise the plan of organization is the same. Rural women in these counties are reached

through the neighborhood delineation groups of the Agricultural Extension Service.

One of the significant accomplishments of these community health education demonstrations has been their stimulation of professional workers in four counties to form coördinating councils or councils of social agencies which will not only advise lay groups about immediate problems but also work out long-range plans to provide for future needs.

There are many other highlights in the various programs, most of which have come about by adjustments to fit local needs. In one county, in addition to the regular organized study program, the Woman's Committee has provided assistance for all the prenatal clinics in six towns and has been responsible, as well, for the establishment of a public health clinic in a town where formerly such a clinic had been opposed. These women also organized four quiz corners and arranged for 22 Red Cross courses to be given in 8 communities. The prostitution problem was also given their attention and, working with the law enforcement officers, they were able to bring about considerable improvement in the area.

In another county the woman's organization known as the "Health and Defense League" has sponsored a Family Living Program and a Children's Day Camp in defense housing projects. They also held a series of health meetings at a Negro migratory labor camp and, as a result, several men and women went voluntarily to the camp nurse to get treated for syphilis. The same Health Defense League assisted the Selective Service registrants in filling out their questionnaires and were responsible for organizing a county nutrition council. Medical authorities at a large shipbuilding establishment are supplementing the Health Defense League's program by showing the venereal dis-

ease film "Know for Sure" to all persons seeking employment.

In the fourth area which was organized, the health education unit consists of two counties. In one of these the Woman's Health and Defense League conducted a rat campaign as one of its first activities. Negro leaders in this county have been particularly strong and have been able to carry a much larger share of the responsibility for program development than in any other area. The fact that the health department has taken such an active part in the community health education program has stimulated the department itself to develop in-service training and to plan a series of lessons for food handlers. In this county the health department and Woman's Health and Defense League plan jointly for two 15 minute radio broadcasts each week.

In the second county of this unit the woman's program began with a house-to-house fact-finding and immunization survey. The health officer, more than any other unit of the demonstration, has taken an active part both in the organization of the groups and in the program itself. In addition to this, lay leadership in this county has been very superior and, as a result, the program needs less actual supervision than in any other area.

The last unit which has been developed to date is in its initial stage of organization, and future plans call for the extension of similar programs in all of the war counties of the state.

Probably the most significant result of the demonstration from the standpoint of health education is the fact that the North Carolina State Board of Health has made provision for adding eight health educators to the local health departments in the war areas and has provided for the training of these workers through the facilities of the School of Public Health at the University of North Carolina.

Perhaps some specific mention should be made of the materials which were used in these programs, since the question of materials is always one of vital importance to the development of any community-wide program in health education. Where and how can one get them? Who will pay for them and what materials actually are available for groups with different intellectual endowments and educational and racial backgrounds?

While these questions still remain unsolved, the wide variety of materials which are being used have been secured from many sources such as: U. S. Public Health Service, state health departments, U. S. Department of Agriculture, National Dairy Council, Metropolitan Life Insurance Company, and state universities. When the programs began, only three of the health departments in the demonstration area owned motion picture machines and their film library consisted of two films. Each department had pamphlets on many subjects, but they were not available in the quantity needed for county-wide study programs. Nor was there any money in any of the budgets for health education. Therefore, arrangements had to be made to secure materials elsewhere.

An interesting sideline which developed from the community health education demonstration during the summer was a malaria education project sponsored by the U. S. Public Health Service in seven southern states. In North Carolina nine teachers carried on intensive malaria education programs in seven counties, six of which were in the counties just described.

In two counties during the first 7 months of the demonstration, 328 meetings were held, with a total attendance of 40,984 persons. Motion pictures on various phases of health were shown 398 times and 74,990 pamphlets were distributed. Conferences on the program numbered 538. Thirty radio broadcasts

were given and over 75 articles about the program appeared in local newspapers. These figures do not include persons who did not attend the meetings but were reached by the "block" chairmen; neither do they include the Red Cross home nursing and nutrition classes which were organized as a part of the program, nor the home demonstration adult groups which used health materials loaned to them by the Woman's Committee. These figures are included in this description of the programs not because such statistics are at all a true index of health education, but so that some objective measure of the extent of community service may enter into the broader evaluation.

The figures that are really important are people—people who have found out for the first time that there are many problems in a community, problems that are all related and worthy of the consideration of every good citizen. Then, too, there are the *people* who admit that they have blocked other programs for years simply because they didn't know the facts; and there are those "southern ladies" who wouldn't mention words like "syphilis" and "gonorrhea" last September, but who only a few weeks ago were willing to spend hours in a venereal disease clinic learning the facts about the diseases and how they are handled by a health department.

There are the Negroes who, on a cold winter night or after a hard day's work, walked miles to see a health film and a few days later walked more miles to get a blood test. There is the school teacher who, after he saw a film on tuberculosis, went in for a chest examination and found that he had an active case of the disease. And the woman who knew she had a sore that needed attention but was afraid to find out the truth—until she saw a cancer film.

There are the women in mill towns who made house-to-house canvasses to urge mothers to take their

children to clinics to be immunized. These are the same women who came directly from the cotton mill looms with lint on their clothes to learn about health and take classes in home nursing so that they could do a better job in taking care of their children. And there are those people who have always thought that health departments were organizations to take care of the poor, mostly poor Negroes; but now know and appreciate the work being done. And the people who for the first time recognize that there is leadership at the "bottom of the hill" as well as at the top, and that everybody has a part to play in a true community program. And last, there are the staff members who were perfectly willing to devote several

nights a week to teaching health classes or to showing health films.

There are many other things that people have said or done that can never be told, but are true evaluations, nevertheless.

It has been well said that, "Doing things for people is often easy, but it is often expensive and of temporary benefit; showing people how to do things for themselves may take a little more time, but it is relatively inexpensive and its results are lasting."

Today more than ever before, health education has the opportunity to awaken in each individual a sense of responsibility which will enable him to assist in developing a community dedicated to human welfare.

Tetanus in Drug Addicts

During recent years the spread of malaria among drug addicts is quite common and its epidemiology well understood, a common syringe, and intravenous injections, sufficing to carry malaria parasites to a new host.

Sporadic cases of tetanus in drug addicts are not uncommon, and have usually been ascribed to wound infection through carelessness. The following outbreak, however, admits of no such explanation.

A group of 9 cases of tetanus in Negro drug addicts (8 fatal) was reported during December and January. The victims were all friends living within a few blocks of one another and pooling their resources to obtain heroin. Following this use of a common supply all developed symptoms of tetanus after varying intervals and were admitted to

a hospital where, with one exception, they died. Investigation showed that the heroin solution was prepared by placing the drug in water in a spoon and then warming sufficiently to dissolve. The use of a common syringe was denied, but each addict drew his allotted dose from the spoon. It is evident that the drug was contaminated with tetanus, although none of the material was available for examination.

Since this outbreak among Negro drug addicts, 3 additional cases of tetanus in white addicts have occurred. So far they cannot be linked to the Negro cases. It is possible that a substantial supply of narcotics coming from illicit sources may be contaminated with tetanus spores.—*Quart. Bull., City of New York Health Dept., Aug., 1942.*

Pulmonary Tuberculosis Resulting from Extra-Familial Contacts*

C. W. TWINAM, M.D., DR.P.H., AND ALTON S. POPE, M.D., F.A.P.H.A.

*Acting Superintendent, Lakeville State Sanatorium, Lakeville, Mass.; and
Director, Division of Tuberculosis, Massachusetts Department of
Public Health, Boston, Mass.*

IN recent years, numerous epidemiological studies have shown that tuberculosis not infrequently occurs in several members of a family. The disease may attack as many as four generations. The frequency with which multiple cases have occurred within a given household has tended to obscure the importance of contacts outside the immediate household.

In mass surveys there is not the opportunity for individualization of cases that is necessary to discover extra-familial sources of infection. Rural communities with low death rates from pulmonary tuberculosis have afforded excellent opportunities for demonstrating the importance of extra-familial contact in the spread of tuberculosis in the community. Downes has shown that extra-familial contact has played an important part in the spread of tuberculosis in a rural community.¹

The Massachusetts Department of Public Health recently conducted a 5-year survey on the control of tuberculosis in Berkshire County in Western Massachusetts. This county was considered to be representative of a rural community in New England and has next to the lowest death rate from

pulmonary tuberculosis of any county in the state. It was during these studies that our attention was focused on the importance of extra-familial contact in the spread of tuberculosis in the community. Figure 1 is a graphic representation of the spread of tuberculosis among several families as a result of extra-familial contact. The solution of this situation required a considerable period of time and a careful evaluation of certain obscuring factors. For this reason, the circumstances and clinical facts will be described in some detail.

In March, 1935, and August, 1936, two cases of pulmonary tuberculosis were reported in a small community of approximately 4,000 persons. Both cases were high school girls, aged 18 and 16 respectively. They were the only young persons in their respective homes. Members of family "A" were examined and were found to have no evidence of tuberculosis. Family "B" refused examination at the time but were examined subsequently and found to be entirely negative for tuberculosis. There was no history of tuberculosis in either of the families as far back as they could recall. Both households used raw milk from tuberculin tested herds. The milk supply was obtained from different dairies. The two girls were not "chums" but did attend the same high school.

A check with the school physician gave all of the teachers a clean bill of health, with the possible exception of

one. The latter had suffered from pulmonary tuberculosis two years prior, but was discharged from the sanatorium

as an arrested case. Further investigations in the community caused some doubt in the mind of the investigator regarding the teacher's physical condition, because several of the pupils complained to their parents that this teacher coughed during her classes.

The school physician made several sputum examinations, all of which were negative for tubercle bacilli. The charge that the teacher was a source of infection for the two girls did not seem justifiable in view of the repeated negative sputum reports and her denial of symptoms. Certainly the burden of proof was upon the person who said there was a causal relationship between the new cases and the teacher.

The situation rested at this stage until April, 1937, when the investigator was requested to see a patient in consultation. The patient was found to have pulmonary tuberculosis. She was a 19-year old girl who had been graduated from the same high school in 1936. Careful inquiry revealed that she had had little or no contact with either of the other girls at school. She had, however, during the time she was in school taken two courses given by the teacher who was under suspicion. A check-up by x-ray in her family revealed no evidence of active tuberculosis in any of the members, nor was there any family history of the disease. Again the evidence pointed to someone in the high school as a potential source of infection for these three girls. The teacher, aware that she was under suspicion and being somewhat embarrassed by the persistent questioning by the school physician, returned to the sanatorium outside the state for a check-up where she had formerly received treatment. A negative report was received by the school physician from the sanatorium.

Thus the situation remained until December, 1937, when a second request for consultation was received. This

time the patient was another high school girl aged 17. She had pulmonary tuberculosis. She, too, had had the same teacher in some of her classes. She knew all three of the girls but denied close friendship with them. Her family was examined by x-ray by a local physician who reported negative findings. Subsequent examination of these films confirmed the original report. At this stage there seemed to be almost overwhelming evidence that these girls had had a common source of infection, and the logical place to search seemed to be in the high school.

Further revisits were made to the families for the purpose of rechecking their contact histories. All families had used raw milk from tuberculin tested herds, but only two of the families took milk from the same dairy. It was during one of the visits to family "C" that a casual remark was made relative to a certain church which opened a new approach to the problem because it was known that family "A" attended the same church. Visits were made to families "B" and "D" and it was discovered that both of them also attended this church.

This was a remarkable coincidence. A rough statistical calculation placed the church under strong suspicion on the basis that in the school population considerably less than one-half of one case would be expected to have occurred by chance among this religious denomination if the source of infection were in the school. Thus attention was directed away from the high school. Inquiries were made regarding attendance of these girls at the church, which revealed that three of them sang in the choir and that all four of them had attended social functions at the church on numerous occasions.

A careful check-up of the reported cases and deaths in the community failed to show any of them to be members of this church.

During the investigations relative to the church membership it was learned quite by accident that the wife of the former minister in this parish had developed pulmonary tuberculosis and had entered a sanatorium in another state within 3 months after leaving this parish, early in 1936. This rumor was checked and found to be authentic. In fact, at the time of her admission to the sanatorium her pulmonary condition was advanced and her sputum was markedly positive. Further inquiry revealed that the minister's wife also sang soprano in the choir and took communion from a common cup before three of the girls who sang in the choir, as well as before the fourth who was not a choir member. Thus a common source of infection was found for these four girls in their fellow church member. On the basis of x-ray, sputum examination, and statistics, the school teacher, an arrested case, was eliminated from suspicion.

DISCUSSION

Aside from determining the true source of infection for these four girls, several other factors of epidemiological significance in the spread of tuberculosis in a community are manifested. It is well known that the commonest age at which death from tuberculosis in women occurs is between the ages of 20 and 25. There is also evidence at the present time to show that the age of highest mortality from tuberculosis is gradually shifting to the older age groups.² In this particular instance the range in age was from 16 to 19 years. All cases were girls, again revealing the importance of sex. We have in their age and sex two factors which have to be considered as contributing toward their susceptibility to pulmonary tuberculosis. A further factor of im-

portance so far as the spread of disease in a community is concerned is that three of these girls had positive sputum at the time the diagnosis was made. Two of them were moderately advanced and two were far advanced at the time of diagnosis. There was a high fatality rate. Two of the girls have already died from the disease, while one remains in a sanatorium, and the fourth has been discharged from a sanatorium as an arrested case.

Although three of these girls sang in the soprano section of the choir, while the fourth did not, there was ample opportunity for contact between the fourth girl and the tuberculous wife of the minister through social functions and the Sunday School. It was ascertained that these contacts were regular, usually once or twice a week, over a period of several years. The question of the use of the common communion cup is a "moot" one. It is reasonable to suppose that droplet infection through the contact at choir practice and social functions might well be sufficient to result in active disease in susceptible individuals such as girls of this age group.

The dosage of infection was probably fairly large if consideration is given to the cumulative effect resulting from frequent exposures at fairly regular intervals.

CONCLUSION

Failure to find a source of infection within a household should not preclude further attempts at finding the source case.

New York State Mutual Aid Plan for Water Service

EARL DEVENDORF

*New York State Water Coördinator, and Assistant Director, Division of
Sanitation, State Health Department, Albany, N. Y.*

THE world conflict has brought new problems to the United States. Never before have we considered our cities to be subject to bombing by an enemy force. The attack at Pearl Harbor shocked the country into sudden realization that what has happened in Europe during the past three years can happen here. We have become conscious of the fact that the wide expanse of the Atlantic and Pacific Oceans can no longer guarantee us safety from the aggressors.

It became necessary, therefore, to develop new plans for the protection of our civilian population. An important result is the plan for the protection of our public water supply systems and insurance of their prompt restoration in case of damage resulting from attack by the enemy. New York was one of the first states to inaugurate a Mutual Aid Plan for Water Service as an agency of the State War Council. Many other states throughout the country have patterned similar plans after it.

At the request of Governor Herbert H. Lehman, the New York State Department of Health and the Conference of Mayors appointed a committee of water works experts to formulate the Mutual Aid Plan for Water Service. Under the plan which was placed in operation in October, 1941, the state is divided into 22 zones which are coterminous with the boundaries of the existing state health districts, except for the separate

zones comprising Westchester, Nassau, and Suffolk Counties. An outstanding water works official has been appointed as zone coördinator in each zone and the district engineers of the State Department of Health and the county sanitary engineers of Westchester, Nassau, and Suffolk Counties hold appointments as assistant zone coördinators.

AUTHORITY

At the regular session of the 1942 New York State Legislature two bills were passed which relate to the Mutual Aid Plan and provide needed authority for carrying out its objectives. One law, constituting Chapter 544, set up a State War Council with wide, sweeping powers, and established a state office of civilian protection under the jurisdiction of the State War Council. The other law, constituting Chapter 574, provided for carrying out other specific objectives of the Mutual Aid Plan.

THE OBJECTIVES OF THE PLAN

A. *In the Field of General Preparations:*

1. The interconnection of public water supply systems.
2. The interconnection of public water supply systems with *approved* industrial or other water supply systems.
3. The preparation and maintenance of accurate maps of distributing systems or revision of existing maps to an up-to-date status.
4. The preparation and maintenance

of accurate records (books or otherwise) of the location of valves and other vital parts of the system.

5. The frequent testing of valves and fire hydrants to insure that these are in proper working condition at all times.

6. Collaboration with local fire officials in regard to—

a. Surveys and preparation for use of all possible emergency sources of water supply which may require pumping into the system during an emergency.

b. The characteristics of valves and fire hydrants and the needs for hydrant adapters.

c. Surveys of distribution systems to discover defects and weaknesses, and the development of plans for their correction, together with reinforcement of systems to the maximum degree possible.

7. Collaboration with local power and other utility officials in regard to conditions that may affect operation of the water supply in an emergency, and the measures to be taken to insure ability of the water system to function in event of the failure of other utility services.

8. Collaboration with local fire and war industry officials in regard to deficiencies in water service and fire protection furnished to war industries and coöperation in correcting such deficiencies.

9. The thorough study and consideration of the needs for protection against possible water works sabotage or fifth column attacks, and the adoption of such measures as are reasonable and consistent with the needs of each particular community.

10. The preparation of a detailed inventory of water works personnel, equipment, materials and supplies, and the submission of such data to the Zone Water Supply Coördinator.

B. In the Field of Civilian Protection:

1. Collaboration with local war coun-

cils and local directors for the purpose of integrating the civilian protection features of the Mutual Aid Plan with the plans of local councils and local directors.

2. Technical advisory assistance on all matters related to water supply to the State Director of Civilian Protection, his deputy directors and assistants, local war councils, and local directors.

3. The organization, training, equipment, and operation of water main emergency repair crews and other auxiliary or reserve water works personnel, to function through the local water superintendent under the local director.

PLAN OF ORGANIZATION

The Governor appointed the writer as State Water Supply Coördinator with A. F. Dappert, Principal Sanitary Engineer, State Health Department, as Assistant Coördinator, to direct the carrying out of the specific objectives of the Mutual Aid Plan. The writer was also appointed Director of a Division of Water Main Emergency Repairs under the State Office of Civilian Protection of the New York State War Council, to act as technical adviser to the State Director of Civilian Protection and as directing head of the plan on all matters relating to the organization, training, equipment, and operation of emergency repair crews and other auxiliary or repair water works personnel and other matters relating to the integration of the civilian protection features of the Mutual Aid Plan with the plans of local directors of civilian protection. The work of supervision and direction is decentralized throughout the state through the offices of the zone and assistant zone coördinators in the respective areas under their supervision.

A manual for the instruction, information, and guidance of local health, water, sewer, and milk officials, and chair-

men of local war councils and directors of civilian protection has been prepared. This manual describes not only the specific plans and preparatory steps which should be taken in advance of any emergency but also the detailed emergency organization which should be developed as a part of the civilian protection services which are necessary to maintain efficiently or permit restoration of these vital services. The manual also gives technical advice for the guidance of local authorities in meeting special problems involved in the preparation for and handling of serious emergencies and the procedures on which these vital services are integrated with the civilian protection plans of each community.

As a supplement to this manual of emergency sanitation services, a bulletin has been prepared designed to serve as a guide to the local directors of civilian protection and local water officials in the organization, development, and training of auxiliary or volunteer emergency water main repair crews and other auxiliary personnel assigned to emergency water service duty. This bulletin gives a detailed outline of the qualifications required for the volunteer personnel assigned to emergency water service duty and the extent of need for such personnel. Details of training courses for the proposed repair crews and instruction methods are also outlined. The latter program has been worked out in coöperation with the Bureau of Public Service Training of the State Department of Education and Municipal Training Institute of the New York State Conference of Mayors and Other Municipal Officials.¹

Five 3 day regional water service training schools were held throughout the state during July for the purpose of training and instructing the key municipal water works personnel in order that they may in turn be better prepared to act as instructors to the large number

of volunteer and civilian emergency repair crews to be organized by the Office of Civilian Mobilization.

The Bureau of Public Service Training of the State Education Department and the Municipal Training Institute of the New York State Conference of Mayors have given the services of their organizations and officers in conducting these schools. Similarly, the New York State Section, American Water Works Association, has offered assistance. These offers are greatly appreciated and have been gratefully accepted. In fact, without such assistance it would be practically impossible to assume the responsibilities required to carry out and hold these training schools.

ACCOMPLISHMENTS TO DATE

Some of the accomplishments of the program to date may be briefly summarized as follows:

1. Of a total of 286 proposed interconnections between water systems, some 210 have been installed. These are needed wherever possible so that, in event of failure of one supply, full or partial water service may be maintained by drawing upon the other.
2. 388 communities have submitted maps of water supply distributing systems. These records should be available at all central cities in the event of any emergency.
3. 398 communities have made surveys of possible emergency water supplies. The availability of such emergency sources of water supply may be extremely vital in case of any disruption or failure of the regular source of supply.
4. 230 communities have made surveys of their water distribution systems for weaknesses. The importance of correcting any deficiencies or weakness needs no emphasis.
5. 64 communities have made special studies of water service and fire protection to defense industries.
6. 41 communities have made special studies in coöperation with power officials.
7. 79 communities have already undertaken the organization and training of auxiliary water works personnel.
8. 179 communities have given special attention to protection against possible water works sabotage.
9. 688 communities have submitted inven-

ories of water works equipment, materials, supplies, and personnel.

There is no feature of the program that is of more importance today to our municipal authorities and water works officials than the mutual aid inventory of water works material, in view of the ever increasing difficulty of obtaining critical materials which may be needed on short notice in case of emergency. The availability of this information in ready reference form makes it possible to arrange promptly for the loan of needed material and equipment. In respect to this feature of the Mutual Aid Plan for Water Service, it can be stated that it is now substantially complete and in effective operation.

In this connection, the State Coördinator, with the coöperation of a specially appointed War Inventory Committee of the New York State Section, American Water Works Association, is making a survey with a view to establishing a central pool of information on available water works material. This inventory plan is being undertaken to coöperate with the War Production Board, the Office of Civilian Defense, and the Army and Navy authorities. It is a direct result of the War Production Board's order to the water works authorities of the cities of the country having populations of 50,000 and over to curtail their inventories to the December 31, 1940, level.

IMMEDIATE PROBLEMS FOR THE FUTURE

For the next few months it is the purpose of the State-wide Mutual Aid Plan for Water Service to concentrate efforts in the direction of integrating the local water departments with the civilian protection services of each community and to secure the organization and training of water main repair crews and other water works auxiliaries who will be urgently needed in event of actual emergency.

Another important task is that of arranging to have a responsible local water official represented at the Office of the Local Director of Civilian Defense with a complete and accurate record of the water works system available. This official must assume the responsibility of arranging for such representation and for prompt attendance at practice black-out trials in order that each water works employee and organized auxiliary will be available and ready for emergencies.

The importance of having the fire departments coöperate with the water departments has been emphasized from the very beginning of our program in New York State. It has been pointed out that the fire departments have been accustomed to depend upon the availability of public water systems for the required water to fight fires, and have ordinarily given little thought to the necessity of emergency supplies. Unless there is complete coöperation and exchange of information between the fire and water departments, so that the fire departments know where the emergency supplies are and how to use them, the water departments have wasted their time in arranging for such supplies.

It must be remembered that the Army authorities hold the water works superintendent in each municipality responsible for an uninterrupted supply of water for the continued operation of defense industries. In the event of bombing it is certain that public water and sewer systems will be damaged. It is essential, therefore, that the public works departments and water departments coöperate plans through civilian protection directors for the necessary equipment and personnel for making such repairs.

While the Mutual Aid Plan is a product of the war, experience in New York State in the few months that this plan has been in operation has shown that it will be of value even in peace

time. One wonders why the plan has not previously been considered. It certainly seems to be indicated that the plan with all of its benefits to the water

works of the country will be continued long after the present war.

Mental Hygiene Service in a Rural Area

New York State Health News for October 5 reports on the Suffolk County, New York, mental hygiene program, which has now been in operation more than one year and which, according to *Health News*, has already demonstrated the advantages of a type of rural health activity in promoting the broader aspects of public health service.

According to *Health News*, the Suffolk County Mental Hygiene Division is believed to be the first in the United States organized within a county department of health. It began to function April 1, 1941. Its objectives are to ascertain local mental health problems and to devise constructive ways of meeting them. The staff consists of the Director, George M. Lott, M.D., who is a psychiatrist, and one psychologist, two psychiatric social workers, and a secretary. The mental hygiene clinics

of the state mental hospitals conducted in the county continue to serve their own parole patients and community cases in their areas. The county health department mental hygiene unit is responsible for all juvenile court cases, and provides needed services to schools in outlying rural districts. The first year's service has included 250 cases, and about 500 children have been surveyed by group-testing methods. Of the school children tested, 11.5 per cent had learning disabilities, 14.5 per cent were found to be mentally deficient, and 6 per cent were neurotic. Major physical defects appeared in 5 per cent, while 33 per cent presented behavior and social problems.

Suffolk County's experience shows that the organization of a mental hygiene unit within the county department of health offers many advantages.

False Positive Phosphatase Test from a Thermophil in Pasteurized Milk

THEODORE C. BUCK, JR.

*Assistant Director, Bureau of Laboratories, Baltimore City Health Department,
Baltimore, Md.*

IN 1937 the Baltimore City Health Department adopted the Gilcreas¹ modification of the Kay and Graham² phosphatase test. Since then a total of twenty-one false positive tests have been obtained from pasteurized milk and cream from dairy plants where the equipment and the pasteurizing procedures were found upon careful inspection to have been operated properly. Interest in these positive tests developed as the number increased and no satisfactory explanation for them could be given. Leahy and others have shown that certain strains of bacteria are capable of hydrolyzing the substrate used in the phosphatase test.^{3, 2} Accordingly, these investigators have emphasized the need for caution in interpreting the results of phosphatase tests where excessive numbers of bacteria are present. Suitable control procedures for recognizing these "false positive tests" have been in use in this laboratory for several years past.*

A positive phosphatase test was obtained from bottled pasteurized milk produced by a certain dairy under supervision in November, 1941. The phosphatase reading of 0.12 mg. phenol per 0.5 ml. of milk was observed and the test remained positive after re-pasteurization in the laboratory.

The bacterial plate count was significantly low from 1 ml. of this milk incubated at 37° C. for 48 hours. How-

ever, the direct microscopic count gave approximately 15 million bacilli per ml. The organism observed showed a marked resemblance to *Lactobacillus thermophilus*. These findings suggested a thermophilic organism as the possible cause of the positive phosphatase test; and the problems presented seemed to warrant investigation.

The primary purpose of this investigation was to isolate the organism and study the morphological and biochemical characteristics. This work is reported below under the heading "Experimental." Attempts to ascertain if such a bacterium could produce a phosphatase enzyme in milk in a given day, during the pasteurization procedures, are reported subsequently in this paper under the heading "Bacterial Phosphatase."

EXPERIMENTAL

Isolation of the Suspected Thermophil

To ascertain if the suspected thermophilic bacillus was present in all pasteurized milk produced by a certain dairy and if it was in sufficient numbers to produce a positive phosphatase test, samples were requested from the beginning and the end of the pasteurizing process. These samples were divided into equal portions and were examined as received for total bacterial counts by the direct microscopic and plate methods. The two other portions were incubated at 52° C. for 19 hours and

* Unpublished data.

4. End of Run	60,000,000	640,000	0.14 —Positive 0.015—Control

* Mg. of phenol per 0.5 ml. of milk, Gilcreas modification

then examined as previously stated. All four portions were subjected to the phosphatase test. The results of these examinations are given in Table 1.

As indicated by the data in Table 1, the milk sample from the first of the run with low bacterial counts and a negative phosphatase test may be considered as normal milk. The sample from the end of the run shows marked increases in the direct microscopic and plate counts, with no change in the phosphatase test. Both samples, however, when incubated at 52° C. for 19 hours gave marked increases in the direct microscopic but not in the plate counts, and produced positive phosphatase tests, indicating that a thermophilic bacillus might be the agent responsible for the change.

To obtain the suspected thermophil in pure culture, it was decided to grow the organism in tryptone broth (T.B.), as suggested by Ayers and Johnson,⁴ for promoting the growth of *Lactobacillus thermophilus*. Tryptone agar was to be used for plating, and dilutions made with the T.B. so that large, well isolated colonies would be obtained. Three predominating, well isolated colonies were to be picked and transferred to tryptone broth and back to agar. Each set of the broth tubes and plates were to be incubated at the following temperatures, 37° C., 44° C., 52° C., and observed at 24 and 48

hours. This procedure was to be performed at least ten times before the organism would be considered in pure culture.

Good growth and large colonies were obtained from the broth and agar cultures respectively in 24 hours when incubated at 44° C. and 52° C. No growth was observed from those held at 37° C. The broth cultures were quite turbid in 24 hours and showed a marked sediment in 48 hours at 44° C. and 52° C. Two kinds of colonies were observed on all plates. Each kind when picked to broth and back to agar produced both kinds of colonies.

After at least ten transfers it was decided to try several media to observe colony formation. They were: (1) Old standard nutrient agar (O.S.N.A.), 1934 formula American Public Health Association⁵; (2) New standard nutrient agar (N.S.N.A.), 1939 formula American Public Health Association⁶; and (3) American Association of Medical Milk Commission's agar (A.A.M.M.C.A.).⁷ All platings were incubated at 44° C. for 24 hours and observed by the Buck Colony Counter.⁸

The O.S.N.A. gave two kinds of colonies which may be classed as the pin point type. Colonies from the N.S.N.A. and A.A.M.M.C.A. were from 3 to 5 mm. in diameter, with both kinds present, the latter agar giving slightly larger colonies. These colonies will be

described presently, including a third kind under cultivation. A total of 20 transfers were now completed, the thermophilic bacillus was considered in pure culture and the morphological characteristics were therefore studied.

Morphology

The organism was found to be rod shaped, at least during the greater part of its active life. It was of relatively large size, the smallest bacillary element measuring about 1 μ in length, and the longest about 6 μ . The diameter of the bacillus was approximately 0.4 μ . Long filaments of chain formation extending beyond the microscopic field may be formed. Such long chains were never observed in commercial pasteurized milk. The agitation during the pasteurizing process in all probability would break them up into groups of a few cells (Fig. 1, Plate A). They were observed from buffered tryptone dextrose broth and agar cultures (Fig. 2, Plate A). Certain cultures, especially those from O.S.N.A. slants 48 hours old and older, showed a high degree of pleomorphism. The organism produced bizarre or involution forms that range from coccobacilli to large club shaped or pyriform bodies. The swellings occurred terminally and sub-terminally and varied in size (Fig. 3, Plate A). At first the organism was thought to be a spore-forming bacillus, but smears made from agar slants, stained for spores and examined each day for 10 days, did not reveal any conclusive evidence of spore formation. No viable transfers were obtained after 72 hours' incubation at 44° C. Cultures subjected to 85° C. for 5 minutes could not be recovered when reinoculated into broth or agar slants. Cultivation on potato also failed to reveal spores. Observations for motility were made by the usual hanging drop method, except that the B.T.D.B. culture was maintained between 45 and 48° C. while

under observation. It was found to be non-motile. From very young broth cultures, 1½ hours old, the organism was found to be Gram-positive. Agar cultures 4 hours old or older were Gram-negative. Observations of very young cultures, 1½ to 3 hours old, in dark field, presented few pyriform types. Older cultures on less favorable medium showed many of these forms. They also contained many granules which suggested gonidia-like structures (Fig. 4, (c), Plate A).

Staining Reactions

The bacillus stains well with many of the ordinary dyes and procedures when the culture is not over 72 hours old. Older cultures do not take the dye so well and many organisms are seen only in outline form. They present a ghost-like appearance. Often after a culture is 48 hours old transfers fail to grow. This suggests a degeneration of the cells and may explain the poorly stained smears.

Cultivation

Observations of colony formation by the shake tube method revealed that larger colonies formed near the surface of the medium. Colonies became progressively smaller in the deeper layers of the agar. The bacillus may therefore be considered a facultative anaerobe but grows best aerobically.

As previously stated, three types of colonies were produced on agar. The largest colonies observed were obtained on a recently devised medium. It is buffered tryptone dextrose agar (B.T.D.A.).* Type A is a convex, raised, erose, translucent colony of approximately 1 to 2 mm. in diameter. Type B

* The B.T.D.A. formula is as follows: Agar 1.3 per cent (BBL.); Bacto-tryptone 1.0 per cent; potassium phosphate (K_2HPO_4) Baker's 0.1 per cent; dextrose 0.05 per cent; in distilled water. Sterilize twice, in autoclave with not over 5 lbs. pressure each day for 20 minutes or Arnoldize. Final pH 7.2 to 7.4. (Baltimore Biological Laboratories = BBL.)

PLATE A.

is a very thin, transparent colony, ciliated, and under certain lighting gives a pale blue hue. This colony is approximately 3 to 5 mm. in diameter and is usually observed in the deeper layers of agar. Type C, a surface colony, is similar in all respects to Type A except that it is usually larger, approximately 4 to 6 mm. in diameter, not

including the radial arms which may extend 1 cm. or more, depending upon the incubation period. On B.T.D.A. slants the growth is rhizoid, transparent, and somewhat difficult to observe with the naked eye, especially young cultures.

Broth cultures (B.T.D.B.)* are tur-

* Formula the same as B.T.D.A. except that agar is omitted.

bid, with some settling after 24 hours. Type C colony in broth often produces a filamentous growth similar to a tangled piece of string. This growth is often observed within a 2 hour period. On blood agar no hemolysis of the red blood cells occurs.

Temperature Relations

To ascertain the temperature for optimum growth it was decided to obtain the organism in as viable a stage as possible; then to submit culture transfers to the following temperatures, 37°, 44°, 48°, 52°, 60° and 62.5° C., and observe them hourly for visible growth, with the exception of the overnight period.

Rapid transfers were made by inoculating B.T.D.B. twice a day, at 9 A.M. and 5 P.M., for two days from cultures incubated at 44° C. Eighteen transfers to B.T.D.B. were made. Three transfers were then incubated at the previously stated temperatures. Observations for growth were made hourly by comparing the inoculated tube with an uninoculated control.

No growth was observed in 24 hours from the 3 transfers incubated at 37° C. Growth was observed within 2 hours in 5 of the 6 transfers incubated at 44° and 48° C. All 3 transfers submitted to 52° C. showed growth in 3 hours. Also those submitted to 60° and 62.5° C. However, the turbidity noted in these tubes incubated at the two latter temperatures were not as heavy. The temperature for optimum growth may be tentatively placed at about 52° C.

Thermal Death Point

The thermal death point was determined by the Chick ⁸ method, except that the 18 hour B.T.D.B. cultures were diluted in 10 ml. of broth so that direct

counts of approximately 1 million organisms per ml. were obtained for each series of three thin wall tubes to be submitted to the following temperatures: 64°, 64.5°, 65°, and 66.1° C. The suspensions were well agitated and samples taken every 5 minutes during the 1 hour exposure to heat. The temperature variation was $\pm 0.2^\circ$ C. When three 1 ml. portions of exposed culture were withdrawn and inoculated into B.T.D.B., incubated at 44° C. for 24 hours and failed to produce growth in 3 of the 3 portions, the culture was considered killed. The results are shown in Figure 1.

From the data presented in Figure 1, it may be seen that temperatures of 64° C. for 48 minutes, 65° C. for 30 minutes, and 66.1° C. for 18 minutes apparently destroyed the organism.

Resistance to Chlorine

Four trials to determine the resistance to chlorine were made with water washings from 24 hour cultures grown on B.T.D.A. The water suspension contained approximately 1 million organisms per ml. The concentration of chlorine was determined before and after adding the organisms, and found to be relatively unchanged. To 9 ml. of 1 p.p.m. of chlorine, 1 ml. of the organism suspension was added and exposed for 1 minute. Five 1 ml. portions were transferred to B.T.D.B. and incubated at 44° C. for 24 hours.

No growth was obtained from 20 such transfers and it was concluded that chlorine in a concentration as low as 1 p.p.m. was effective in destroying the thermophilic organism in 1 minute.

Maintenance

The organism may be satisfactorily maintained by transferring every 24 or 48 hours into B.T.D.B. or skim milk. The Cryochem process ⁹ used with skim milk has maintained the organism for over 30 days.

⁸ *The Theory of Disinfection. A System of Bacteriology*, Medical Research Council, London, 1:178, 1930.

Biochemical Reactions

The fermentative reactions were studied in a basal medium containing Bacto peptone 1 per cent, Bacto beef extract 0.3 per cent, and carbohydrates 0.5 per cent in distilled water, sterilized by autoclave with no pounds pressure on two consecutive days. The final pH was 7.4. Chlorphenol red was employed in 0.0024 per cent concentration as the indicator. The carbohydrates were inoculated from an 18 hour B.T.D.B. culture in the usual manner and incubated at 44° C. for 10 days before the final observations were recorded. Rubber caps were placed over the cotton stoppers to prevent evaporation of the media. In four successive trials fermentation with the production of acid but no gas was obtained from lactose, dextrose, mannose, saccharose, maltose, galactose, xylose, levulose, and raffinose. No acid was produced from mannitol, glycerol, arabinose, inositol, rhamnose, dulcitol, inulin, sorbitol, and salicin. Indol was not produced. Lactic acid was formed.* The ability of the organism to produce a bacterial phosphatase enzyme is explained in detail below. The organism produced slight acidity in litmus milk with no coagulation. No evidence of growth was observed from gelatine. Direct smears made and stained after 24 hours showed that growth had taken place in all media with the exception of gelatine.

Pathogenicity

To ascertain whether the organism was pathogenic for animals, or any toxic substance was produced in 48 hour broth cultures, the following procedures were carried out: Agar slant washings in 0.85 per cent NaCl and B.T.D.B. cultures containing approximately 1 billion organisms per ml. were injected intravenously, intraperitoneally,

and intracutaneously into rabbits, intraperitoneally and intracutaneously into guinea pigs and mice. Three animals were used for each test and the dosage varied from 1 to 0.1 ml. In this series of tests no illness or symptoms of any kind were observed for a period of 21 days. Twenty-four hour broth cultures were centrifuged at 2,000 r.p.m. and the supernatant fluid injected into animals as previously stated. No abnormal results were observed from the animal used in this series. The organism was repeatedly isolated from the pasteurized milk of a certain dairy during a 2 month period. No illness was reported from the consumption of this milk upon inquiry by the Bureau of Milk Control.

Frequency of Occurrence

The frequency of occurrence of this organism in pasteurized milk and milk products has been partially investigated. It has been isolated from pasteurized milk, cream, and skim milk of four Baltimore dairies. These isolations were obtained, oddly enough, during the winter months. Since then routine thermophilic platings have been made totaling 103 milk and cream samples. From these, 9 thermophilic organisms have been isolated. However, none of these strains have produced the bacterial phosphatase enzyme.

Identification

With the morphological and biochemical reactions obtained, identification of the thermophilic bacillus was attempted. Beaver¹⁰ identified 23 thermophils, and a survey of the literature to 1942 disclosed some 167 strains reported in all. From careful study this thermophilic bacillus does not completely correlate morphologically or biochemically with any of them. It does, however, possess many characteristics of the *Lactobacilli*, especially *Lactobacillus thermophilus*, but several

* The Friedmann method was employed. *A System of Bacteriology in Relation to Medicine*, 9:144, 1931.

strains of the latter organism when tested failed to produce the bacterial phosphatase enzyme. As this organism appears to be a new strain of the *Lactobacillus* group the name *Lactobacillus enzymothermophilus* is suggested.

BACTERIAL PHOSPHATASE

Production of the Bacterial Phosphatase

To determine the production of the bacterial phosphatase enzyme with a minimum of interference from culture media, etc., it was decided to proceed as follows: Agar slant cultures were grown at 44° C. for 24 hours. The agar washings were performed as rapidly as possible by forcing the distilled water out of the pipette with a rubber bulb and withdrawing it quickly without disturbing or touching the agar. The control suspension was distilled water in contact with uninoculated agar for twice the time it required to make the bacterial suspension. A direct count gave approximately 50 million organisms per ml. of the suspension. The suspension was then centrifuged at 2,000 r.p.m. for 35 minutes. The supernatant fluid was removed and the organisms resuspended in as small a quantity of distilled water as would permit rapid pipetting.

The suspension was then added to milk (negative to the phosphatase test) so that each ml. contained approximately 50 million organisms. In addition, 10 ml. of the suspension was placed in a mortar and ground aseptically with broken glass for approximately 2 hours. Some of the suspension was also resuspended in sterile distilled water. The phosphatase tests obtained on these samples are reported in Table 2.

From the data given in Table 2, it may be seen that there was a negligible difference in the phosphatase units of control number 1 and control number 8. The unwashed, the washed, the ground, the washed and ground organisms all gave negative phosphatase tests. The supernatant fluid in the milk and the supernatant fluid alone gave positive phosphatase reactions of 0.07 and 0.20 Gilcreas units respectively, indicating that the phosphatase of this thermophilic bacillus is extractable.

Effect of Variation in Temperature Upon Bacterial Phosphatase.

It seemed advisable to determine the effect upon the phosphatase of temperatures above those usually employed for pasteurization, because, if the enzyme is thermostabile, no control for the

TABLE 2
Phosphatase Tests on Inoculated Samples
Values in Gilcreas Units

phosphatase test seemed available. Conversely, if the bacterial phosphatase is thermolabile at temperatures close to or above the pasteurizing point, the significance of controls for the test became apparent. The latter was found to be the case, as the enzyme is destroyed at 85° C. and after boiling for 1 minute.

Production of Bacterial Phosphatase in Milk

To determine the production in the laboratory of the bacterial phosphatase in milk at pasteurizing temperatures that would at the same time parallel as closely as possible the commercial pasteurizing procedure, the following conditions were set up:

1. The maintenance of temperature within $\pm 1^\circ$ F.
2. The preheating period of 20 minutes
3. The constant agitation of the milk
4. The prevention of foam

The apparatus assembled consisted of a 10 gallon stainless steel pot containing water. A sterile, paper covered, 2 liter

pyrex beaker was securely wired to a ring stand and submerged in the water to within 2 inches of its top. Motor driven stirrers with sterilized propeller blades were placed in both the beaker and the water. Thermometers were held in place by clamps in the water and in the beaker. The temperatures were checked with a Bureau of Standards certified thermometer. A liter of low-count certified raw milk was placed in the beaker at 42° F. and the culture added so that each ml. of milk contained approximately 10,000 thermophilic organisms. The milk was then brought to pasteurizing temperature by gas flame in approximately 20 minutes. Samples were withdrawn every 10 minutes for the first 30 minutes and thereafter at hourly intervals as shown in Figure 2.

The data shown in Figure 2 give the results of three trials of certified raw milk inoculated with the thermophilic organism and pasteurized for over 5½ hours. The broth culture pasteurized

at 144° to 145° F. shows the destruction of the milk phosphatase to below the normal Gilcreas value of 0.04 within the 30 minute time period. The production of the bacterial phosphatase is observed after the inoculated milk had been pasteurized for 90 minutes. This may be considered a critical ordinate, as the production of the bacterial phosphatase begins at this time. During the next 30 minutes, 0.025 bacterial phosphatase units are produced, with no noticeable increase for the next 1 hour period. The total pasteurizing time was 3 hours for this production. There was no significant production of the bacterial phosphatase for the 120 to 180 minute period. The production during the next two periods of 1 hour each is rapid, and 0.06 and 0.12 phosphatase units respectively are produced. The total bacterial phosphatase produced during a 6 hour period of pas-

teurization was from 0.01 to 0.19 units for this trial. It should be noted that milk pasteurized for 3½ hours gave a doubtful or 0.048 phosphatase test.

The other two trials, pasteurized at 142° to 143° F., do not show the complete destruction of the milk phosphatase within the 30 minute pasteurizing period. The agar and broth culture inoculums, however, correlate the findings of Burgwald¹¹ and others who have established 0.12 to 0.15 Gilcreas units for pasteurizing milk at 142° F. for 30 minutes. Burgwald in one trial reports 0.04 Gilcreas units at 142° F. for 40 minutes. These results are pointed out because samples were not obtained for the phosphatase test between the 30 and 90 minute periods. Straight lines were used to connect these points, and it is therefore obvious that they would have fallen below the normal 0.04 value sooner had samples been tested. The

critical ordinates for the production of the bacterial phosphatase for these two trials are also after the 90 minute period. The production of the bacterial phosphatase from the broth culture inoculum is more rapid than that of the agar culture. The values obtained were 0.08 and 0.05 respectively for the 150 minute period. There is no apparent lag period at this pasteurizing temperature as there was for the 144° to 145° F. trial between the 120 and 180 minute period. The production of the bacterial phosphatase at this temperature is more rapid. Positive phosphatase tests of about 0.05 units from the broth and agar cultures at 120 and 150 minute periods respectively were obtained. The production of 0.1 and 0.15 phosphatase units, broth and agar cultures respectively, were obtained for the two trials at the 210 minute period. A slight but not significant amount of bacterial phosphatase is produced after this time period.

The average production of bacterial

phosphatase for the three trials in the critical 2 hour period was 0.14 Gilcreas

units. The maximum production during the 5½ hour period was 0.25 Gilcreas units.

Growth Phase of Thermophil to Phosphatase Production

To determine the number of thermophilic organisms necessary to produce a significant number of phosphatase units in low-count certified raw milk during pasteurization at 142° to 143° F., the following experiment was conducted. The procedures employed here are the same as those described under *Production of Bacterial Phosphatase in Milk*, except that direct microscopic and plate counts were made on each sample. All plate counts were made in duplicate, using three dilutions, and the technic of *Standard Methods for the Examination of Dairy Products*¹² was employed. The plates were incubated at 44° C. and the counts per ml. of milk are given in Figure 3. The following media were employed for the counts, heart infusion agar,* O.S.N.A. and A.A.M.M.C.A. Direct microscopic counts were also made. The O.S.N.A. counts at 37° C. incubation and the phosphatase curves are included in Figure 3 for the purpose of orientation.

The data given in Figure 3 show at the 90 minute period the phosphatase unit of 0.02 and the direct microscopic count of approximately 100,000 thermophilic organisms per ml. of milk. The O.S.N.A. and the A.A.M.M.C.A. plate counts per ml. of milk were 130,000 and 145,000 respectively. As previously pointed out, the 90 minute period of pasteurization may be considered a critical ordinate because at this time, the least amount of phosphatase is detected. It is therefore indicated that 100,000 to 140,000 thermophilic organisms by direct microscopic and plate counts have not produced at this period

an appreciable amount of the bacterial phosphatase. The 150 minute period shows an increase of the bacterial phosphatase from 0.02 to 0.08 units, which is the most rapid increase during the entire pasteurization process. The direct microscopic and plate counts show an increase from 100,000 to 3,200,000 organisms per ml. of milk. It is curious to note that a correlation of the direct microscopic and plate counts should occur at this period of pasteurization. This suggests further investigative work, for explanations as to the non-correlation, correlation, and again non-correlation of direct microscopic and plate counts as given on the 90, 150, and 210 minute periods of pasteurization. The 210 minute period shows a bacterial phosphatase production of 0.2 units and the direct microscopic of 39,000,000. The plate counts from O.S.N.A. and A.A.M.M.C.A. of 25,000,000 and 9,500,000 respectively were obtained per ml. of milk. The maximum direct microscopic count obtained was 150,000,000 organisms per ml. of milk at the 330 minute period. The maximum plate count obtained was 25,000,000 per ml. of milk from O.S.N.A. It should be pointed out that the size of the colonies on this medium were quite small, less than 0.5 mm. in diameter, while those observed on the A.A.M.M.C.A. were 3 to 5 mm. in diameter as has previously been stated, and were easily counted.

The Role of Skim Milk

The rapidity of the growth of this bacillus in skim milk became significant when it was observed that low count skim milk inoculated gave a direct count of less than 30,000, but after incubation at 44° C. for 6 hours, counts well into the millions were obtained. Samples of skim milk from the dairy were therefore requested for the following reasons:

1. To ascertain if the thermophilic bacillus was present in the skim milk.

* The heart infusion agar counts are not discussed as they were too low in numbers for correlation purposes.

2. Would the skim milk contain the bacillus in such numbers as to produce a false phosphatase test?

3. Was it obtained from route return whole pasteurized or from raw milk?

4. Was the skim milk being used in other milk products and for standardization?

Two samples of skim milk were received. They were divided into two equal parts. One set of samples was examined immediately for bacteriological counts and phosphatase tests. The other set was incubated at 52° C. for 19 hours and the examinations repeated. The results obtained are given in Table 3.

standardizing the butter fat content may explain the marked difficulty of ridding some dairies of thermoduric or thermophilic bacteria.

CONCLUSIONS

1. A false positive phosphatase test was obtained from properly pasteurized commercial bottled milk. The bacterial phosphatase was produced by a thermophilic organism. This organism has been isolated from the products of four Baltimore dairies.

2. The morphological, biochemical, and cultural reactions of this organism indicate that it belongs to the genus *Lactobacillus*. The name *Lactobacillus enzymotherophilus* has been suggested.

TABLE 3

Skim Milk as Received

Sample Number	Direct Count per ml.	Standard Plate Count per ml. at 37° C. 24 hrs.	Phosphatase Test Gilcreas Units
1.	180,000 many bacilli present	760	0.025 negative
2.	600,000 many bacilli present	290	0.03 negative
<i>Skim Milk after 19 Hours at 52° C.</i>			
1.	6,000,000 many bacilli present	Not made	0.20 positive
2.	6,500,000 many bacilli present	Not made	0.15 positive

The direct microscopic count and the phosphatase test would indicate that the thermophilic bacillus was present in the skim milk and that it had been pasteurized. The skim milk when incubated for 19 hours at 52° C. produced sufficient organisms to give false positive phosphatase tests, and repasteurization of the samples in the laboratory did not destroy the phosphatase enzyme. This suggests that the skim milk was obtained by separating route returned bottled pasteurized milk, which was confirmed by the Health Department inspector and the dairy plant proprietor. It would seem logical to expect that the continuation of this practice would act as a continuous inoculum and result in a marked increase of these organisms in the bottled product. The simple practice of continued reinoculation of raw milk with skim milk obtained from route returned pasteurized milk for

3. The bacterial phosphatase was extracted from the organism with distilled water. A phosphatase test of 0.20 Gilcreas units from 0.5 ml. of the fluid was obtained by washing approximately 50 million organisms in 10 ml. of distilled water. This bacterial enzyme was destroyed after exposure to 185° F. for 1 minute.

4. Production of the bacterial phosphatase in milk at pasteurizing temperatures of 142° to 144° F. begins after a 90 minute holding period. Two hours after the start of the enzyme production at 142° F. a phosphatase test of 0.20 Gilcreas units was obtained. At the 144° F. temperature a lag in the enzyme production is noted for 180 minutes, and the production thereafter is rapid.

5. The factors governing the production of the bacterial phosphatase are the inoculum number, the temperature and the time period. In one pasteurizing trial at 142°-143° F. for 150 minutes the direct microscopic, Old Nutrient Standard agar, and the American Association of Medical Milk Commission agar counts correlate to give approximately 3,200,000 bacteria per ml., and a phosphatase test of 0.03 Gilcreas units per 0.5 ml. of milk was obtained. The maximum direct micro-

scopic count of 150 million organisms per ml. of milk was obtained after 5½ hours of pasteurizing milk at 142°–143° F. and the phosphatase test gave 0.25 Gilcreas units per 0.5 ml. of milk.

6. It is an established fact that skim milk is an excellent culture medium. The rapid growth of this organism in skim milk and other media at favorable temperatures, 112° to 126° F., is readily observed within 1½ hours *in vitro* from rapid transfers. It has been shown that skim milk obtained from a dairy plant and used for standardizing, produced a false positive phosphatase test when the thermophilic organisms were in sufficient numbers. Raw milk heated for separating may be a contributing factor for promoting the growth of this and other thermophils. The practice of separating route return pasteurized milk for standardizing with thermoduric or thermophilic organisms present may be considered as a continuous reinoculation process. This practice may explain many positive phosphatase tests attributed to manual and mechanical defects in the dairy plant, when actually the false positive phosphatase test has been produced by a bacterial phosphatase enzyme from a thermophilic organism.

COMMENT

In studying the so-called "phosphatase test" as a control procedure for pasteurized milk, it has been learned that the milk phosphatase in raw or improperly pasteurized milk is a different substance from bacterial and other phosphatases that may be present in properly pasteurized milk where there has been a growth of non-pathogenic thermophilic organisms. Care is therefore necessary in distinguishing among the phosphatases where the phosphatase

test is used in milk control work and where a false positive test due to a bacterial phosphatase may lead to a misinterpretation of the laboratory findings.

ACKNOWLEDGMENT—The author is indebted to Huntington Williams, M.D., Commissioner of Health of Baltimore, for his valuable suggestions, to C. L. Ewing, Director of the Bureau of Laboratories, for assistance in this work, and in particular to Emanuel Kaplan, Sc.D., Chief, Division of Chemistry, who performed the phosphatase tests; Katherine Welsh, Anne Burkhard, and Margaret West of the Food Laboratory for their technical assistance in this work.

A Method for Determining the Number of Beds Required for Convalescent Care of Rheumatic Infections

BERNICE G. WEDUM, M.D., AND ARNOLD G. WEDUM, M.D.

*Department of Bacteriology, College of Medicine, University of Cincinnati,
and the Cincinnati General Hospital, Cincinnati, Ohio*

PROLONGED convalescent care for those recovering from rheumatic episodes is proving itself the best method available for combating that most serious manifestation of the rheumatic syndrome—rheumatic heart disease.¹ Provision of adequate convalescent facilities in London has apparently resulted in a reduction of the incidence of organic acquired heart disease from 2.0 per cent in 1926 to 0.8 per cent in 1936.² An increasing awareness of the need for facilities and for organization of convalescent care similar to that in England is manifest in this country.³

In view of the prospect that public health organizations will become aroused to plan for similar care of our rheumatic population, there is need for a method to estimate how many beds would be necessary in given communities in different parts of the United States. In England, when the London Rheumatism Scheme was organized in 1926, there was no clear idea of the exact number of beds required, but it was judged that an average of 6 months' care should be provided for every child with rheumatic infection. Facilities were slowly expanded until that ideal was reached. It was found that 1 bed per 550* elementary school children permitted ade-

quate convalescent care to be given rheumatic infections in that age group.^{3a, 5} Another estimate was 6 to 8 beds for school children per 100,000 total population.⁶ This latter method is a combination of American and British ideas. The British component was based on the assumption of 1 year's convalescent care during a 25 year duration of rheumatic infection with a known mortality of 149 persons per 100,000 in England and Wales.⁷ Thus 6 beds in 25 years would provide for 150 patients.

Both ratios have been used recently in the United States to estimate needs for convalescent care in two of our largest cities; the 1:550 ratio by Swift^{3a} in New York City, and the 6 to 8 per 100,000 ratio by Hedley⁸ in Philadelphia. These methods yield very divergent estimates. The former method calls for a far larger number of beds than does the latter. Furthermore it is obvious that any method of estimating beds based on school population, total population, or mortality cannot be applied throughout the United States because of well known regional differences in incidence⁹ and mortality¹⁰ of rheumatic infections.

The alternative method of starting on a small scale and expanding facilities slowly to meet the demand, as suggested by Huse,¹¹ is safe and apparently eco-

* An earlier estimate was 1.7 beds per 1,000 children.⁴

nomical, but it deprives many persons of needed care during the period of expansion. If convalescent care is as beneficial as we hope it is, such a procedure may not be economical in the long run.

How then is the necessary number of convalescent beds to be estimated in various localities of this country, if the ratios derived in England cannot be applied? We believe this can be done by using a 1:2 ratio, namely, 1 bed for every 2 rheumatic cases hospitalized annually in the community.

THE SITUATION WHICH PERMITS EVOLVEMENT OF THIS 1:2 RATIO

Cincinnati is unusual in that there is adequate convalescent care available for white rheumatic children aged 2 to 12. This care is provided by the Children's Convalescent Home of Cincinnati which was opened in 1931 to provide convalescent care for cardiac, orthopedic, post-operative, post-communicable disease and malnutrition cases.¹² Children are admitted from hospitals, clinics, and all child welfare agencies in the city and Hamilton County. It is supported by funds from the Community Chest and admits white children of both sexes from 2 to 12 years of age, inclusive. There are a few children 13 to 15 years old. No facilities are provided for the care of colored children. This institution has 100 beds, with an average daily census of 80.

During 1931-1940 there was a total of 2,614 admissions to the Children's Convalescent Home for all causes, of which 13 per cent were for rheumatic conditions. At no time were the facilities strained, and it can be said that all white children aged 2 to 12 who required care for a rheumatic condition were in a position to receive it. This applies particularly to children of the poorer classes. Some children, of course, did not receive this care when they needed it because of unwillingness

of parents to place them in an institution. Others may not have received it because some physicians are unaware of the benefits of convalescent care. However, these factors operate in every community, and we believe that facilities for care of this particular age and racial group are quite adequate in Cincinnati. The proportion of the rheumatic burden borne by this institution is indicated by the fact that 56 per cent of all patient-days for rheumatic admissions in all Cincinnati hospitals during 1930-1940 were spent at Children's Convalescent Home.

PROCEDURE IN OBTAINING THE 1:2 RATIO

The authors have recently completed a survey of all hospital admissions for rheumatic infections in Cincinnati for the 11 year period 1930-1940.* During this time 515 white patients under 13 were admitted with rheumatic infections to all Cincinnati hospitals, or 47 per year. In the 10 years (1931-1940) of operation of Children's Convalescent Home, 268 white children under 13 were admitted to that institution with rheumatic infections. On each admission, the average stay was 233 days. Including readmissions, during these 10 years each child was in the home 286 days, or a grand total of 76,763 patient-days. When this total is divided by 365 days, the quotient is 210. This means that 210 beds, or 21 beds per year, were constantly occupied by patients convalescing from rheumatic episodes. To keep an average of 21 beds per year in constant use, about 24 available beds (88 per cent occupancy) would be required. Thus, over a 10 year period, 24 beds per year at Children's Convalescent Home were needed in relation to the 47 cases among white children under 13 admitted

* *Rheumatic Heart Disease, Rheumatic Fever, and Chorea.* To be published.

annually to Cincinnati hospitals. Therefore, to provide adequate convalescent care, 1 bed for convalescents should be available for every 2 hospital cases of rheumatic infection per year.

It should be recalled at this point that, when the Rheumatism Scheme was organized in London, the preliminary estimate was an average of 6 months' care for each rheumatic child. Here in Cincinnati where no preliminary estimate was made, but convalescent care provided freely as needed, the same ratio emerges from 10 years of experience, i.e., 1 bed for every 2 cases, or, in other words, an average of 6 months' care for each case. Actually, not every case comes in for care, and some stay less than 6 months and some more. In Children's Convalescent Home every rheumatic admission averaged 8 months.

This compares favorably with the average care given in other localities—8 months in Boston,¹³ and 8.3 months in New York.^{1c}

APPLICATION OF THE 1:2 RATIO

Thus, if a community were contemplating provision of convalescent care for its rheumatic children, a survey over a 2 to 3 year period should be made of cases admitted for rheumatic conditions to hospitals of that community. If any considerable number of patients were admitted to more than one hospital, such duplications should be eliminated. The average number of cases admitted per year in the age group for which care is contemplated should be obtained, and 1 bed provided for every 2 cases.

For example, in Philadelphia there

TABLE 1
Estimate of Convalescent Needs by Three Methods

City	1:2 Ratio		1:550 Children		7 per 100,000

i. For the metropolitan district
j. Hamilton County, served by Cincinnati hospitals
k. An undetermined number outside of Cincinnati proper, but in Hamilton County

was an average of 383 cases of both white and colored children under 15 with rheumatic conditions admitted to hospitals per year over a 5 year period.⁸ To provide convalescent care for Philadelphia's rheumatic children under 15 alone would require 192 beds.

Examples of difficulties that arise when the English ratios are applied to American communities may be seen in Table 1. In Cincinnati the ratio of 1 bed for 550 elementary school children would provide Cincinnati with 108 beds, not the 33 which we know would be ample for both races under 15 years in an average year. Use of the ratio of 7 beds per 100,000 population would give Cincinnati 32 beds if the population of the city alone were used, but 44 if the population of Hamilton County were considered.

In Philadelphia the 1:550 ratio would provide 555 beds. Hedley made his estimate on the basis of the ratio 6 to 8 per 100,000 population and obtained 200 beds. The 1:2 ratio estimates 192 beds, in good agreement with Hedley's figure.

However, in New York City, Swift made his estimate with the 1:550 ratio and obtained 1,760 beds. A calculation based on 7 beds per 100,000 population, as used by Hedley, yields only 522 beds. Our estimate based on the 1:2 ratio is 1,558 beds, which is reasonably close to Swift's figure.

The 1:2 ratio is the one method which consistently approaches the estimates of Swift and Hedley. Yet if each had used the other's method of estimation the results would have been different. Actually each author used the method which worked best for the city under consideration.

The experience in London further verifies the applicability of the 1:2 ratio. In 1926, during the early stages of organization of the London Rheumatism Scheme, there was an estimate of 2,033 children⁴ admitted annually to

London hospitals with rheumatic infections. By 1936, 1,100 convalescent beds had been provided.⁶ This is essentially 1 convalescent bed in 1936 for every 2 cases hospitalized in 1926.

DISCUSSION

It should be emphasized that convalescent facilities in Cincinnati are adequate only for the limited group under consideration; white children aged 2 to 12. The only other institution in the city which has significant convalescent facilities is the Hamilton County Chronic Disease Hospital. Although designed to care for the indigent aged, it also serves for a few cases as a place for convalescence for white patients over the age of 12 and for Negroes convalescing from rheumatic infections. However, these facilities are unsuitable and inadequate. There is an acute need in Cincinnati for convalescent beds for Negro children and for all young adults. We estimate the number of beds necessary for Negro children as 6. The convalescent needs of young adults will be discussed in a future publication.

Before applying the 1:2 ratio, a community survey of hospital cases of rheumatic infections is necessary. Some may object to the expense incurred by a survey. In reply it can be pointed out that the cost of a convalescent institution may be as high as \$4,000 per bed.²

Communities using the 1:2 ratio would be unlikely to provide too many beds but might provide too few. This would happen if most acute episodes of rheumatic infection were treated in the home rather than in a hospital. It could also occur if, after a survey had been made, an increasing awareness of the seriousness of rheumatic infections caused more cases to be recognized and hospitalized.

It is important to realize that the adequacy of recognition of rheumatic infections in Cincinnati has little to do

with the validity of the 1:2 ratio. Since available facilities at Children's Convalescent Home have never been saturated, any increased number of rheumatic cases admitted to hospitals would simply have been reflected by increased admissions to the home, in the same 1:2 ratio as at present.

SUMMARY

There is an increasing awareness in the United States of the value of convalescent care for rheumatic infections, and of the lack of such facilities in this country. A method is needed to determine the number of beds required for convalescent care in a given community. Over a 10 year period the facilities for the care of rheumatic white children aged 2 to 12 have never been saturated at the Cincinnati Children's Convalescent Home. A survey of admissions to all Cincinnati hospitals has revealed the total number of these children, and the total patient-days spent by them at Convalescent Home. Based on this experience it has been found that 1 convalescent bed was required for every 2 cases admitted to Cincinnati hospitals. It is suggested that this 1:2 ratio be considered by communities intending to expand their facilities for care of convalescent rheumatic children.

Some Epidemiological Aspects of Tooth Decay*

BION R. EAST, D.D.S.

*Assistant Professor of Public Health Practice, DeLamar Institute of Public Health,
College of Physicians and Surgeons, Columbia University,
New York, N. Y.*

EXPERIENCE in the present war and in those of the past, together with related incidental data, offer opportunity to examine, on a geographic basis, certain epidemiological aspects of tooth decay. From an etiological standpoint, knowledge as to this disability is about on a par with speculations in the early part of the century as to the etiology of pellagra or knowledge as to the causation of malaria before Laveran's work in 1880.

Generally speaking, there are two schools of thought regarding the etiology of tooth decay. The first group considers the oral environment the sole determining factor, while the second group considers that the metabolic processes of the body influence the resistance of the teeth to the force or forces which cause decay. Whatever the merits of these or other hypotheses, they have no bearing on the present discussion.

The data herein presented for consideration consist of: (1) the rejection rates for "defective and deficient" teeth among the men in the draft for the United States Army in 1918; (2) exemption rates for "loss of teeth" among men drafted for the Federal Army in 1863-1864; (3) rates of past and present decay attacked teeth among

U. S. Naval recruits in 1934, and surveys of tooth decay among United States school children.^{4, 5, 6}

In this paper tooth decay includes past as well as present evidence of caries attack. It is realized that diseases other than tooth decay may contribute to the condition later referred to as "defective and deficient" teeth, or "missing" teeth, yet it is believed that among the age groups under consideration the effects of such diseases on the magnitude of the rates would be so relatively minor that they may be disregarded.

DENTAL REJECTION RATES AMONG DRAFTEES OF 1918

During World War I, the physical condition described as "defective and deficient" teeth caused the rejection of significant numbers of men called up for military service from the various states. There were two drafts during that war. The first was in 1917, the second in 1918. Only the data of the 1918 draft are considered in this discussion. This draft has been referred to as that of the "second million." The 1918 mean rejection rate for the entire country for "defective and deficient" teeth was 24.2 per 1,000 men examined at the army camps.

The examinations were made subsequent to May, 1918. This indicates that most of the examiners at the army

* Read before the Epidemiology Section of the American Public Health Association at the Seventy-Fifth Annual Meeting in St. Louis, Mo., October 30, 1942.

camps and the local boards probably had had a year or more to become familiar with the criteria and examining technics. Therefore, it does not seem unreasonable to assume that considerable uniformity would prevail, resulting in state rates, the magnitude of which may be properly compared one with another.

However, the states varied in the magnitude of their respective rejection rates. The Vermont rate was 102.85, while that of Arkansas was 2.90 per 1,000 men examined. The highest rates were among 5 New England states. The remaining state of that geographical group was 8th in rank among the 48 states and the District of Columbia. The mean rate for the New England states, as a group, was 76.15. The lowest rates were consistently among the southern and southwestern states. For example, the group composed of Arkansas, Texas, and New Mexico had a mean rate of 4.66 per 1,000 men examined.*

Unfortunately, the rejection rates for "defective and deficient" teeth at the local boards of 1918 are not available. However, when the rejection rates at the local boards for *all* types of physical defects are examined, it is found that the states with the high rates had, as a rule, high rejection rates for "defective and deficient" teeth at the army camps. This point seems important when comparing the magnitude of the several states' army camp rejection rates, because it helps to eliminate the possibility that the variations resulted entirely from careless screening at the source. The degree of correlation be-

tween high rejection rates for all types of physical defects at the local boards of the 48 states and the District of Columbia and high rejection rates for "defective and deficient" teeth at the army camps during the 1918 draft was determined by the correlation coefficient of Pearson. A value of $+ .63 \pm .09$ was obtained. This is a further indication that on the average the higher the rejection rate at the local boards for all types of physical defects, the higher was the rejection rate for dental defects at the army camps. The rejection rates at the army camps and at the local boards among the various states and the District of Columbia are given in Table 1. The rates for the 48 states and the District of Columbia are shown graphically in Figures I and II.

* Several preliminary statistical reports of dental findings among draftees of the several states during 1940-1942 suggest that the New England states will again have the highest rejection rates at both the local boards and at the Army Induction Centers for dental defects, and that the southern and southwestern states will have the lowest rates; however, it is believed that the available data are too meager to permit a final conclusion to be drawn in this respect at the present time.

TABLE 1

*Rejection Rates for "Defective and Deficient" Teeth among Draftees of Various States at Army Camps and for All Types of Physical Defects at Local Boards During 1918 (A);

DENTAL DEFECTS AMONG DRAFTEES OF THE FEDERAL ARMY IN 1863-1864

Dental defects also contributed to physical unfitness among the men of military age during the Civil War period. During that war there were two drafts for the Northern Army. In the draft of 1863 "loss of teeth" caused the rejection of 20.49 per 1,000 men examined. The 1864 rate was 25.37 per 1,000 men examined. As noted in the 1918 draft, the various states also differed in the magnitude of their rejection rates during 1863 and 1864. The New England mean rate for the 1863 and 1864 drafts was 23.07, while that of Delaware and Maryland was 12.09 per 1,000 examined men.

The mean rates for the Northern states contributing to the drafts of 1863 and 1864 are included in Table 1.

The states that contributed to both the 1863-1864 and 1918 drafts have been grouped into arbitrary but more or less natural geographical areas and their mean rejection rates for the two periods are shown in Figure III. It would be improper to use the "magni-

tude of the rates of 1863-1864 and 1918 as a measure of the relative severity or extent of the dental disease or diseases which caused rejection during the two periods, because the criteria differed. But, it may be observed with interest and possible profit that the magnitude of the rates for the same areas assume nearly the same relative position in both series. This duplication of events after a period of half a century is striking indeed.

TOOTH DECAY AMONG UNITED STATES NAVAL RECRUITS OF 1934

As previously pointed out, it is well known that the particular dental disease which contributed most to the dental condition in the draftees described as "defective and deficient" teeth in 1918 or "loss of teeth" in 1863-1864 was tooth decay. It is, therefore, pertinent to investigate the distribution of that disease throughout other groups of the population. Does the prevalence rate vary from state to state, from group to group living in different environments? Corroborative evidence which tends to substantiate this is found in a survey among a group of men who were enlisted in the United States Navy during the

year 1934. While the men in that naval group and the condition of their teeth differed from the rejected draftees, inasmuch as they were found suitable for military service, yet the method used in determining their dental status allows an estimate of the relative prevalence of caries, past and present, among the teeth of men of the various states. In the naval survey under consideration there were 4,602 white men. After enlistment they were assembled at Norfolk, Va., where they were examined by the same dentist* and their present and past tooth decay experience was recorded according to the number of decayed, missing or filled (DMF) teeth. On subsequent study by the naval investigator it was found that, as

a rule, the men of the northern states had more evidence of tooth decay, past and present, than did men from the southern states. The state with the highest rate, 12.54 decayed, missing, or filled (DMF) teeth per man was Connecticut—a New England state. Arkansas, the state with the lowest rejection rate for “defective and deficient” teeth at the army camps in the draft of 1918, likewise had the lowest decayed, missing, or filled (DMF) rate among these naval recruits of 1934. The New England states, as a group, had the highest rate in the entire series, 11.48; while Arkansas, Louisiana, and Mississippi, as a group, had a mean rate of 3.5 DMF teeth per man. The consistency with which these naval data tend to agree with the dental findings collected among men of the several states

at different times over a period of some 70 years seems to allow greater weight to be given them as being representative of the universe from which they were drawn than would ordinarily be the case where the numbers in the samples are relatively small. The rates for the several states and the District of Columbia are shown in Table 2 and Figure IV.

forces which tended to operate to produce dental diseases, particularly tooth decay, were not haphazard but more or less constant over a considerable period.

Most of the lesions of tooth decay which eventually caused the rejection of men in the several drafts or which caused the men in the naval group to have decayed, missing, or filled (DMF) teeth, had their inception when the individuals were relatively young, when their permanent teeth had been erupted a relatively short period. Therefore, as complementary to a study of the extent of dental defects among men of military age, it seems desirable to examine data as to permanent teeth of children in various parts of the United States.

Several dental surveys among children have demonstrated the geographical distribution of tooth decay. Mitchell⁷ found that the white children of Puerto Rico had less tooth decay than did children of the same age and color in the United States. Moore⁸ contrasted the dental condition of 393 preschool children in San Diego, Calif., with 550 children of the same age in Portland, Ore. He reported that 54.5 per cent of the San Diego children were without dental caries experience, while among the Portland children 22.5 per cent were without past or present tooth decay. In an extensive survey by private dentists coöperating with the U. S. Public Health Service during 1933-1934, the dental findings among some 1,500,000 school children are reported.⁹ It was found that the dental caries prevalence rates of the permanent teeth of children residing in different states varied greatly in their magnitude. For example, it was found that the mean number of permanent teeth attacked by decay among boys aged 13 residing in cities having a population of 100,000 or over of the states of Florida, Virginia, and Massachusetts was 3.09, 3.17, and 5.69 respectively. In Table 3 the mean

The Pearsonian correlation coefficient was used to determine the degree of relationship between high rejection rates at the army camps for "defective and deficient" teeth among the draftees of 1918 and high DMF rates among the naval recruits of 1934. The rates that were based on grouping the men of two or more states, as was done in the original report for 17 states, have been omitted from the calculations. The value of *r* was found to be $+ .70 \pm .09$.

This value indicates a relatively high and statistically significant correlation between high rejection rates for dental defects among the men of military age of 31 states in 1918 and high DMF rates among the young men of the same age 16 years later: that the force or

number of decayed, missing, or filled permanent teeth among Florida, Virginia, and Massachusetts city boys aged 7, 10, and 13 respectively is given, together with the number of children composing each sample.

(A) Messner, C. T., *et al.* Dental Survey of School Children, Ages 6-14 Years Made in 1933-1934 in Twenty-six States. *Pub. Health Bull.*, 226, 1936.

Because the surveys among children

which have just been referred to were made by groups of private practitioners, it has been suggested by some that differing criteria and methods of reporting might tend to vitiate them. Four other sets of data are presented which seem to be relatively free from such defects because the examinations were all made by members of the dental staff of the U. S. Public Health Service. This leads to the assumption that unusual uniformity would prevail in the data and that the relative magnitude of the different rates may be used as a reliable measure of the severity and extent of the disease among the different groups.

Two of these groups were whites who resided at Nicollet County, Minn., and Hagerstown, Md., respectively. The remaining two groups were Indian children who lived on reservations in northern and southwestern localities of the United States.

The decayed, missing, or filled rates among the permanent teeth for the various age groups of children are given in Table 4 and are shown, graphically, in Figure V. The values demonstrate

that, among these groups of children residing in different environments, the number of permanent teeth* attacked by caries at a given age differs, as do the rejection rates among the men of the Army drafts, and the DMF rates in the 1934 naval group. That is, the children who resided in the more northerly locations had greater evidence

they were children. In suggesting the probability of such a relationship; it is assumed that the distribution of corrective dental service would be at least as great among the population of the states with the high attack rates as among those enjoying the lower rates. While factors associated with latitude have been chosen to illustrate epidemio-

TABLE 4

Mean Number Decayed, Missing, or Filled (DMF) Permanent Teeth among 2,431 Nicollet County, Minnesota (A), and 4,416 Hagerstown, Md. (B), White Children; and among 1,149 Northern and 3,183 Southwestern Indian Children (C)

of past and present tooth decay than did those of more southerly areas. Among these groups of children the relationship between the number of attacked teeth and time approaches linearity, the curves only differing in their slope. This relationship persists in spite of the fact that the number of permanent teeth erupted, and therefore eligible for caries attack, increased from approximately 6 to 28 during the age periods studied. The data suggest that the relative dental fitness of the men of military age of the various states probably could have been predicted with considerable reliability from the relative condition of their teeth when

logical aspects of dental disease, it should be emphasized that other conditions and circumstances could and probably do influence and contribute to tooth decay. Dean,^{10, 11, 12} in his extensive investigations of the relationship between fluorine in communal water supplies and caries resistance, offers another illustration of the importance of introducing epidemiological methods when considering the phenomenon of tooth decay and its distribution among the population.

SUMMARY

Apparently there are marked differences in the distribution of dental diseases among groups of the population residing in various states of the United States. These differences are reflected in the magnitude of the rejection rates for dental defects among men who have been drafted for military service. When the rejection rates of the states contributing to more than one draft are listed according to magnitude, con-

*It has been assumed that the numbers of the various types of permanent teeth erupted at a given age would not differ among the children of the different localities. However, this is only a working hypothesis and has not been tested by extensive data. It has been found that no significant difference in this respect existed between the Hagerstown, Md., children and a similar age-sex group of Chicago, Ill., children. (Greenwald and East: Eruption Tables of Permanent Teeth of Chicago School Children. *Illinois Dent. J.*, Sept., 1941.)

siderable uniformity is observed in the resulting order of arrangement for each draft period. The possibility that these recurring phenomena can be explained entirely by chance and, or, by differing examining technics and criteria, is discussed and considered unlikely. Evidence tending to substantiate the probability that the observed differences are representative of the relative extent of the disease among the population of the respective states is offered by data resulting from the examination of naval recruits during 1934. The reasonableness of the hypothesis is further supported by data stemming from surveys of the extent of tooth decay among children residing in different geographical areas. The relationship between latitude and dental diseases, particularly tooth decay, has been used to illustrate some of the epidemiological aspects of the problem, but it is emphasized that many other known and unknown conditions and circumstances may, and undoubtedly do, influence the disease and its distribution. It is suggested that the study of dental diseases offers a particularly interesting and

profitable field for the use of epidemiological methods.

Syphilis Control in a State Prison

III. A Centralized Syphilis Control Program for the State Prisons of New York *

I. JAY BRIGHTMAN, M.D., MED.SC.D., AND
BERNARD I. KAPLAN, M.D.

*Consultant, Division of Syphilis Control, New York State Department of Health;
and Physician, Sing Sing Prison Hospital, Ossining, N. Y., and Acting
Director of Syphilis Control, Westchester County Department of Health*

IN previous communications^{1,2} we have described the marked improvement occurring in the care of syphilitic inmates at Sing Sing Prison following the inauguration of a specific program. As a result of the reevaluation of the status of each individual with syphilis there occurred a huge reduction in the number of inmates under treatment and a more adequate type of therapy for those who required it. We made the observation that imprisonment for an extended period might be interpreted, paradoxically, as a beneficial event in the life of a syphilitic, as it enabled him to receive a complete diagnostic appraisal and adequate therapy for his disease under conditions more suitable than those encountered by him in civilian life. In proof of this it was shown that, whereas only 13.5 per cent of those with a knowledge of the disease for 5 years or more had received adequate therapy prior to admission, 85 per cent of those requiring antisyphilitic treatment at the time of admission had fully completed that therapy 2 years later. In addition, we have indicated that the placement of a large number of syphilitic individuals under supervision for prolonged periods offers an

unusual opportunity for the investigation of problems referable to the course of syphilis and its treatment.

Because of the methods of reception and transfer of inmates within the New York State penal system, the above program at Sing Sing Prison was not complete by itself. Sing Sing Prison is a "receiving" institution and admits about 70 per cent of the total number of prisoners entering the state penal system. A number of these inmates are transferred each month to other state institutions, namely Attica, Auburn, Clinton, Great Meadows, and Wallkill State Prisons. Attica Prison receives about 25 per cent of the total number of direct admissions, and Clinton Prison about 5 per cent. Auburn, Great Meadows, and Wallkill State Prisons are strictly "transfer" institutions and receive all of their inmates from other prisons. There are occasional transfers of inmates from one "transfer" prison to another for various reasons. Therefore, it is obvious that unless all the institutions operating within this system maintained the same standards, the benefits of a diagnostic appraisal and decision as to the need for therapy accorded to an individual with syphilis at one prison might be lost when the patient was transferred to another.

In view of the above, a centralized system was visualized whereby through

* From the Syphilis Control Office, New York State Department of Correction and the Department of Medicine, New York University College of Medicine.

the coöperation of the various state prisons the care and treatment of an individual with syphilis would be adequately determined upon his entrance into the state penal system and continued in effect despite transfers from one institution to another. Also, the favorable results obtained by the re-evaluation of the records at Sing Sing Prison suggested that a similar approach might be made to the problem of syphilis at other institutions of the New York State Department of Correction. By these procedures, not only would improved methods of diagnosis and treatment be extended to additional large groups of syphilitic inmates but the combination of their records with those of the Sing Sing Prison patients would form a huge reservoir of statistical data.

PRELIMINARY SURVEY

In November, 1941, a meeting was held with the chief physicians of the various state institutions to discuss the creation of a uniform syphilis control program for the New York State Department of Correction. In the following month a field survey of the several institutions was made to determine the extent of their facilities, their personnel, and their methods for the care of inmates with syphilis. In general the findings paralleled the situation existing at Sing Sing Prison prior to the latter's inauguration of its syphilis program. A summary of these findings follows:

1. Little attention was paid to an evaluation of the many factors relating to the disease in each inmate with syphilis.

2. Patients were treated in large groups under rule-of-thumb regimes. With one exception, treatment was given in interrupted courses with intervals as long as, or longer than, the course. The schedule differed at each institution.

3. Little attention was paid to previous therapy. Too much reliance was placed upon the results of the Wassermann reaction of the

blood in guiding treatment. In some institutions, patients were continued on therapy for 5 or 10 years as long as the serology was positive, whereas inadequately treated patients were taken off therapy because of a reversal of the serologic test.

4. Spinal fluid analyses were not obtained routinely on all inmates with syphilis, except in one institution.

5. Chest roentgenograms were not obtained on late cases of syphilis.

6. Methods for the periodic observation of patients with syphilis were inadequate.

7. No facilities were available for the administration of fever therapy for neurosyphilis.

8. The physicians-in-charge were eager to coöperate in a plan designed to provide effective and adequate treatment of their patients.

THE SYPHILIS CONTROL PROGRAM

With the field thus surveyed a Syphilis Control Program for the New York State Department of Correction was formulated and launched in January, 1942. The central focus was designated the Syphilis Control Office (S.C.O.), and was located at Sing Sing Prison because of the position of the latter as the chief reception depot and because of its adequate facilities for diagnostic procedures and for the administration of special therapeutic regimes.

The functioning of the Syphilis Control Office can be summarized as follows:

1. *Review of current cases*—Each prison physician sent to the S.C.O. a copy of the record of every syphilitic inmate in his institution. These records were complete in regard to history, physical examination, laboratory tests, and treatment. The charts were reviewed by the staff members of the S.C.O. and suggestions were made as to any further work-up or treatment which might be indicated. These suggestions were then forwarded to the prison physicians.

2. *Admission of new patients*—All inmates admitted to Sing Sing Prison are interviewed as to a history of syphilitic manifestations, positive serologic tests, or antiluetic therapy. All patients giving a positive history, or showing syphilitic manifestations, or upon whom positive serologic tests are obtained in the routine examinations, are admitted to the Sing Sing Prison Syphilis Clinic. Complete

history and physical examination are then performed. Attempts are made to confirm all positive histories of syphilitic manifestations and treatment by correspondence with the medical authorities who previously cared for the individuals. Laboratory work-up includes quantitative complement-fixation tests determined by the New York State Department of Health, Division of Laboratories, complete spinal fluid analyses, telerontgenograms of the chest and electrocardiograms. The S.C.O. then makes a decision as to the future course of the individual. In general, there are 3 groups of patients: (a) those who are to receive no further antisyphilitic therapy; (b) those who are to receive routine therapy consisting of continuous, alternating courses of a trivalent arsenical and bismuth; and (c) those who are to receive special forms of treatment such as fever and intensive methods of arsenotherapy. The individuals of the first two groups are then eligible for transfer to other institutions, but members of the third group are eligible for transfer only after the completion of the special forms of treatment.

The physician in charge of each of the other "receiving" institutions carries out investigations similar to those of the Syphilis Clinic at Sing Sing Prison. He makes a decision as to each inmate's future course. A copy of the chart is then submitted to the S.C.O. for its appraisal.

3. *Transfer of patients*—When an inmate with syphilis is transferred from Sing Sing Prison to a cooperating institution, the S.C.O. forwards copies of his records. The prison physician is requested to continue the courses specified for each individual. The necessary follow-up examinations are indicated. It is requested that no changes be made in the regime prescribed by the S.C.O. or other admitting office before such is brought to the attention of, and is approved by, the S.C.O. and corrections made on its own records.

Upon the transfer of an inmate with syphilis from one cooperating institution to another, the transferring institution sends to the S.C.O. a notification of that fact together with its completed case records. The S.C.O. then forwards to the receiving prison a copy of these records including its suggestions as to the future course of the individual.

4. *Rôle of the cooperating physicians*—The functions of the prison physicians are as follows:

- a. Performance of history and physical examination on admission and a repetition of the latter twice yearly.
- b. Administration of routine treatment.

c. Performance of serologic tests (titered by New York State Department of Health, Division of Laboratories) twice yearly and of lumbar punctures and chest roentgenograms where indicated.

d. Keeping of adequate records in uniformity with all cooperating institutions.

5. *Parole or discharge of inmates*—When an inmate with syphilis is to be discharged by expiration of his sentence, the cooperating institution sends to the S.C.O. one complete clinical record including final suggestions as to the future needs of the individual. When the patient is released on parole, a copy is also sent to the parole officer. If further therapy or follow-up is indicated, the parole officer assigns the patient to an appropriate clinic and supplies that clinic with the record.

6. *Consultation service*—At least twice yearly, a staff member of the S.C.O. visits each of the cooperating institutions for the purpose of discussing problems and consulting about difficult cases. Visits may be made more frequently should the occasion arise.

7. *Handling of neurosyphilitic inmates*—The majority of patients with syphilis of the central nervous system are diagnosed on admission to Sing Sing Prison by clinical means or by spinal fluid analysis and are kept at that institution so that especially indicated forms of treatment may be administered. When such therapy has been completed, these patients may be transferred to other institutions.

When inmates with central nervous system syphilis are admitted directly to other institutions, or are first discovered at other prisons, arrangements are made to have these individuals transferred to Sing Sing Prison because of the therapeutic facilities there available. Upon the completion of therapy, the patient may be re-transferred to the original institution for follow-up.

8. *Establishment of the Central File*—The Syphilis Control Office established a Central File to serve as a collective reservoir for all information related to inmates with syphilis within the cooperating institutions. This file was begun with the records which were submitted to the S.C.O. for appraisal in the original review of current cases. Records of newly admitted patients are added when the diagnostic procedures are completed and the therapeutic regimes outlined. The charts are kept current by the addition of related correspondence, progress reports by the cooperating physicians, and the notations of the S.C.O. consultant at the time of his periodic visit to the institutions. When an inmate leaves an institution, the prison physician

sends to the S.C.O. a report which includes all information not previously recorded in the Central File and a statement relative to the future course of that individual. When an inmate is transferred from one cooperating institution to another, this fact is noted on the file of both prisons.

PROGRESS

In the six months which have elapsed since the inauguration of the program, considerable progress has been made. Five other institutions of the New York State Department of Correction have joined with Sing Sing Prison in establishing uniform methods for the care of inmates with syphilis under the supervision of the Syphilis Control Office.

The records of 942 patients from these 5 institutions have been brought up-to-date by the prison physicians and reviewed by the S.C.O. staff, as had previously been done with the records of inmates with syphilis at Sing Sing Prison. Seventy-five patients have been seen in consultation during a visit of an S.C.O. staff member to these institutions. Many inmates with late syphilis are having chest roentgenograms and spinal fluid analyses for the first time. The application of definite criteria for the determination of the adequacy of previous therapy has resulted in a reduction in the percentage of patients under treatment from 72.5 per cent to 19.3 per cent. Fifteen cases of active neurosyphilis were found which were previously undiscovered or were being unsuccessfully treated by routine methods over long periods. These inmates have been transferred to Sing Sing Prison for fever therapy.

The Central File now contains records of 1,502 current cases of syphilis under the supervision of the Syphilis Control Office of the New York State Department of Correction. This number includes 560 cases at Sing Sing Prison plus those of the 5 cooperating institutions. The records in this file

are kept up-to-date through notifications by the prison physicians as to changes in regime, transfer, or discharge of any patient.

DISCUSSION

The Syphilis Control Program has been launched primarily to permit the several large institutions of the New York State Department of Correction to cooperate in maintaining uniform standards in the treatment of the syphilitic inmates under their control, thereby insuring effective and sufficient treatment. The advantages of incarceration for an extended period within a single institution in allowing for the administration of adequate antiluetic therapy has previously been demonstrated.² The Syphilis Control Program brings the same advantages to all syphilitic inmates within the state penal system, including those who for various administrative reasons are subjected to one or more transfers. The syphilitic inmate now has the advantage of an initial complete diagnostic appraisal by physicians particularly interested in syphilis, and consultation by these physicians as need arises. The proper handling of the syphilitic during his period of incarceration results in an individual with much more confidence regarding his future and also precludes him from being added to the problem of syphilis and its complications among the general public when he is released.

The pooling of scientifically collected facts concerning these many syphilitics in the Central File should create a reservoir which later will bring forth much information and fill many gaps concerning current knowledge of the disease. As the average period of incarceration within a state prison is 2 years, and many serve sentences for 10 years or more, while others return because of violation of parole or new offenses, the chances appear unusually good for obtaining long term observations upon

these individuals. With an active case load of 1,500, and approximately 500 added yearly, the number of cases followed for long periods should be sufficient to allow us to draw conclusions of statistical significance. It is hoped that with the passage of years, answers can be found to such questions as the indications for therapy in latent syphilis, the differences in final outcome between untreated, inadequately treated, and adequately treated patients, the differences between adequate treatment early and late in the course of the disease, and finally an evaluation of the newer intensive methods of therapy.

SUMMARY

1. A centralized program for the care of syphilitic inmates in the various New York State penal institutions has been described.

2. By means of such a program, all

syphilitic inmates can be assured of adequate therapy during their periods of incarceration.

3. The establishment of a central file with records of 1,500 active cases, many of whom will be followed over long periods of time, may eventually yield a considerable amount of useful information regarding the course of syphilis.

ACKNOWLEDGMENT—Dr. Abraham Kosseff, Dr. Frank E. Holcombe, Dr. Leaman H. Caswell, Dr. R. E. La Grange, and Dr. Ira Wickner, prison physicians of Attica, Auburn, Clinton, Great Meadows, and Wallkill State Prisons respectively, rendered full coöperation in the inauguration of the Syphilis Control Program.

Efficacy of Standard Purification Methods in Removing Poliomyelitis Virus from Water*

HARVE J. CARLSON, M.S.P.H., GERALD M. RIDENOUR, PH.D., AND CHARLES F. MCKHANN, M.D.

Department of Public Health Engineering, University of Michigan School of Public Health and the Department of Pediatrics and Communicable Diseases, University of Michigan Medical School, Ann Arbor, Mich.

THE presence of poliomyelitis virus in feces of persons ill with the disease was first demonstrated almost thirty years ago¹ and has been verified many times in the last few years.^{2, 3} The presence of poliomyelitis virus in feces indicated that sewage might become contaminated with the virus and the possibility arose that the virus might persist in sewage for a considerable period of time—hypotheses demonstrated recently by several workers to be facts.^{4, 5} The gastrointestinal portal of entry, long maintained by Toomey⁶ and recently substantiated by others,⁷ would suggest that any substance that contained active virus taken through the mouth might be a hazard to the individual. It is quite possible that water could become contaminated secondarily from sewage and the virus thus find its way back to the intestinal mucosa. The viability of poliomyelitis virus in sterile water stored in the dark has been found to be over 100 days,⁸ and it has further been shown that chlorination by present-day methods^{9, 10} is of little value in the destruction of the virus. These observations point further to the

potential hazard of water as a possible means of transmission of poliomyelitis virus, although water cannot be at present incriminated as a transmitter of the disease.¹¹

The studies here reported have been undertaken to see if methods commonly employed in water purification plants will remove poliomyelitis virus from water which has been artificially contaminated with it. The investigation of the effects of the chemical and physical methods used in water purification were approached under the following headings: Storage, Sedimentation, Sand Filtration, Hydrogen ion Range, Charcoal Adsorption, and Ultra-violet Irradiation.

METHODS

General—A neurotropic virus, apparently an adapted poliomyelitis strain pathogenic for mice, was used throughout the experiments. Inoculations were made intracerebrally in amounts of 0.03 ml., and were made immediately after the removal by aseptic procedure of samples of the materials under investigation. The virus dilution used was 1:500 unless otherwise stated. Control groups of mice were included for each phase of the study. The control groups

* This study was aided by a grant from the National Foundation for Infantile Paralysis, Inc.

received the virus in the same quantity and by the same route as the test animals. All mice were observed at least once daily for paralysis or other evidences of illness. Two strains of mice were used in the experiments: University Hospital Strain and Webster Strain of white Swiss mice. The animals used were 3 to 4 weeks of age. All groups were observed for a period of 30 to 40 days following the inoculations before the protocol was completed. To obtain the original virus suspension, mice paralyzed in two or more extremities were sacrificed and their cords and brains removed. These were ground up in refined silica and suspended in broth or saline. After centrifugation at moderate speed for 5 minutes, the supernatant was removed and used as the virus concentrate. This was a 1:5 suspension of brain and cord. A fraction of each stock lot was frozen and stored in dry ice in a deep freeze unit for later use.

Couglution and Sedimentation—Battery jars to which city water or raw untreated water was added were used for sedimentation tests. Lime and alum were added to city water to obtain the floc, while only alum was used in the raw water. By varying the amount of lime added, variations in pH of 6.3, 6.7, and 7.0 were obtained. In water purification plants, raw waters are treated at different pH's, and by using these three we tried to approximate the pH range in standard use. To samples of city water, 100, 120, and 140 p.p.m. of lime were added and 100 p.p.m. of alum. In the raw untreated water, only 100 p.p.m. of alum were used. Fuller's earth, 100 p.p.m., was added to some samples of city water to increase particulate matter to the point of turbidity.

After the chemicals were mixed into the water, the virus was added and the water containing the virus and chemicals was then slowly stirred for 20 to 30 min. The sedimentation jar was

then placed in a refrigerator for 2 to 3½ hrs. to allow the alum floc to settle. Refrigeration was found necessary, otherwise the air dissolved in the water tended to carry portions of the floc to the surface. After the settling period, samples were removed aseptically for injection into the animals. Twenty-four hour samples were also taken several times, as it was thought that minute invisible particles of floc might still be settling at the end of the shorter holding period.

Filtration—A model laboratory sand filter was made with a glass tube, 2½" in diameter and 4' in length. Ottawa filter sand, having an effective size of 0.508 and a uniformity coefficient of 1.24, was placed in the tube to a height of 30", the bottom of the tube being occluded by a carborundum block 1¼" in height, to supplant the gravel used in filtration beds. A constant flow apparatus was installed to furnish a constant head to the sand filter. The details of this apparatus are shown in Figure 1.

FIGURE 1—Model of the Laboratory Flow Sand Filter

With the constant head maintained over the sand filter, the virus suspension could be added to the top of the filter without any change taking place in rate of flow. Samples of filtered water were collected at varying intervals from the bottom of the filter. Virus suspension was added at the top of the sand filter, both with and without alum floc impregnated in the upper layers of sand.

The flow of water maintained through the sand filter was 144 ml. per minute, calculated on the basis of 125 m.g.d. per acre, which is standard water plant practice. This rate of flow could be maintained by regulating the petcocks between the filter and constant flow apparatus and those at the bottom of the filter. A further check on the speed of flow through the sand filter was obtained by adding fluorescein dye (1:1,250,000) at the same time the virus was added and beginning the collection of samples at the first appearance of the color in the filtered water.

Activated Charcoal—Activated charcoal (Cliffchar Activated Carbon-R. Fine, 30 Phenol Value, Dow Chemical Co.) was suspended in concentrations of 10, 25, and 50 p.p.m. in tap water and thoroughly mixed before the virus was added. The carbon-virus mixture was then slowly agitated for 20 to 30 min. and allowed to settle for approximately $3\frac{1}{2}$ hrs. After the settling period, samples of the supernatant were taken for injections into the test group of animals.

Storage—Virus suspension was added to 50 ml. samples of tap water in sterile bottles and stored at refrigerator temperature. Samples for injection into animals were removed from the stored water, to which virus had been added, at intervals varying from 1 hr. to 100 days.

Irradiation—Direct sunlight and irradiation from ultra-violet lamps (General Electric and Westinghouse tubes) were used as the sources of rays.

FIGURE 2—Methods of Exposing Virus Suspension to Ultra-violet Irradiation

Both Toomey¹² and Jungeblut¹³ have reported effectiveness of ultra-violet irradiation in the destruction of poliomyelitis virus. The methods employed in our studies were similar to those described by Toomey,¹² except that larger quantities of virus and greater depths of material were used, as well as greater distances from the source of radiation. Figure 2 is a diagrammatic sketch of the apparatus in relation to the source of light.

The virus suspension in 1:100 dilution was exposed in uncovered glass dishes to the source of irradiation. In one experiment the distance from the light was 9" and the depth of the suspension in the dishes was $\frac{5}{16}$ ". In another experiment the source of radiation was 3' from the virus suspension, which was $\frac{1}{2}$ " in depth. In a third experiment the distance was 12" and the virus suspension $2\frac{1}{2}$ " in depth. In tests of direct sunlight the virus suspension was $\frac{1}{2}$ " in depth. Samples were taken at 5, 10, 15, 25, and 30 min. intervals in the first experiment and at 5, 15, and 30 min. intervals in the later experiments.

Aeration—Air at room temperature

was allowed to bubble through a 1:100 virus suspension for 45 min. Samples for injection were taken at 30 and 45 min. In making these experiments 25 ml. of virus suspension were placed in a side-arm test tube to which a suction pump was attached. Room air was drawn to the bottom of the suspension through a tube so that all portions of the suspension were well agitated by the passage of air.

Hydrogen ion Range—Virus suspensions in 0.5 ml. amounts were added to 9.5 ml. of buffered solutions of a pH range from 4.0 to 8.5. All were placed in the refrigerator for 1 hr. and were then neutralized to a pH of 7.0 and samples were taken for injection.

The pH of each sample was determined colorimetrically and was checked in the Beckman pH Meter; the pH after addition of the virus suspension, compared with the pH of the buffered solution, is shown in Table 1.

RESULTS

General—The appearance of paralysis in one or more mice in a test group was taken as an indication that virus persisted in the water sample under investigation and was viewed as evidence that the method of water purification employed on the particular sample, when reduced to laboratory scale, was unsuccessful in removing completely or inactivating completely the mouse-adapted poliomyelitis virus. In many cases mice died without paralysis of the extremities being observed. These animals have been segregated in the tabu-

lation of results even though mice in a virus-injected group, dying after one or more of the group were paralyzed, might be counted as deaths from the virus infection, because respiratory paralysis may occur in such animals before the extremities become involved.

Coagulation and Sedimentation—Paralysis developed in one or more mice of each group that received virus suspension subjected to coagulation and sedimentation procedures. However, the percentage of animals developing paralysis was usually not as high as in the control groups of animals which received untreated virus of the same dilution.

Thus, alum flocculation and sedimentation appeared to cause a slight reduction of the total amount of virus in any suspension, the amount of reduction being apparently proportional to the amount of virus present.

In the results shown in Table 2, the groups of animals which had received water of different pH's were not separated but were included under their respective headings of turbid, clear, or raw water, as it was found that variations of pH as used in this experiment did not affect the results. Rather, to interpolate here the results of the larger experiment on the effect of pH, it was found that this neurotropic virus withstood a pH range of 3.5 to 8.0, as shown in the ability of the virus to produce disease in animals after exposure to such variations in reaction for periods of 1 hr., but with neutralization to pH 7.0 before inoculation.

As shown in Table 2, 132 mice received water (containing virus) that had been treated with lime and alum. Of these, 56 mice died after developing paralysis, 25 died without paralysis being observed, and 51 were alive at the end of the experiments. In the control group 48 mice were injected with virus suspended in water but not treated with lime and alum; 28 animals were ob-

served to have paralysis, 10 died without paralysis being observed, and 10 were alive at the end of the experiments. Of the control animals inoculated with the original virus suspension, 25 of 30 mice succumbed after developing paralysis, 4 died without paralysis, and 1 animal survived.

Filtration—The results of the sand filtration experiments are shown in Table 3. A sample was taken when fluorescein dye first appeared at the outlet of the filter and at 1 min. intervals thereafter until the disappearance of the color. Six mice were used for each sample taken and eight or nine samples were taken on each experiment.

When sand filtration alone was used, 29 of the 60 mice inoculated with the filtered water became paralyzed. Apparently alone, the sand filtration held back little of the virus. In a later experiment, large quantities of alum floc were allowed to impregnate the surface layers of the filter, reducing the rate of flow from 144 ml. per min. to 102 ml. per min., or to approximately 65 per cent of the standard rate of flow. The results of this experiment were quite at variance with those found in the earlier experiments where sand filtration alone or alum precipitation alone was used. Of 54 mice receiving virus in water thus filtered through a partially blocked

* Questionable paralysis with death in two days

sand filter, only 1 animal developed paralysis. In this one case the paralysis was less extensive than in most of the control mice. Control groups of mice injected with the original virus suspension and the diluted suspension came down with paralysis in numbers as in the previous experiment, confirming the fact that virus was present and active. That a rather large accumulation of alum floc on the filter was necessary to hold back the virus was shown in the next experiment in which alum floc, layered approximately $\frac{1}{8}$ " thick on the surface of the sand filter, failed to hold back the virus. Thirty mice were injected with water to which virus had been added before passage of the mixture through the filter so covered with a layer of alum floc. Of these, 50 per cent were observed to develop paralysis. The control groups of mice injected with the original and diluted virus suspensions gave higher percentages of takes.

When the filter sand was backwashed, large amounts of alum floc were released from this sand. This was an indication that the floc had penetrated into the sand bed.

Activated Charcoal—Attempts to remove virus from water by adsorption on activated charcoal in the concentrations tested (10, 25, and 50 p.p.m.) were partially successful. There seemed to be adsorption of the virus particles on the charcoal, as the numbers of mice which became paralyzed when inoculated with water so treated were less than those in the control groups inoculated with a similar virus suspension not exposed to charcoal.

The partial adsorption of the virus on charcoal was further demonstrated. The settled charcoal particles were injected intracerebrally into mice, and induced paralysis in a high percentage of animals, indicating that adsorption on higher concentrations of charcoal might be a means of concentrating the

virus sufficiently for detection from a suspension in which it was suspected of being present in high dilution.

Ultra-violet Irradiation—The results of our first experiment with ultra-violet irradiation in which the light distance was 9", the depth of the virus suspension $\frac{5}{16}$ ", the dilution 1:300, and 30 ml. the total suspension used were similar to results reported by Jungeblut¹¹ and Toomey.¹² One mouse became paralyzed in the group which received the virus exposed to ultra-violet light for 5 min. while in the groups inoculated with suspension exposed for 10, 15, and 25 min., no animals developed paralysis. The usual numbers of animals in the control groups injected with untreated virus suspension became paralyzed.

In further experiments the amount and depth of virus suspension and the distance from the light were varied. Thus, in one experiment 600 ml. of a 1:300 dilution of virus suspension $2\frac{1}{2}$ " in depth was exposed to ultra-violet light 9" from the source of the light. This was to determine the effect of light at greater depth of material. In another experiment 60 ml. of 1:300 dilution $\frac{1}{2}$ " in depth were exposed at the distance of 3' in indicate the effect on the virus of increased distance from the source of light. Samples were removed from the bottom of the virus suspension by syringe and needle, care being taken not to agitate the liquid during the period of exposure.

In each experiment specimens were taken at 5, 15, and 30 minutes. Two animals died without paralysis in the series where the virus suspension was $2\frac{1}{2}$ " deep. These animals were in the group where virus suspension was exposed for 15 min. to ultra-violet irradiation. The virus suspension exposed only 5 min. 3' from the source of radiation caused paralysis in one mouse. Thus, only 3 animals of the 36 used in irradiation experiments became paralyzed or died, while all but one of the

18 animals used in the control groups which received the untreated virus in 1:300 dilutions became paralyzed.

Direct summer sunlight did not, on the other hand, appear to have an equal effect on the virus. Some of the mice in each group of 6 inoculated with virus suspension, after exposure for 5, 15, or 30 min. to direct sunlight, succumbed with paralysis. As this virus suspension was exposed to direct sunlight in $\frac{1}{2}$ " depth, the results indicated a definitely superior effect of the ultra-violet irradiation from artificial sources.

Storage—Virus has remained viable stored in tap water at refrigerator temperature for as long as 100 days. Of 90 mice receiving the stored water containing the virus for this length of time, 38 were observed to develop paralysis. This includes two groups of 6 mice in which none became paralyzed, indicating that the virus had died in these two lots of water. In all other groups, 2 or more mice were observed to develop paralysis. In the control groups of mice, injected with the original and the diluted virus, all mice but 1 succumbed with paralysis, while in the water-control group not receiving virus but water alone, all animals remained alive.

Aeration—Aeration for 30 and 45 min. of a 1:100 dilution of virus in tap water had little apparent effect on the virus. All the mice in two groups inoculated with aerated water succumbed after developing paralysis.

NOTE: It is to be noted that this study on the efficacy of water plant operations on the removal of poliomyelitis virus from artificially and heavily contaminated water is in no way a quantitative measure of the effectiveness of these methods. Quantitative variations in technic and combinations of the methods of

control must be employed before definite conclusions may be drawn. In this report no attempt has been made to show the lack of effect of chlorination on poliomyelitis virus as others⁹ have shown that present chlorine residuals in drinking water are not sufficient to destroy virus.

SUMMARY

The methods of water purification commonly employed, namely coagulation and sedimentation, sand filtration, adsorption on activated charcoal, aeration, adjustment of pH and storage, have failed when tested individually to remove completely poliomyelitis virus from artificially heavily contaminated water. Results of this study indicate that ultra-violet irradiation from artificial sources has an effect on the destruction of the virus in water greater than that exerted by direct sunlight, and is more effective in inactivating or destroying virus suspended in water than any single purification method commonly utilized.

The Improvement of Local Housing Regulation Under the Law

An Exploration of Essential Principles*

THE NEED FOR REEXAMINATION OF HOUSING CONTROLS

Objectives of the Committee's Study—

The public health elements of housing have come increasingly to be recognized as essential parts of the housing problem. The world-wide movement for adequate shelter is justified primarily by the demand for living conditions which are compatible with physical and emotional health.

For generations the law has recognized the right of public health authorities to act for the improvement of housing conditions, and many health officers have made substantial contributions to the control of this problem through law enforcement. Accomplishments in this direction, however, have necessarily been limited. Families do not live in slums by preference or by chance. Except in rare instances, they live there because they are poor. The demolition of bad houses where there are no good ones at a rent which can be paid by the slum dweller, or the requirement of structural alterations which cannot be economically justified, may deteriorate rather than improve the total community situation.

With the development of government-assisted programs of slum clearance and low-rent housing, conditions have radically changed. Though such enterprises are now necessarily interrupted by the war, they must be resumed on a greater scale in connection with post-war plan-

ning for reemployment and reconstruction. As this occurs, it will be possible in increasing degree to proceed with the elimination of substandard dwellings. The hands of the health officer and of the fire and building inspector will be freed to accomplish results hitherto unattainable. Furthermore, rehabilitation and slum elimination carried out in cooperation with local housing authorities may be so organized as to contribute materially to sound and constructive community planning. In addition, it is essential that the clearance of slums and construction of new housing through public subsidy be supplemented by regulations that are adequate and enforced to prevent the development of more slums due to the absence of proper control over new residential construction.

The present codes and laws which deal with substandard dwellings are generally inadequate, and the machinery of administrative control wasteful and chaotic. There is a valuable opportunity at the present time to study rational and constructive approaches to the problems of legal control of substandard housing.

The Committee on the Hygiene of Housing has received numerous requests from local and state officials for advice on the drafting or revision of housing regulations; and the companion Committee on Housing of the Health Officers Section of the Association has recently been in correspondence with over forty health officers in regard to this and related problems. No adequate solution can be obtained by a scissors-and-paste adaptation of existing laws. The whole

* Report of the Subcommittee on Housing Regulation, of the Committee on the Hygiene of Housing, Committee on Research and Standards.

problem must be thoroughly studied from a fundamental viewpoint, with special reference to the powers which are delegated to the health officer for the framing of regulations.

The present memorandum is a preliminary exploration of this important field. Later releases of the committee are planned to review significant practical experience, both under the usual forms of housing regulation and under new types of laws and ordinances; and also to formulate, in so far as practicable, definite quantitative standards, specific administrative and enforcement provisions, and skeleton or model drafts of basic legal instruments.

It is obviously impossible to consider the housing responsibilities of health departments alone, for they interlock at many points with those of other agencies. In its first exploration of the problem, therefore, the committee conducted extensive correspondence with health, building, and housing officials throughout the United States, and with leading unofficial housing agencies, to canvass their opinion and experience as to the most feasible types of housing control.¹

Two viewpoints were outstanding in the replies received. First, that mere amendment of building codes as we now know them is not a practicable means of establishing the necessary standards for future housing construction, primarily because these codes are concerned mainly with the structural adequacy of buildings in general, and only to a minor degree with the healthfulness and livability of dwellings. The drafters of building codes, while prescribing, as they must, for a diversity of structure-types, have seldom attempted to cover the full range of essential housing standards which derive from broad considerations of healthfulness and well-being in the home. This conclusion in some form was the one most generally advanced in support of a new type of comprehensive

housing code, which should include at least the dwelling provisions of the building and related codes, but should cover a considerably wider range than these traditional documents.

The second striking feature of the correspondence was the wide agreement that public health officials should begin to assume real leadership and responsibility in developing control of conditions in existing dwellings, and that health department responsibility for occupied housing should be clearly recognized in any future type of housing regulation, whatever the division of responsibility for new construction. This does not mean that the health department must necessarily enforce such regulations in every community, but that when it does not itself enforce them it should accept its responsibility for seeing that they are enforced, to the point if necessary of insisting that it be given this power and authority.

These views have strongly influenced the committee, and they form the point of departure for the present memorandum. This first statement has also been influenced by the committee's critical study of the composite structure of state and local housing regulations in the State of Connecticut, made in coöperation with the new Housing Division of the Connecticut Department of Health, during which many elements of confusion and weakness in the typical pattern of housing regulation were clearly revealed.

Special attention will be given here to the regulation of existing housing, not only because of its basic significance to health departments and their possible future housing programs, but because of its peculiar importance during the war. Since the war is bringing virtual cessation of normal building as well as of the public housing program, it will necessarily prolong the use of substandard or marginal dwellings everywhere. In centers of war activity it is also increasing

the burden of overcrowding. In some such areas it is causing pressure for considerable increases in dwelling capacities by the conversion of large dwelling units into small ones. Regulatory powers must therefore be made effective both in order to conserve needed structures generally and to control special wartime problems of occupancy and alterations. Furthermore, in some localities the war is producing temporary housing that should be removed when the crisis ends, and local authority may be necessary to bring this about.

The Pattern of Housing Regulation—Adequate control of housing from the viewpoint of public health requires many forms of protection: the adoption and enforcement of health, safety, and amenity standards for new dwellings of both single- and multi-family types, including their environment; the development and enforcement of standards of maintenance and occupancy for existing family dwellings; the treatment of peculiar problems (both as to initial character and operation) of special dwelling facilities such as lodging houses, trailer camps, hotels, and dormitories; and the extension of suitable controls to the built-up areas beyond the corporate limits of cities so as to preclude the development or continuance there of slums. In addition, the protection of rural housing has received little attention. It presents a challenging problem that must receive careful study. It cannot be forever neglected.

The usual instruments for local housing regulation are of several types. The construction of new buildings is commonly governed by codes and ordinances forming part of the state or local organic law, enforced by building, zoning, and fire departments. The health status of the occupants of existing dwellings may be protected either by similar ordinances or by health department regulations having the force of law, but authority in the latter case is often limited to

certain classes of dwellings such as tenements and lodging houses; single- and two-family dwellings are commonly unregulated as to conditions of occupancy except where fire hazards or public nuisances are involved.

Among the traditional instruments for housing regulation the local building code is, generally speaking, the most elaborately developed. It is, however, largely restricted to new construction and, as previously noted, must cover many types of structures in addition to dwellings. Zoning ordinances deal with land coverage and segregation of alien uses from dwelling areas, but they do not affect existing structures. They are often weakened by their preoccupation with the problems of business areas and the preservation of single-family districts, or by indiscriminating grants of variance. Frequently their standards are too low to prevent congestion of buildings on the land. The maintenance of existing dwellings is sketchily dealt with—if at all—in building construction codes; health and fire department regulations may contain additional provisions on upkeep, services, and occupancy, but seldom are these regulations for existing dwellings either complete or conveniently accessible *in toto*. Exceptions do exist, but they are rare. The creation and operation of lodging houses, trailer camps, or other special dwelling types are often covered by special laws or ordinances, but here as in other fields of regulation the controls are likely to be based on models borrowed from other communities rather than upon discerning study of local problems. Suburban areas commonly have only partial controls. Rural districts usually lack them altogether, or may be saddled with statewide regulations which are meaningless in the absence of machinery for enforcement.

The composite effect of these various types of regulations that exist in most communities is anything but orderly or

clear, and the practical results of the confusion are extremely serious. Housing provisions may be generally unknown and unenforced, in part because they are lost in chaotic documents. Health, building, and fire departments may operate each in ignorance of the others' activities, if not in fact of their responsibilities. Inspection is divided and may be sporadic and wasteful of manpower. Broad powers, loosely worded, may hamper enforcement through the officials' fear of personal liability. In times of housing surplus unfit dwellings are not destroyed, as they might often be by the exercise of clearly existing powers; in times of shortage they may be occupied with no proper regulation in terms of special maintenance required. Both the layman and the courts are more likely than not to be ignorant as to what comprises existing housing regulation, and many an important test case may escape prosecution or be settled to the detriment of the community as the result of nothing more sinister than the prevalence of sheer confusion.

Numerous cities and several of the states, in an attempt to deal with these problems, have adopted housing codes which aim to provide more or less coordinated regulation. Four noteworthy types of controls developed in recent years will be analyzed in this and later studies of the committee:

1. General housing laws such as those of Michigan and Iowa (based on Lawrence Veiller's model housing law of 1920). These deal with both construction and upkeep of single- and multi-family dwellings, usually in cities above a certain size. Such laws may provide for incorporating the pertinent sections of the local building code, but they set forth additional requirements on such matters as sanitary facilities, required space, lighting, heating, and repair. Such acts may define the responsibility of building, health, and fire departments; in some states they authorize the

creation of a special housing-enforcement official. (Twelve states are known to have enacted housing statutes, but the majority of these are the old-line type of tenement-house regulation.)

2. Comprehensive local codes which incorporate the essential features of general housing laws (such as discussed in 1).

3. Special laws or ordinances, defining unsafe or substandard dwellings, and prescribing remedies through repair, abatement, closure, or demolition. These have been adopted in a number of states and cities, in an attempt to control the most flagrant conditions in existing dwellings.

4. Enabling acts which omit specific regulations but delegate the power of drafting these to a local officer or commission. This type of control is a recent and promising development which will be considered in some detail later in the present statement.

THE LEGAL BASIS OF HOUSING REGULATION

If broad and constructive results are to be attained, well defined powers must be placed in the hands of appropriate enforcing authorities. What shall be the basis of these powers?

General Limits of Protection — It seems clear, first of all, that the requirement of minimum conditions essential to health and safety should apply to all types of structures used for human habitation. It was natural that multiple dwellings and rooming houses should have received first attention in the development of housing control, since these buildings involve specific problems of manager-maintenance with regard to shared stairways and passages, common sanitary facilities, fire escapes, and the like. Yet regulation must not stop short at this point. There seems no valid reason—either legal or social—why the inhabitants of one-family and two-family houses should not also receive legal

protection, and it is a sign of progress that most of the regulations adopted in recent years have broader coverage than the earlier laws concerned primarily with tenements.

It is sometimes suggested that the regulation of housing should be limited to rented homes; but this distinction seems no more reasonable than one based on the size of the building concerned. The parent has no more vested right to prejudice the health and safety of his own children or his neighbors than the landlord has to work similar injustice on his tenants. The members of a family living in their own home should enjoy modern health protection under the law as much as the members of a family living in a rented dwelling. In some cities owned homes in certain low-grade areas are on the average more dangerous than rented homes. It would clearly be fantastic to clean up a block of rented homes leaving isolated owned dwellings in the same block in a hazardous and insanitary condition. It is recognized, of course, that in some communities psychological factors may restrict the degree to which owned homes can be regulated.

Another possible criterion for limiting the field of operation of a housing code is the size of the community or the density of population in the area concerned. From the standpoint of practical expediency it is obvious that the same standards cannot be enforced for isolated farm houses that are practicable for city tenements. There is even some logical ground for such a distinction, to the extent that dangers of conflagration and of epidemic disease constitute a greater hazard in crowded communities. The distinction is, however, one of degree rather than one of kind.

The committee is therefore of the opinion that within any given homogeneous area there should be substantially uniform legal requirement of appropriate basic essentials for health and safety in

all buildings used for human habitation, irrespective of types of buildings² or ownership.

Regulation of New Construction and of Existing Dwellings—Historically, in legislative enactments, the control of new building and that of existing houses has usually been kept separate, for two reasons. In the first place, regulations for new construction have commonly been—and must practically be—more rigorous than those for existing dwellings. In the second place, enforcement of the two types of regulations has usually been in different hands. The approval of plans and the inspection of construction have been conducted on established engineering principles by building and fire departments, while the problems of occupancy and maintenance have been dealt with largely by health and fire departments.

From the long-range standpoint of reasonably coördinated local housing policy, such a sharp separation of functions is perhaps unfortunate, but there is no simple universal remedy.

The committee believes that it may be desirable in the long run to combine or coördinate all types of housing regulation in a comprehensive housing code, but it recognizes serious obstacles to such a course in most communities. For immediate purposes, in most places it seems necessary to treat the regulation of new construction and of existing dwellings as separate problems. Although the present statement is chiefly concerned with the problem of existing housing, the committee plans in its future studies to consider and appraise the various possible means for increasing coördination of responsibility in these two fields.

It is believed that real and significant progress can be made in many communities in the immediate future by the following steps: (a) the formulation or revision by the local health department of regulations for existing dwellings, in

order to bring these controls into reasonable conformity with contemporary standards; (b) the compilation of those sections of the building, zoning, fire, or other ordinances and regulations which affect new dwelling construction, and the distribution of these provisions in convenient form not only to builders but to all interested official agencies, including the local health department; (c) a critical study, by official and citizen groups concerned with housing, of the coverage provided by the regulations cited in (a) and (b) above as a basis for developing such integration of housing control as may be locally desirable.

Direct Statutory Control vs. Rule Making under Delegated Authority—The next problem to be considered is whether the control of existing dwellings should be in the form of a detailed ordinance enacted by the regular legislative authority of the area or in the form of more flexible regulations promulgated by an expert body or official to whom the task has been delegated by proper legislation. Codes for new construction have generally been of the former type, while the problems of occupied housing—aside from fire department inspection—have been left largely to the local health department. This responsibility has perhaps been more honored in the breach than in the observance.

In connection with maintenance and occupancy standards in existing dwellings, the arguments for control under flexible administrative regulations are very strong. A considerable proportion of such dwellings will necessarily fall below any reasonable standard for new construction, either as a result of:

1. Factors in original construction which cannot be retroactively corrected; or
2. Insanitary, unhygienic, or hazardous conditions due to deterioration, defective maintenance, or improper occupancy.

In dealing with problems of this kind, the clear and specific formulation of detailed ordinances would seem to simplify

enforcement. On the other hand, any standards which can be immediately enforced in a given community will almost invariably fall far below the minima essential for health and safety. There is danger that such low standards, if embodied in ordinances or statutes, will become so crystallized as to halt further progress. A given city, for example, enacts a certain standard for the ratio between the number of dwelling units in a tenement and the number of toilets required. This may be the best ratio which it is possible to approach at the time of adoption. Within five years that standard may be so low as to prevent improvement toward a more desirable ideal which would otherwise be reasonably attainable. It is therefore particularly desirable to formulate standards for existing dwellings in such a way that they can be readily and promptly modified to make possible a maximum rate of progress.

In some communities there exist housing ordinances affecting existing structures that are effective and are enforced. They have been modified and improved from time to time, and have stood the test of courts and contain adequate regulations in specific form.

Even where good housing codes are administered by other agencies, the local health department must probably assume certain fundamental responsibilities with respect to occupied housing. Where there is no comprehensive regulation the health department has potential powers which may be called upon to meet the need. For the undertaking of such a task there is useful precedent in the historic and generally accepted rule-making powers of the health department. Local health departments in many states now have the power to formulate a sanitary code containing detailed requirements for realizing the broad general purposes of protecting the public health. Such a code of regulations has the advantage of being pre-

pared by public health experts and the even greater advantage that it can be readily and progressively amended to conform to changing needs and possibilities. It is not a question of formulating absolute standards of perfection, but of proceeding step by step from an unsatisfactory status toward an ideal as fast as expediency and public opinion may permit.

In communities where the rule-making power of the health department is broad and well established, this department, in coöperation with local building, zoning, and fire authorities as desirable, can proceed under its general powers to formulate regulations under which it may order such corrections as are essential for the protection of life and health, condemning such properties (after due notice and opportunity for public hearing) as cannot meet, or after a reasonable time have not met, the fundamental needs of health and safety.

Where such basic rule-making powers are not considered legally or psychologically adequate, a city ordinance or state law could be passed specifically authorizing the local department of health to formulate a body of regulations for preserving health and safety in all existing dwellings designed or utilized for human occupancy.

In Baltimore, for example, an ordinance of this type was added to the *City Code* in 1941.³ After certain general provisions fixing the responsibility for cleanliness on the occupant and the responsibility for repair on the owner or agent it is provided that

1. "Whenever any dwelling, or any building, structure, excavation, business pursuit, matter, condition or thing in or about a dwelling on the lot on which it is situated, or the plumbing, sewerage, drainage, light or ventilation thereof is found by the Commissioner of Health to be dangerous or detrimental to life or health, the Commissioner of Health may order that the matter, condition or thing be removed, abated, suspended, altered or otherwise improved, as his order shall specify."

2. "Whenever it shall be found by the Commissioner of Health that a dwelling is unfit for human habitation, or dangerous to life or health by reason of want of repair, of defects in the drainage, plumbing, lighting, ventilation or the construction of the same, or by reason of the existence on the premises of any condition likely to cause sickness or injury among the occupants of said dwelling, or for any other causes affecting the public health, the Commissioner of Health may issue an order requiring such dwelling to be vacated."

3. "The Commissioner of Health is hereby authorized and empowered to make and adopt such rules and regulations as he may deem proper and necessary for the enforcement of this ordinance for the better protection of the health of the city."

This type of ordinance, though its efficacy has not been fully tested, seems to offer a most valuable approach. Such broad delegation of powers may of course be challenged in litigation, and it will be of interest to follow suits which may arise under this or similar ordinances. There is, however, abundant court experience in public health cases to suggest that all reasonable exercise of these powers in good faith will be upheld. Such an enabling act may be adopted on either the state level or—if authorized by grant of power by the state—the local level. If it be a state law, the power to formulate specific regulations should preferably be delegated to local health authorities. A statewide body of regulations would necessarily have to be very general and either too weak for advanced urban areas or too severe for many rural areas. Furthermore, in rural areas the machinery for enforcement is generally lacking, and it is fundamentally unsound policy to promulgate regulation which cannot be enforced.

Whether housing regulations be in the form of statutory enactment or administrative regulations, it is obvious that their provisions should be correlated with those of local zoning ordinances.

In any case, when the sum of defects present in a dwelling is such as to con-

stitute a serious menace to the health or safety of the occupants and where such condition cannot be—or after a reasonable time has not been—corrected, the health officer should have power to forbid continuance of human occupancy or to order demolition.⁴

SPECIFIC OBJECTIVES AND CONTENT OF HOUSING REGULATIONS

If we accept the general principles of approach outlined above, the questions next arise: For existing dwellings, what conditions of use, occupancy, and maintenance should be set as prerequisites to continued habitation? With respect to new housing, what factors should the regulations cover as to site requirements, construction, interior layout, and equipment? The same factors must be considered, generally speaking, whether the controls take the form of a specific state housing law or local ordinance, or that of administrative regulations under an enabling act.

New Construction—While the committee is not here dealing primarily with either the administration or the detailed content of building codes or other controls for new construction, it has become clear in our studies thus far that the usual building code fails to provide certain safeguards which are essential from the viewpoint of health, safety, and amenity. Proper regulation of new construction is of such importance that it cannot be passed over lightly even in a statement dealing essentially with existing structures. We therefore call attention to the scope and some of the principal weaknesses of typical building codes, in order to bring these to the attention of public health officials or others who should be concerned with long-range improvement of housing regulations.

Certain of the health and safety regulations needed for new dwellings are well handled in the usual building code, and these are clearly outlined in recent

literature on building codes, including bulletins on code arrangement by the National Bureau of Standards and the American Standards Association.⁵ These model documents set forth factors of building construction, design, and equipment which should be controlled. The form of their recommendations approximates a statement of the fundamental objectives of regulation for each topic considered.

Building codes drawn according to these recognized models will cover such health, safety, and amenity factors in new housing as the following:

General building restrictions: construction safeguards within fire districts, restrictions as to building height with different types of construction, and similar factors.

Light and ventilation: number, area, and openability of windows; requirements for artificial lighting; and (perhaps rather obliquely under such a heading) the sizes of habitable rooms and the regulation of their occupancy.

Means of egress: number, types, and location of exits including fire escapes; width of stairways and exterior doors, etc.

Construction requirements: quality of construction and features of wall and floor design needed for structural safety.

Fire protection: standards for fire-resistiveness with various types of construction.

Chimneys and heating appliances: Standards of design and construction of heating installations are prescribed, but the proportion of rooms to be provided with heating facilities is commonly ignored, as are measures for the control of smoke.

Electrical and plumbing requirements: These are commonly handled by reference to separate codes. Such codes specify the quality of installation if it is made, but often do not require that basic facilities be actually provided.

It is urged that in future regulations for new housing construction these usual items of building code coverage be supplemented by regulations on at least the following subjects:

Site requirements: New dwelling construction should not be allowed (and building permits should not be issued) unless adequate water supply of good sanitary quality and adequate sewage disposal facilities exist, or

unless their development is shown to be feasible and is included in the construction scheme. Restrictions should be placed on the development of swampy or floodable lands, and there should be requirements for compliance with local subdivision regulations and conformity with master plan provisions for streets and roads.

Sanitary provisions: A new type of chapter should supplement the traditional plumbing code provisions on quality of materials and workmanship, setting definite minimum standards as to the number and types of sinks, toilets, and installed bathing facilities to be required in various types of dwellings. Running water, toilet, and bath or shower should be required in every urban dwelling unit. Cross-connections and back-siphonage should be clearly dealt with if they are not handled in a plumbing code.

Room sizes, layout, and space requirements: Code regulations in the future should seek to define room sizes in such a way as to permit the installation of necessary furnishings and allow for unimpeded circulation and the exercise of each room's basic functions under normal occupancy. Reasonable storage space should also be required.

Household equipment: In view of the "industrial hygiene" problems involved in the performance of some 60 person-hours of housework per week in the average home it would seem reasonable to set some standards of adequate facilities for cooking, laundering, and food preservation.

Vermin and insect protection: Appropriate provision should be made for rat-proofing, and for termite protection and mosquito-proofing in regions where these are necessary.

Other new types of chapters may be needed to deal with problems of miscellaneous mechanical equipment (installed refrigerators and such types of forced ventilation systems as may occur in multiple dwellings) and secondary buildings on the same plot with residential structures.

A most encouraging attempt to remedy some of the weaknesses of the usual building code is found in the federal Central Housing Committee's recent dwelling construction code recommended for war housing areas.⁶ This document appears to mark a distinct step forward in dealing with some of the customary shortcomings indicated above.

Little consideration has yet been given by the Committee on the Hygiene of

Housing to the usual coverage of zoning ordinances, but it is believed that if these were more carefully drawn with respect to standards of healthfulness in housing they might be made the instrument for some of the environmental regulations clearly needed but lying beyond the scope of construction codes. They should aim to avoid overzoning for industry and business, and to prevent too easy modification.

Existing Dwellings—For the control of existing dwellings there is much less systematic doctrine or practical experience than that available for new construction in building and related codes. Aside from the few states having general housing laws (some of which appear to cover matters of occupancy and maintenance with considerable skill) and the rare instances in which cities have housing codes or rather complete housing sections in building codes, control of occupied housing is usually carried under the broad nuisance powers or scattered specific provisions of sanitary codes or building codes.

The committee has not yet found any set of regulations for existing dwellings which can be taken as a wholly satisfactory model. During the Connecticut study previously cited, a tentative series of topics was therefore devised, under which the essential problems of structures in use may be analyzed. It is recognized that some of these categories may need to be combined or altered in the drafting of practical regulations. However, the listing of these topics, with illustrative statements under a few of them as to the purposes which should be served by specific regulations, will indicate the range of problems involved, and will reveal significant gaps in the usual type of occupancy regulations.

Occupancy and overcrowding: To prescribe minimum standards of space per family or per person (probably in terms of room units or floor area rather than cubic space, the

usual criterion) and to assign responsibility for determining the capacity of dwelling units⁷; to specify types of rooms (such as those without windows, those of seriously deficient size, privacy in circulation, shape, lighting, heating, etc.) which shall not be used for human occupancy; to define "person" for purposes of enforcement and to specify the ages at which separate sleeping rooms should be provided for children of opposite sex; to establish occupancy norms for special types of dwellings such as lodging houses, trailers, and dormitories, and norms for non-typical spaces (basements and attics with living quarters) in common types of structures; to deal with special occupancy problems in case of disease.

*Permitted uses, use-conversions and alterations*⁸: To limit the types of nonresidential use which may be introduced into dwelling structures or their immediate environment; to safeguard residential uses from hazard or nuisance connected with such nonresidential uses; to provide for needed physical separation between residential and hazardous non-residential uses in mixed structures; to assure the maintenance of structural soundness and safety in relation to use-changes involving alteration; to insure that suitable occupancy controls shall routinely be invoked in relation to changes of use; to control permitted changes in type of residential use (including space and sanitation requirements for conversion to light-housekeeping units).

Structural soundness and repair: To require maintenance of repair of all major elements of a dwelling as necessary to provide: (a) tightness to the weather; (b) reasonable possibilities of heating; (c) control of rat harborage; and (d) reasonable freedom from danger of bodily accidents or structural collapse. To provide for substantial compliance with standards for new construction in the event of major voluntary alteration or restoration.

*Provision and maintenance of sanitary fixtures*⁹:

Maintenance of utility supplies (water, electricity, gas) in safe operable condition

Heating, lighting and ventilation of habitable rooms

Lighting and cleaning of shared spaces such as public halls

Storage and disposal of garbage and other refuse

General sanitation and control of nuisances

Obstructions to egress; other specific fire hazards

Fire protection equipment

Control of rodents and insects

Safeguards for abandoned or unused dwellings or accessory structures.

These, or items like them, are the elements out of which it would seem a framework for clear and adequate housing regulation can be developed.

ADMINISTRATION AND ENFORCEMENT OF HOUSING REGULATIONS

Whether the fundamental housing standards are formulated in an ordinance or in a set of regulations, or in a combination of the two, they will be ineffective without an adequate force of trained inspectors and an orderly system of administrative enforcement. It is most desirable that both the inspection service and the legal procedures for abatement should be coördinated in a given area.

Value of Coördinated and Systematic Inspection—The examination of plans for new construction and the inspection of actual work performed on new buildings may well be carried out—as at present—by building departments and fire departments. So far as inspection of occupied dwellings is concerned, we have in many cities at least three different groups of inspectors—those of the health, fire, and building departments—operating in the field. It would seem wise to consider the feasibility of co-ordinating such field inspection services. Instead of sending an electrical inspector one week, a fireman the next week, then a plumbing inspector, and finally a sanitary inspector to the same house, it might be possible to correlate the work of these inspecting staffs so as to promote efficiency and economy. In small communities it may often be impossible to have more than one inspector reasonably qualified to deal with the various fields involved. Such an inspector might most logically be attached to the local health department, but in one city the building department makes all such inspections in residences except for fire hazards and this plan works satisfac-

torily. In cities where three groups of inspectors are working it should be feasible to provide for some coördination of effort without impairing the legal powers of any department concerned.

One of the major advantages of a combined or coördinated inspection service would be the unification of records, so that copies of all information relative to a given piece of property could be made available in one place to all groups concerned with housing (including relief and welfare agencies, whose interest in, and possible contribution to, improved housing regulation is perhaps too little recognized).

It is obviously essential that the inspection staff should be adequate in number, capacity, and experience. Elimination of overlapping inspection responsibilities should increase the effectiveness of available personnel. At least one recent study of inspection practice suggests that little or no more man power would be required for thorough and systematic inspection in problem areas than is now used for sporadic inspection in response to nuisance complaints.

The common practice of inspection only on complaint is completely ineffective. Inspection procedures should be designed not only to secure corrections in individual premises but also to give an over-all measurement of housing defects and needs throughout the problem areas of a community, as a guide to appropriate long-term programs of enforcement or reconstruction. The importance of systematic inspection in developing effective housing regulation can hardly be overstressed. Inspection of this type, together with enforcement graded according to the quality of housing areas, is the distinguishing feature of the notable recent work in housing inspection by the Memphis Health Department.¹⁰ The Committee on the Hygiene of Housing has developed and tested an appraisal technic to serve the same purpose, applicable in any city

and suitable for execution by the health department or a coöperating group of city agencies.¹¹

Systematic inspection is practised in Cincinnati under a modernized building code with comprehensive housing regulations for both new and existing dwellings. For at least ten years substantially all residential inspections, except those for fire hazards by the fire department, have been done by the building department. This department has a special force of housing inspectors which under a special supervisor inspects annually every dwelling in the major substandard housing areas, issues orders, and makes follow-up inspections to see that the orders are complied with. For several years every building in these areas has been graded each year as to condition and occupancy, as has each census tract in the area. Vacation of unfit buildings and of those containing serious violations of the law is routine, as is condemnation of unsafe structures. For a period of ten years an average of from two hundred to four hundred dwelling units in unfit buildings have been demolished annually under orders of the department.

Proposals now under consideration in the City of Hartford, Conn., suggest a possible realistic method of coördinating not only inspection methods but the underlying regulations of various departments. In 1939 an act was passed by the state legislature providing that

"... the Court of Common Council of the City of Hartford, in addition to the powers vested in it by law, shall have power . . . to make, alter and repeal ordinances for the following purpose: to establish a coördinating authority for the enforcement of police powers relative to the repair, vacation and demolition of buildings and dwellings, which coördinating authority shall include the Chief of the Fire Department, the Health Officer and the Building Supervisor."

* The joint committee established under this act has outlined its functions as follows:

1. To assign, through proper legislation or administrative changes, definite and appropriate inspection responsibilities of each inspectional agency.
2. To formulate procedure, reporting and recording forms designed to get maximum coverage and minimum duplication in each inspectional field.
3. To establish policies and plans for systematic inspection of all substandard buildings and dwellings in the city.
4. To provide for centralized maintenance of all inspection records and reports of each building in the city.
5. To establish in the committee office a definite procedure for:
 - a. Reinspection or "follow-up" inspection by special inspectors; and
 - b. The handling of complaints in the several fields of inspection.
6. To serve as a central clearing house for information on the conditions of buildings needed by citizens, other governmental agencies and local organizations.
7. To formulate, as needed, recommendations to the Court of Common Council and the State Assembly relative to desired additions or modifications in building and dwelling maintenance standards.

Analysis of the Hartford ordinances prior to the proposed coördination showed that 19 different items of inspection were specifically recognized, 4 being assigned to the health department alone, 3 to the building department alone, 1 to the fire department alone, 5 to both the health and building departments, 2 to both the health and fire departments and 4 to both the building and fire departments! Under a new plan proposed by the joint committee, 9 of these problems would be assigned to a combined inspectorate of the building and fire departments, and 8 to the health department, leaving 2 (ventilation and heating) to be jointly handled. Both the inspection staffs would operate under the direction of a group representing all three departments.

The Place of Joint Enforcement Procedure—The experience of other cities seems to support the view that joint departmental action, even when informal, may be much more effective than

the customary programs of separate enforcement. The recent cases of two small Eastern cities are enlightening. In one community the health department, about two years ago, employed a sanitary engineer to initiate a systematic program of housing inspection. The department has been working closely with the local housing authority on the program of equivalent elimination embodied in the agreement between the city and the housing authority under the U. S. Housing Act. Some two hundred dwelling units were selected—as a result of the health department's inspection program—as being substandard to a degree requiring immediate action. The owners of one hundred of these properties have thus far been given orders to appear before a committee made up of representatives of the health department, the building inspector, the fire chief, and the housing authority. The owners have been given a chance to be heard after the specific requirements necessary to bring each building up to standard were outlined. They have been offered the choice between rehabilitation or demolition, and not one of these owners has legally contested the action of the committee.

The other city has a part-time health officer, a part-time sanitary inspector, and no housing authority. The sanitary inspector, along with the building and plumbing inspectors, was recently sent out to cover a group of dwellings which had been the subject of frequent complaints. The owners were summoned before a committee consisting of the health officer and the three inspectors concerned, and were given notice as to the varying periods of time in which specific gross violations must be corrected. Here too compliance has generally been obtained to the extent that the current shortage of building materials would permit.

It seems clear that much can be accomplished without waiting for the de-

velopment of fully coördinated legal instruments, by the simple expedient of pooling the technical knowledge and prestige of health, building, and fire departments¹² for enforcement purposes in the worst slum areas. The alert chief executive can bring about such joint effort by administrative action wholly within his present powers.

In all such programs, the authorities concerned must have the backing of informed and sympathetic public opinion, if substantial results are to be attained. Such support depends on organized campaigns of education and a basis of public confidence in the officials concerned. The support of the press is vital, and concerted action on the part of organized labor, citizens' housing councils, and other nonofficial bodies is of the greatest value.¹³

TOWARD A SYNTHESIS OF REGULATORY AND CONSTRUCTIVE PROGRAMS

Thus far we have been concerned only with the adequacy of regulations for their specific task of controlling the physical conditions of housing. But it should be recognized also that police power regulation can be made a powerful instrument in shaping long-range housing policy, and particularly in aiding the creative work of housing authorities and planning bodies. Here the task is obviously not that of the enforcement agencies alone, but of the entire municipal administration.

A general limitation of our present housing regulations is their usual failure to provide for enforcement other than by mandatory abatement, demolition, closure, or token fines. Housing consciousness, on the part of both the general public and the courts, has reached a new high level and it is reasonable to suppose that considerable support would be given to measures calling for a policy of economic discrimination against unfit dwellings; stipulating, for example, that

in premises where substandardness is established by objective appraisal, rents may not be increased¹⁴ or possibly even that they may not be maintained above a level set to penalize substandardness.

A second and even more striking weakness of restrictive housing laws is their general lack of any intent to employ the sanctions of police power in support of creative programs such as those of municipal housing authorities and planning commissions. Our pattern of housing regulation has been largely handed down from a time when there was no background of positive public policy for housing and city planning. Increased governmental aid on the constructive side, represented in the past few years by the public housing program and by federal aid to planning bodies, has brought strong potential forces into play for community rebuilding and for the strengthening of police power controls. If fully recognized and exploited, these forces may revolutionize our attitude toward law enforcement and the instruments under which it is carried out.

The development of official local housing standards coupled with sound inspection and appraisal technics should warrant the drafting and testing in court of more effective regulations to deal with buildings and areas below a certain standard. For example, the courts might now sustain a law which would provide that seriously substandard dwellings shall be taken out of use after a limited period allowed for amortization of any remaining economic value of the structures. Local authorities might be authorized within certain limits to forbid rent collection after an appropriate deadline.¹⁵

Not only should such laws, if sustained, help in deflating speculative property values which have blocked the replanning of slum areas, but they would serve notice on communities as to the number of dwellings to be replaced

by a given date. Local housing and planning bodies would thus be stimulated to more vigorous programming and search for funds. Furthermore, since the economic value of the worst houses would presumably have been liquidated during the period of grace, it should be possible within a reasonable time to clear slums without payment for such buildings. This is accepted practice in British slum clearance, and the lack of similar powers in America is estimated to have cost our public housing program, in a typical year, nearly \$500 per new dwelling unit built.¹⁶

We must begin to think of comprehensive housing programs in which systematic inspection and official designation of substandardness by areas will serve as beacons to guide the agencies of reconstruction into slum areas where improvement under the police power is hopeless, but which may offer prime opportunity for governmental or private rehousing or other rehabilitation projects. In other words, the vigorous and imaginative exercise of regulative powers may supply for the first time a method of earmarking whole districts, helping to indicate both the relative urgency and the types of constructive programs needed for improvement or rebuilding.

Several types of post-war reconstruction schemes now being officially considered are chiefly based on large-scale slum clearance and housing construction, both as a primary aim of a democratic peace and as a basic type of public works to cushion the post-war economic readjustment. Such programs may be expected to put a premium on effective housing regulation under the police power. Large-scale reconstruction will require closer definition and measurement of substandard housing areas than we now possess, both to delimit sharply the areas needing rehabilitation and to indicate the nature of the remedies required. In the interest of sound public

policy, such reconstruction programs should be able to operate with reference to legal standards which carry effective economic sanctions, so as to obviate the payment of public works funds for the purchase of dwellings maintained in gross violation of the law.

The prospect of these post-war programs should be used as leverage to bring about a strengthening of housing regulation hitherto impossible. In recent years over thirty states have passed a progressive and wholly new type of local housing authority legislation, in direct response to the benefits offered by the public housing program. Similar results should be made to grow out of the post-war redevelopment schemes, by making participation in their benefits conditional upon the development of adequate local housing standards, systematic appraisal and enforcement in substandard areas, and effective means for bringing down the purchase price of substandard houses in clearance areas.

NOTES

1. These contacts were made by the former Subcommittee on Housing Codes, under the chairmanship of the late Morton G. Lloyd of the National Bureau of Standards.

2. The exact form of the requirements must of course vary with height of buildings, class of construction, and type of use, but the degree of protection secured should be essentially the same.

3. *Ordinance No. 384*, approved March 6, 1941. A similar ordinance with respect to rooming houses (No. 507) was approved June 28, 1941.

4. It has not been possible here to deal with certain questions which in effect relate to the legal bases of housing regulation—such as the limits within which the courts will support retroactive standards for the improvement of existing buildings, and the theoretical and practical differences between enforcement at the level of mandatory repair or closure on the one hand, and demolition of substandard structures on the other. These questions and their meaning for the drafting and enforcement of housing regulations will be explored in future studies of the committee.

5. See *Preparation and Revision of Building Codes*, National Bureau of Standards, *Report BMS 19* (May, 1939); and *Building Code Arrangement*, Building Code Correlating Committee of the American Standards Association (Mar. 5, 1937).

6. *Recommended Building Code Requirements for New Dwelling Construction; with Special Reference to War Housing*, prepared by Subcommittee on Building Codes, Central Housing Committee on Research, Design, and Construction (April, 1942, preliminary issue; printed edition to be published by National Bureau of Standards).

7. Important administrative questions arise in this connection. The usual type of occupancy regulation

in terms of cubic feet per person tends to be meaningless except for enforcement in extreme cases, since usually no agency is made responsible for designating the legal capacities of dwelling units and for checking the observance of these capacities. Occupancy licenses would make it possible to designate and post the maximum number of persons permitted to occupy each dwelling in a licensed tenement or other structure, and should help materially in establishing legal responsibility for wilful violation by either tenant or landlord.

8. Provisions under this heading will tend to overlap with zoning regulations, against which they should be checked in any particular locality.

9. Similar statements of purpose apply, of course, to the remainder of these topics.

10. See Enforcement and Subsidy in the Control of Slums, L. M. Graves and Alfred H. Fletcher, in *Housing for Health*, Committee on the Hygiene of Housing (1941), pp. 18-36.

11. This technic and its application to local housing policy are described in the recent report of the Subcommittee on Appraisal of Residential Areas, An Appraisal Technique for Urban Problem Areas as a Basis for Housing Policy of Local Governments, *Pub. Health Rep.*, 57, 9 and 14 (Feb. 27 and Apr. 3, 1942); available as *Pub. Health Rep. Reprint No. 2359*, free from the Committee on the Hygiene of Housing, 310 Cedar Street, New Haven, Conn., or at 10 cents per copy from the Superintendent of Documents, Washington, D. C.

12. While these three are usually the agencies most directly concerned with housing enforcement, it should not be forgotten that numerous other official and unofficial groups are concerned with the effectiveness of housing regulation and may be in a position to give such regulation effective support. For example, in one city studied by the committee the health department reports that it coordinates its housing inspection with the work of—or makes known its findings to—the following agencies: Official—Building Department, Fire Department, Police Department, Welfare Department, City Plan Commission, City Comptroller, Zoning Board, Police Magistrates, City Housing Authority, City Law Department, Federal Rent Administrator; Non-official—Press, Housing Council, Real Estate Board, Women's Civic League.

13. For an example of the rôle which can be played by a favorable press, see Housing as a Health Officer's Opportunity, *A.J.P.H.*, 32, 9:1001-1004 (Sept.), 1942.

In Cincinnati the Better Housing League, a citizens' housing agency, cooperates closely with the housing bureau of the building department. As buildings are ordered vacated or condemned, the bureau routinely notifies the League, whose visiting housekeepers then set about to find homes for the tenants so that delay in following through on vacation procedures is avoided and the bureau chief freed from the handicap of concern about getting tenants out.

14. An act embodying substantially this principle, the so-called Minkoff Law, is in force in New York State: Laws of New York, 1938, ch. 675.

15. There is an interesting ancient precedent for this particular type of action. In the reign of Queen Elizabeth two landlords who had bought and subdivided a tenement in Hog Lane were fined and committed to the Fleet Prison; and it was specifically provided that the indigent tenants should remain in their quarters without payment of rent—the buildings to be torn down on their departure.

16. "Because of the failure of municipalities to exercise the power of clearing slums during the last one hundred years they are now paying dearly to purchase them. The present United States Housing program proceeds on the announced theory that slums will be removed by contracting with the cities to exercise their police power. Realistically, however, it seems that the greater portion of the immediate slum demolition is going to be incident to the purchase of land sites in slum districts. This will be counted as 'equivalent elimination' under the Housing Act, but it is not accomplished through use of the police power but rather by compensation being paid. The cost of acquiring slum buildings—not land—under the contracts for 1939 was placed at \$23,871,431. At the same time some 49,449 dwellings were to be erected on slum or partial slum sites where these buildings were purchased. This means that for every new dwelling unit erected in a slum or blighted area approximately \$480 is to be paid for slum improvements standing upon the property.

"In some cities this cost of demolition runs to sizable figures: in New York and Boston the total exceeds two and a half million dollars; in New Orleans, Baltimore and Pittsburgh it approximates one and a half million dollars, and there are a number of other cities where it approaches that figure. Thus for every new dwelling unit built in a slum area in which it has been necessary to buy substandard improvements, the community is charged nearly \$500."—William J. Barron, *Low Cost Housing and Slum Clearance*, unpublished doctoral dissertation, Yale School of Law (1941).

FUEL RATIONING

DURING the first chilly fall days there was released by the Fuel Rationing Division, OPA, a report bearing upon the Medical and Public Health Aspects of Heating Oil Rationing. This is a valuable document and, to say the least, is seasonal. It very sensibly reviews, in so far as scientific knowledge permits, the relationship between heating, ventilation, comfort and health; and one senses an intimation that, while heretofore our tendency has been to explore just how comfortably warm one might be without injury to health and efficiency, the present situation demands that we learn now just how uncomfortably cool one might be and still remain alert, precise, and well.

A temperature of sixty-five degrees Fahrenheit is to be provided for oil-heated dwellings and apartment houses, with higher ranges in special circumstances: where there are young children, the aged, the sick. Advice is given as to the desirability of wearing more clothes, and there is a delicate and restrained reference to "an extra undergarment." Adjustment to these somewhat chilly living and working conditions is going to be difficult for the citizenry of the United States. Doubtless there will be many landlords who will, in the name of patriotism, hew to the freezing line; and many tenants will attempt to settle old scores by reporting guilty and unguilty owners alike. Possibly, where sanitary or other codes require a certain heat performance on the part of building operators, the local health departments concerned may receive so many complaints they will wish that the subject of heat rationing had never been mentioned.

Unfortunately there is a paucity of scientific knowledge as to the best optimum indoor heat for homes and working places during winter, and, strictly speaking, there is no such thing as an optimum temperature, applicable in all circumstances, as humidity, air movement, activity of those exposed, and how warmly they are garbed, enter definitely into the situation. Our previous standards, therefore, have rested upon assumption rather than upon accurate information, and fuel oil rationing on a national scale may permit the accumulation of worth while data on this important subject. But even in the absence of such information, it seems likely that fuel rationing and its consequent lowered indoor temperatures will do

good rather than harm. The temperature at which offices and living rooms have been kept since the general adoption of central heating has been a part of soft living, perhaps an index of a national softening. No other nation in the world has so pampered itself in this direction as has the United States of America; and visitors from other countries, inured to inside temperatures from sixty to sixty-five degrees Fahrenheit, find it hard to tolerate the headiness produced by the hot, dry, stagnant air in our homes and public buildings.

Be all this as it may, those responsible for the public health would do well to inform themselves thoroughly as to conditions required or permitted under the fuel rationing rules. Further, it would seem wise for them to explore and study local problems and potential problems so that, in so far as is practicable, they may be in position to prevent hardships, critical situations, and violations. However, in spite of such foresight, complaints will inevitably arise and many local health officers will be called upon to investigate and to serve somewhat as arbiters. In the circumstances, it might be well for health departments to institute a simple procedure for handling such complaints as expeditiously and as unharassedly as possible.

Sixty-five degrees Fahrenheit would be as a roaring furnace compared to what the troops undergo in Alaska and Iceland.

WHAT AND WHO IS AN EPIDEMIOLOGIST: CURTAIN

AS forecast in the editorial section of the September *Journal*, with this issue the discussion *What and Who Is an Epidemiologist?* is brought to a close. The discussion has been interesting and to some extent productive, though we are inclined to doubt that it has changed many opinions. Some will continue to insist that an epidemiologist is never to be found indoors but only in the byways and hedges, tramping around on the uppers of his shoes, having worn away the soles in a detective-like search for the common source of a local outbreak. Others, who have thought of the epidemiologist as being primarily concerned with the laboratory life of causative organisms, will persist in garbing him in a white coat; and many will remain steadfast in refusing to believe that an epidemiologist is nearby unless they hear, and hear distinctly, the click and hum of his calculating machine.

We are not sufficiently omniscient to settle the matter, and like Frank Stockton, with *The Lady or the Tiger*, must leave *Journal* readers to their own solution of the mystery *What and Who Is an Epidemiologist*.

The two last received letters on the subject are presented below:

Harold F. Gray, Sanitary Engineer, of Berkeley, Calif., writes as follows:

After having spent thirty-five years in, and around the fringes of, public health work, some of the replies to your editorial on "What and Who Is an Epidemiologist?" (*A.J.P.H.*, 32:414 (Apr.), 1942) are either amusing or distressing.

Offhand, and without thinking, I can

answer the question promptly by giving the names of a few men: L. L. Lumsden, W. T. Sedgwick, W. A. Sawyer, H. R. Carter, K. F. Meyer, W. H. Frost, A. W. Freeman, L. W. Hackett, William Budd, John Snow, and P. L. Panum; and there are many others.

There can be several kinds of epi-

demiologists, of which the best and most useful is the "shoe leather" man, who works all day and part of the night getting the facts down on cards, and spends the rest of the night down on his knees on the floor of his hotel room, endlessly shuffling these cards into piles until, he hopes, a significant grouping turns up.

How does one get to be an epidemiologist? No one can tell in advance. A well rounded public health training helps, but our greatest epidemiologists had merely the usual medical training of their time. Chance, the direct contact with epidemics, gives the man who is intrinsically an epidemiologist the opportunity to show forth his talents. But the inquiring mind, the desperate necessity of arriving at the truth without blinking at inconvenient facts, the determination to get all the facts, plus a certain facility (perhaps inspiration) in asking the significant questions, must be born into

a man, if he is to be an epidemiologist.

Of the answers so far published, those of Allan W. Freeman and C.-E. A. Winslow are the best, probably because they have been matured out of rather long experience, but J. E. Perkins's letter has its points, and shows that he has worn out his share of shoe leather. But I cannot agree with Dr. Perkins that epidemiology is a science. It is an art, employing skillfully many sciences in its practice.

The definition given by Dr. Adams, limiting the epidemiologist to "a physician (M.D.) who investigates," or "a medical inspector," is far too narrow. Louis Pasteur was not a physician, but he was an epidemiologist at heart. Nurses, bacteriologists, veterinarians, engineers, entomologists have upon occasion and opportunity done excellent epidemiological work.

The practical definition of an epidemiologist is Biblical (Matthew, 7, 16) "By their fruits ye shall know them."

Charles F. Bolduan, M.D., Director of the Bureau of Health Education, New York, N. Y., as a comment on the subject under discussion, quotes this from the third edition of his book, *Public Health and Hygiene*:

The epidemiologist should, of course, by a physician and have had training in laboratory work and in statistical methods. It is highly desirable that he maintain a hospital connection in order to keep himself constantly abreast of clinical medicine. Knowledge of a foreign language is an asset. To be successful the epidemiologist must have imagination and a strong leaning to curiosity. He will constantly be asking himself, Why? Why do epidemics of poliomyelitis come in summer? Why has scarlet fever mortality declined so markedly? Why does leprosy spread in certain parts of the world and not in others? Why is diabetes so much more prevalent among Jews? Why is diabetes mortality among married and

widowed women over forty-five years nearly three times higher than it is among unmarried women of the same age? Why the higher incidence of peptic ulcer among males? The greater prevalence of gall-bladder disease among females? The cyclic recurrence of measles, meningococcus meningitis and some other infectious diseases?

It is the constant search for answers to such questions that results in medical progress and in the more effective control of disease.

At the present time epidemiologists having all the qualifications described above are not numerous. In most health departments the epidemiologist confines his attention to the communicable diseases.

LETTER TO THE EDITOR

TO THE EDITOR:

Enemy action and the greatly increased burden of the war effort have so seriously curtailed the transportation of petroleum products that households this winter can be heated only by limited supplies of fuel oil; consequently, the problem of maintaining health in temperatures lower than usual is not only difficult, but *must* be solved to prevent illness. Before the war, the East Coast received about 95 per cent of its oil by means of tankers. So many of these tankers have gone down that an extremely serious dislocation in our petroleum distribution system has come about. In view of the resultant urgent necessity to share limited supplies fairly, the Fuel Rationing Division of the Office of Price Administration has drawn up a plan for the rationing of fuel oil in thirty states designated by the War Production Board. The fullest patriotic coöperation of your profession will be necessary, and without doubt will be given.

Basic rations for fuel oil will be allotted householders by the Office of Price Administration through its rationing boards. This ration will be based upon past consumption (adjusted for normal weather) and upon the thermal efficiency of the house as indicated by a heat loss floor area formula developed and tested by top flight heating engineers. Provision will also be made for auxiliary rations to households in which illness or the infirmities of old age make necessary temperatures higher than that afforded by the basic ration.

Application for such auxiliary ration will be made to the local rationing board by the consumer. His application will

have to be supported by certification by a licensed physician. In certifying, the physician should give the date, the name and address of the householder, and should certify to the Office of Price Administration: (1) whether the illness is of an acute or chronic nature; (2) whether it is the kind which requires higher indoor temperatures, (3) the approximate temperatures required, (4) the approximate period for which this supplemental base heat is needed. The physician may at his discretion state the nature of the illness and give any additional information which will guide the board. This certificate should be given to the applicant, who will file it with the local rationing board.

The success of the rationing plan in meeting the fuel oil emergency equitably and effectively will depend in large part upon the kind of patriotism and conscientious coöperation that the medical profession has always given in times of emergency.

It is planned that Advisory Committees of three members, comprised of two licensed physicians and the County or Local Health Officer will be set up by the County or Local Medical Association upon request of the local rationing board. These Advisory Committees will function by reviewing the cases of the certificates questioned by the local rationing board when the board wishes more detailed information and professional opinion. I am sure that the medical and public health professions will coöperate actively in setting up and operating this important auxiliary advisory body.

FILM NOTES

The ogre of budgetary limitations always rears its ugly head when health educators lay their plans for motion pictures. Films are expensive to produce and yet health agencies have succeeded in making commendable pictures on budgets that would look like small change to the professional Hollywood producer. Non-commercial health films, of course, are not expected to be the equal in certain respects of pictures made for theatrical use. Still the ambitious health educator has long cast an envious eye toward Hollywood—wishing that he might duplicate to some extent at least the film capital's excellent settings, photography, casting, and other facilities necessary to the production of an expertly finished picture. The health educator is realistic enough to know that such resources are not apt to be within his reach. But the hope has persisted that perhaps the professional producers themselves would take specific cognizance of health as a film subject. At last, as a war activity, this has happened—the lead having been taken by such well known companies as Universal Pictures, Walt Disney Productions, and Metro-Goldwyn-Mayer.

"Keeping Fit" is the title of Universal's contribution to health education. This film is one reel in length and is scheduled for release the latter part of October. Preview audiences have re-

ceived this picture enthusiastically. It is produced with the usual Hollywood finesse, with the advice and coöperation, we understand, of official federal agencies, and succeeds in blending entertainment and health instruction in a skillful manner. The importance of personal hygiene in relation to national strength is convincingly demonstrated in this picture, due emphasis being given to nutrition, sleep, relaxation, exercise, and proper medical care. These elements have been woven into a story that moves at a brisk tempo, thanks to a well written scenario and a cast of capable actors, including some of Hollywood's stellar performers. Watch for this picture at your local theater and exploit it in health department publicity releases. It is an effort that deserves the support of all health agencies.

Walt Disney Productions will offer two subjects of public health import. One is entitled "Defense Against Invasion," which is designed "to spread the gospel of immunization among Americans." Disney, with his usual flair for simplifying technical subject matter, depicts the battle that takes place in the body between invading organisms and the "corpuscle soldiers." The physiological reactions involved in the process of immunization are illustrated so clearly that this film has been hailed as "an ideal teaching medium for young children." The second Disney production is called "Food Will Win the War." Through pictorial statistics, America's tremendous food resources are shown, and the importance

Please address samples of printed matter, comments, or other editorial contributions to the editors at One Madison Avenue, New York, N. Y.

of food to a world at war and in the reconstructed world to come is convincingly set forth.

Another addition to the series of health films will come from Metro-Goldwyn-Mayer which will issue a picture entitled "The Magic Alphabet." This will tell the story of the vitamins.

Along with these professionally made productions, it is a pleasure to include a reference to a film made by the National Tuberculosis Association. "Middletown Goes to War" is its title, and we doubt that Hollywood could have done a better job if forced to produce this film within the limitations of the N.T.A.'s resources. The picture deals with a timely theme—the awakening of a community to the urgent health problems created by an influx of defense workers. The situations pictured are typical of those that communities throughout the land have faced since American industry geared itself to war production. As the story unfolds, one witnesses a clear-cut demonstration of the democratic way of life and this aspect of the film impresses the onlooker as much as does the picture's central theme—health protection for all. Knowingly or unknowingly, the producers have turned out a film that is a good implement of health education and at the same time a morale-builder in that it pictures the kind of community life, the kind of people, the kind of institutions, and the kind of principles that we are fighting to preserve. A competent cast—which, incidentally, reveals Dr. H. E. Kleinschmidt as an actor of no mean ability—enhances the film's general excellence.

To obtain "Middletown Goes To War," consult your state or local tuberculosis association or write to the National Tuberculosis Association, 1790 Broadway, New York, N. Y. The film is suitable for showing to many groups including health councils, industrial groups, schools, and theater audiences.

NOTES ON HEALTH PUBLICATIONS

Our bulging file of annual reports for the year 1941 continues to be swelled by additions, even at this late date. Among the late arrivals, two noteworthy reports deserve mention here.

From the Davidson County Department of Health, Nashville, Tenn., comes a fact-filled and nicely written summary of that agency's activities during 1941. This annual statement is considerably condensed in comparison with the department's previous reports. Yet it gives the reader a good all-round account of the work, policies, and organization of this resourceful health unit. Illustrations depicting certain phases of the department's clinical and field work are liberally sprinkled throughout the text and enhance the report's general effectiveness. Through the years steady gains in health conservation have been achieved by this department, but only a modest reference is made in the foreword of the report to the Health Conservation Contest awards which the department has received consistently since 1935. We congratulate Dr. John J. Lentz, the department's director, and his staff upon a record that many health agencies might well envy.

The 1940-1941 annual report of the Department of Health of Peoria, Ill., is a well balanced statement of 50-odd pages of compact information presented in a thoughtful and orderly fashion. It should give the people of Peoria an opportunity to ascertain in a clear-cut way just what their health department is doing. A notable record of health advances is reported in this summary. For instance, there were no deaths from diphtheria during the 2 year period covered by the report. As to cases of this disease, there were none in 1940 and only 2 in 1941. Dr. Sumner M. Miller, the Commissioner of Health, and his coworkers have every reason to feel proud of the report and the progress

reflected therein. As to make-up, the report is attractively printed and illustrated. The title is also good—"The Health of One Hundred Thousand People." (Incidentally, why can't all annual reports be given titles? An arresting title will entice many readers who would not be attracted by a document merely labeled—Annual Report.)

The 1942 edition of *Accident Facts*, published by the National Safety Council, 20 North Wacker Drive, Chicago, Ill., is a unique compendium of information for all who are interested in any phase of the accident prevention program, either from an administrative or educational angle. The data in the current edition with reference to occupational accidents and hazards will be of great value to an increasing number of state health departments as their work in the field of industrial health, in coöperation with the U. S. Public Health Service, is expanded. Furthermore, at least a few state and local health departments have recently shown a marked increase in interest in home, school, and farm safety. In this connection it should be stated that from the educational angle, the health department has experience and technics that should prove of outstanding value in controlling home accidents. The booklet of course contains a wealth of information regarding traffic accidents and other phases of the accident problem. A helpful index, pictorial charts, and a mine of statistical information make this a publication well worth the cost—20 cents to 50 cents per copy, depending upon the quantity ordered.

"Facts That Tuberculosis Patients Should Know" is the title of an excellent guide prepared and distributed by the Bronx Tuberculosis and Health Committee, 226 East Fordham Road, Bronx, N. Y. The text of the publication is presented in question-and-answer

style. The questions were selected from inquiries actually made by patients and the range of the queries covers the whole field of tuberculosis. The authors have been particularly successful in supplying clear, sound, and informative answers. This is an exceedingly practical publication, easily read, and so organized that the reader can readily turn to the questions in which he is interested. The committee responsible for this publication has made a valuable contribution to popular literature on tuberculosis.

A timely addition to the series of booklets issued by the Life Conservation Service of the John Hancock Mutual Life Insurance Company is entitled "Headache—A Signal." The text was written by Dr. W. W. Bauer whose health essays are noted for their naturalness of expression. This author has a knack for clothing his thoughts in good, everyday folk words—the words that people use when they get together to "talk things over." He has used this style to good advantage in the John Hancock booklet which gives all the facts about "what makes the head ache." The cover, illustrations, and typography of this booklet are likewise noteworthy and in keeping with the John Hancock standard. Copies of "Headache—A Signal" are available without cost from the company's offices in Boston, Mass.

A report of the New York State Trichinosis Commission has been published under the title "The Meat You Eat." This is a thoroughgoing analysis of the trichinosis problem and would serve as a valuable reference source for workers interested in this health hazard. Unlike the usual dry legislative document, this report is interestingly written and illustrated with splendid photographs, several charts, and a cartoon of "the little pig that went to market so that people could go to the hospital with

trichinosis." An appendix to the volume includes copies of various legislative acts and regulations imposed in New York for the control of "tricky trichinosis." Information concerning this report may be had by addressing the New York State Trichinosis Commission, 94 Broadway, Newburgh, N. Y.

A new monthly publication has been launched by the Department of Public Health of Flint, Mich. Its title is "Information Pleases"—a title, by the way, that is intriguing and that has a certain quality which the advertising gentry call "pull." The circulation of this publication will be limited to a selective list of one thousand, including doctors, dentists, school officials, social agencies, libraries, and parent-teacher associations. The editorial policy of the publication will be that of interpreting the health department's program rather than reporting news items. The first issue devotes its space to brief summaries of the work of certain divisions of the department and carries a "feature article" on the training and examination of food handlers. We like "Information Pleases" and believe that its monthly appearance will be welcomed by those fortunate enough to receive it.

STILL MORE ABOUT POSTERS

Perhaps readers of this section feel that we have "harped" on the subject of posters almost too much. We beg your indulgence, then, as we turn once more to this topic. Since posters are playing such a vast part in the current propaganda campaign of this and other nations, it is perhaps worth while, even at the risk of becoming repetitious, to keep health educators informed of the latest trends regarding this medium which Dr. George Gallup, head of the American Institute of Public Opinion, has recently called "the most effective and dependable means for

communicating with the masses of the population."

Two important concepts concerning the use of posters were set forth a short time ago by the Graphics Division of the Office of War Information. The director of that agency maintains that posters achieve maximum usefulness when used as a *part* of a campaign in which radio, public speeches, publications, and the like are also brought into play. In other words, posters *alone* should not be depended upon to "put over" an idea. Unless integrated with other media for reaching the public, posters are apt to fail to fulfil their mission. Moreover, posters should be keyed only to urgent, pressing needs of the moment. If a dozen different posters are issued on a dozen different subjects and all of them displayed simultaneously, the public becomes over-dosed and punch-drunk because all the admonitions and instructions cannot possibly be followed. Consequently, under such conditions, posters work at cross purposes and the public does not take them seriously.

Regarding the actual work of preparing a poster, here are a few suggestions which come from *Art News*, an authoritative publication on all types of illustrative material:

First, determine in a general way the type of design and lettering. Certain ideas can best be presented by pictorial illustrations, while others need a powerful word message. In no design can these two elements be given equal importance and be seen to advantage. Decide which type is the one for your purpose. Then subordinate one of the elements, else a continuous battle will take place for attention. Usually it is better to subordinate the word message, although some lettering is used in practically all posters. Feature only *one* big message—more than that divides attention.

Unification in poster design may also

be achieved through the color scheme. A great number of colors may give a poster brilliancy and life, but when the design is displayed in company with others, it will blend into the general effect and its value will be lost in the shuffle. If the design is to stand out, it must be dominantly of one color.

Repetition of a thought, a phrase, a slogan, an appeal in posters is desirable. Repetition in the case of posters may be likened to seeing people . . . the more often we see them the better we know them.

All posters should be planned for mass appeal without distinction as to class, income group, occupation, political party, or other grouping. Posters reach all the people in exactly the same way in cities and towns throughout the nation—people see posters in passing. They therefore require a maximum of simplicity in design so that the message to be conveyed registers quickly and in such a way that it becomes firmly fixed in people's minds.

All these suggestions are pertinent to the health poster and to a certain extent a series of nine industrial health posters recently issued by the U. S. Public Health Service fulfil these desirable specifications. This set of posters features everyday precautions that keep workers "on the job"—good food, exercise, cleanliness, rest, medical and dental care. While they are distinguished by colorful design and by commendably terse health messages, one cannot help but entertain some reservations as to the artist's conception of the worker. It strikes us that there is perhaps too much unpleasant exaggeration in the artist's interpretation. Unable to decide whether or not these posters would have general appeal, comments were solicited from several sources. Here are the criticisms received:

"These posters have their virtues as well as certain glaring faults. They do catch the

eye—but I see them as funny pictures. The health messages would have escaped me entirely had I not studied each poster."

"These posters are certainly a marked and revolutionary departure from the usual type of poster issued by government agencies. At first glance, I liked them. On closer examination, I seriously questioned their value as a medium for health instruction."

"They are amusing—but will the worker get the proper inspiration from them?"

"I like the technic and the bright colors. I think, however, that the conception of the worker is unflattering."

"These posters are corking—they are unusual and will appeal to the men behind the machines."

Incidentally, one poster in this series has been widely publicized in the press. Perhaps you have seen a copy of it in newspapers. It shows a dentist whose left hand bears six fingers. Whether or not this extra digit was included intentionally, we do not know. But at least this additional finger has served the purpose of garnering publicity.

If interested in securing these posters on industrial hygiene, write to the Superintendent of Documents, Washington, D. C. They are priced at 30 cents per set, with a 25 per cent discount on orders of 100 or more sets.

EDUCATING HEALTH EDUCATORS

An innovation in practical training for health educators is announced by the Bureau of Health Education of the American Medical Association. Upon authorization of the association's Board of Trustees, the bureau and related departments will accept from time to time two graduate students, or two undergraduate students recommended from established educational institutions, for the purpose of observing the methods and technics employed in the association's extensive health program. No tuition fees will be charged, although accepted students will be expected to defray their own expenses, including transportation for short field trips in the Chicago area. It is recommended that students can spend their time to

best advantage if attendance is planned between December 1 and May 1, when the association's activities are in full swing.

The program will afford students the opportunity of observing actual work performed by the principal departments of the American Medical Association engaged in health education. Following an orientation course surveying the entire organization of the association, intensive work will be undertaken in the following bureaus:

1. The Bureau of Health Education—Students will be given instruction in office organization, the development of source and information files, the compilation of bibliographies, the formation of plans for cooperating with medical societies, methods of handling correspondence with special reference to letters from lay inquirers seeking health information, and the preparation of pamphlets including problems of lay-out, illustrating, and printing. In this bureau, students will also have an opportunity to participate in the development of radio dramatizations and the preparation of talks and speeches for lay groups.

2. The Bureau of Exhibit—This bureau will demonstrate various types of exhibits and students will be asked to outline steps in the development of a suitable exhibit for a specified type of audience. The motion picture and the slide will also be considered.

3. The Bureau of Press Relations—In this bureau, students will observe how technical papers are translated into terms understandable to newspaper readers and how distribution is effected through newspaper press associations, the radio, and other media of public information.

4. The Bureau of Investigation—This bureau will offer students an opportunity to observe how nostrums, quackery, and pseudo medicine are combated in cooperation with federal agencies, better business bureaus, and other groups. The effects of new federal legislation on foods, drugs, appliances, and advertising will be studied.

The Editorial Department of *Hygeia* will demonstrate the selection and preparation of manuscripts and related problems.

This comprehensive program will afford excellent opportunities for students

to gain first-hand information on practically every subject related to health education. Inquiries concerning the program should be addressed to Dr. W. W. Bauer, Director, Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago, Ill.

AN EDITORIALETTE:

"CONCERNING ACCELERATED PROGRAMS"

Another contribution to the series of editorialettes, submitted in response to invitations extended in these columns, comes from Pauline Brooks Williamson, Chief of the School Health Bureau, Welfare Division, Metropolitan Life Insurance Company. Miss Williamson writes as follows:

Schools and colleges are being rapidly mobilized in the all out war effort. Since time is an important factor, accelerated programs are being organized to speed up education.

Accelerated classes are not for young children at any time. The rate of child growth cannot be forced without distorting lives.

Accelerated classes for students in high schools, colleges, and universities, when first introduced, were watched with concern by educators. They feared that these classes might mean superficial work on the same old formal courses planned for a past era, demanding longer hours and more strain at the expense of the students' recreation and application of other laws of health. This would have been a waste of irreplaceable man power and a distinct advantage to the enemy.

Fortunately, our best colleges and universities report a different experience. In these accelerated classes more attention is being paid to worth while activities, and improved methods of attaining immediate goals for the war effort are being used. Such courses are a boon to the students and faculty because they bring more zest to the work, and

individual and social satisfaction in contributing necessary service to the world conflict. Scientific approaches to vital problems, and efficient methods of learning are being applied to specific purposes and to more efficient and speedy development of skills needed in industry and in the armed forces. University presidents and students report that the tempo of the accelerated classes, affording opportunity for the students to work to the utmost of their capacity, when accompanied by more vigilance in following generally accepted health practices, results in improved mental, emotional, and social health and in distinct advances in education. Real joy in a worth while job well done is part of our American tradition, and along with accelerated programs our cultural heritage is being preserved. To quote Dr. Charles Seymour, President of Yale University:

"It should be noted that the Army and Navy plans provide ample opportunity for the student to acquire the fundamentals of what are called the liberal arts. If a student's interests and aptitudes lie on the academic rather than the scientific side, he is urged to pursue them in his major course. This is wise educational policy in the matter of training men how to use their minds, and it will certainly serve the essential purpose of the Army and Navy. It is equally wise educational policy for the post-war future of our nation. The things for which we fight would lose most of their value if the classical heritage of our past were lost, and if the American people were no longer trained to appreciate the beauties of art and music and the grandeur of the world's best literature. We are fighting, not merely to survive as a free, but also as a civilized people."

Health officers can throw their powerful influence toward intelligent and patriotic acceleration in medical colleges, schools of public health, as well as in teachers colleges.

(EDITORIAL NOTE: Editorialesques from other contributors will be welcomed. Choose your own subject—preferably one related to health education. Publication of submitted material is not guaranteed, though serious consideration will be given to all contributions.)

CONCERNING LETTERHEADS

As Bauer and Hull point out in the latest edition of their text book *Health Education of the Public*, many health agencies, and especially voluntary societies, have a great tendency to cover their letterheads with lists of names, committee memberships, and the like. Some letterheads carry so much data of this sort that very little space is left for correspondence. It strikes us that this is a form of "window dressing" that could very well be deleted, with the space being given to more pertinent information.

The letterhead used by *Hygeia* is a good example of how marginal space can be utilized to convey an interesting and significant message. The left-hand border of this letterhead bears the following statement:

PEOPLE DIFFER—

No two living things are alike. Physicians do not treat symptoms or diseases. They treat patients. A list of symptoms or a long case history in a letter is no basis for a positive conclusion as to what is wrong with the patient and what he ought to do about it. There is no standard dosage for drugs applicable to all patients under all circumstances. There is no standardized diet useful to all patients suffering from the same disease.

We are glad to give all the health information we possibly can, but we must decline to prescribe and treat patients by mail. Diagnosis or treatment by mail is not scientific, and can never be satisfactory—Therefore—

WE REGRET THAT WE CANNOT—

Make a diagnosis by mail:
Prescribe medical treatment by mail.
Prescribe diets for sick individuals.

Tell an inquirer whom we have never seen whether he ought or ought not to have a surgical operation.

Predict the outcome of any treatment in any patient.

This statement, being a clear exposition of the magazine's editorial policy with regard to answering health inquiries, is a time-saver in that it makes lengthy explanations unnecessary. This is important in organizations where

large volumes of correspondence are handled daily.

Letterheads of other health agencies feature timely messages at various seasons of the year such as brief statements about precautions to take against colds or pneumonia during the winter months and how to avoid vacation hazards during the summer time. Such "healthograms," as one agency terms them, are very effective and when printed in colored ink add to the letterhead's appearance. Make the most of your margins—is our tip in this connection.

MAGAZINE ARTICLES

Recent popular magazine articles on health or of medical import:

"The ABC of Tuberculosis." Joseph D. Wassersug, M.D. *The American Mercury*, October, 1942.

"Is Everyone Allergic?" Joseph G. Lee, M.D. *Parents' Magazine*, September, 1942.

JOTTINGS

Health educators have never placed much stress on the control of bedbugs for the reason that they "have not been definitely incriminated as important natural vectors of any disease." However, it now appears that bedbugs may be the source of something more serious than mere discomfort. Recent research suggests that "the bedbug is the major vector in the natural epidemiology of lymphocytic choriomeningitis." (See the *Journal of the American Medical Association*—issue of August 22, 1942—Editorial Section.) The mosquito, recently incriminated in the transmission of certain types of encephalitis, is also not without suspicion as a factor in this variety of meningitis. . . . The New York Academy of Medicine (Medical Information Bureau) and the Board of Education of the City of New York conducted an intensive course in health education for 1,500 teachers during the summer vacation season. In the Academy's assembly hall, 4 hours a day, for 10 weeks, a faculty of 30 specialists reviewed basic points in the fields of communicable diseases, nutrition, home nursing, mental hygiene, and first aid. The course was designed to equip New York City school teachers as "health wardens," to spread information to other teachers, to pupils, to parents, opening up a "second front" in health education. . . . Personal nomination for the Book-of-the-Month: *Ambassadors in White*, by Charles

Morrow Wilson, published by Henry Holt and Company, at \$3.00 per copy. Here is a wholly absorbing account of the long battle for health in the Americas as waged by Finlay, Noguchi, Reed, and Gorgas. This book contains excellent descriptions of certain tropical maladies—"maladies that may cross the barricades of the most careful sanitary inspection and gain a foothold within our own borders." The author makes clear the importance of health control measures in relation to the full utilization and development of Latin America's great resources. . . . The comparatively neglected field of social medicine (not to be confused with "socialized medicine") is to be explored and studied at Oxford University, England. An Institute of Social Medicine has been created to deal with the environmental factors that undermine physical and mental well-being. Where sociologists and public health officials are concerned with humanity in the mass, this new institute will concentrate upon the individual person in order to discover how his life may be lengthened by removing the communal causes of disability. This is a new kind of preventive medicine and the institute's work deserves attention here where we have not yet taken full cognizance of such factors as city noise and smoke, the annoyances of family life, monotonous work, economic insecurity, and worry as causes of ill health. . . . A recent issue of the *Monthly Bulletin* of the North Carolina State Department of Health carries on the front cover a likeness of Dr. Milton J. Rosenau, Head of the Department of Public Health and Preventive Medicine at the

University of North Carolina. We heartily endorse the *Bulletin's* editorial comment that "Dr. Rosenau has done more for health education than perhaps any other person." . . . The New York State Department of Health has issued a number of publicity items on home and farm safety for the use of health officers. The material includes a series of news releases and suggestions for radio talks on important phases of the subject. Coming from an established safety agency this material would be considered routine, but it is exceptional; if not unique, to see it issued by a state department of health—marking as it does an important new development in the public health field. . . . A number of health films of exceptional quality have been issued by the Film Section of the British Information Services, 30 Rockefeller Plaza, New York, N. Y. Included among the subjects are pictures on blood transfusion, health during wartime, plastic surgery, the education of the blind, physical fitness, and diphtheria prevention. Information concerning these pictures is available from the agency at the address given above. . . . Some time ago we learned that Dr. H. E. Kleinschmidt had retired from the staff of the National Tuberculosis Association, and was enjoying a well earned rest. We join with others in hoping that we may soon again see him back in harness and in the front ranks of public health education during the war period. The times are too critical to afford the permanent loss of the unique skills and vast experience which Dr. Kleinschmidt possesses and which are so pertinent to the needs of the moment.

BOOKS AND REPORTS

School Health Problems — By *Dorothy B. Nyswander, Ph.D.* New York: *The Commonwealth Fund*, 1942. 377 pp. Price, \$2.00.

If you were making a list of "must" reading for health officers, school superintendents, and directors of school health service, you would include this book. It presents the outcome and details of a four year intensive study of school health service in New York City dealing with "the effective utilization of organized effort for the better health of school children." The book makes a clear presentation of an important study by an able research staff under the direction of an impressive advisory committee.

The Department of Health and the Board of Education of New York City, as well as the professional people immediately concerned with the study, are to be congratulated upon the frank, scientific, and pioneering methods with which they undertook a study of administrative problems. They have studied the work of the school physician, the teacher, and the nurse. They have investigated such specific problems as follow-up, the testing of visual acuity, the testing for loss of hearing, obtaining dental care, the supervision of cardiac children, the relationship of private physicians to the school health program, and staff education.

In respect to all of these items the various elements of strength and weakness in the New York program have been analyzed. Many constructive procedures and technics in school health administration have been devised, tested, and recommended. The applications of the study are in no way restricted to New York City. The study represents the "laboratory" method

applied to school health administration. It deals with problems which are common to most school systems. It shows us how we can evaluate our present school health programs, and gives us many concrete suggestions for improving it.

C. E. TURNER

So Build We—By *Mary S. Gardner.* New York: *Macmillan*, 1942. 223 pp. Price, \$2.25.

So Build We presents in fictional form a series of episodes in the life of a public health nurse executive. Miss Mary Melton is just one of any number of nurses who come face to face with professional and human problems in their everyday work.

The story is alive and appealing. Out of her wide experience, the author gives much sound advice, but she succeeds in conveying this advice through a thoroughly entertaining story. Her extraordinarily fine sense of humor has not only contributed to the quality of this book, but it must also have been a strong factor in her successful career.

The book will be read by nurses who know Miss Gardner, with the feeling that they have had a personal conference with her and have benefited by her human, realistic analysis of fundamental social situations. Those who have not had the privilege of Miss Gardner's personal influence will feel the inspiration of a great leader and have the desire to emulate the thoroughly fine, unselfish devotion to service personified in the characters through whom she expresses her philosophy.

This book is a real contribution to public health nursing literature. It will serve a purpose which no other book on the subject meets. It should be read by student nurses, public health nurses,

physicians, health officers and lay persons interested in community service, and if one has no specialized interest in social programs it is, at any rate, a delightful novel. AMELIA H. GRANT

Chemistry and Physiology of the Vitamins—By H. R. Rosenberg. *New York: Interscience Publishing Company, 1942.* 674 pp. Price, \$12.00.

This book with 674 pages and almost 3,000 references is probably the most complete record of the work done in the field of vitamins up to 1942. The subject matter is systematically arranged and it is critically and comprehensively appraised from chemical, physiological, nutritional, and industrial points of view. Methods of preparation of the better known vitamins and the procedures for their determination by chemical and biological means are outlined in a clear, if somewhat abbreviated, form.

The discussion of the essential fatty acids, chlorine and related compounds, and the essential organic sulfur-containing compounds, which the author groups as the "vitagens," is appended to the main section of the book. The brief treatment given to the sulfur-containing amino acids, however, does not add to the excellence of the book. For instance, contrary to facts the author states that "there is actually ample experimental evidence that cysteine is synthesized in the organism from methionine without cleavage of the sulfur linkage." Actually no such direct evidence is admitted by the authors to whom Dr. Rosenberg refers in support of his statement.

In this age of high-pressure publicity, and in view of the somewhat confused state of vitamin affairs, Dr. Rosenberg's book should be heaven sent to teachers of biochemistry, nutritionists, clinicians, and even to vitamin-plagued laymen. It is neither dogmatic nor is it simply a historical survey of the field. The

author plainly states, after a critical survey of each topic, what could be considered as known, established, or doubtful, pending further work.

The book will undoubtedly undergo several editions in view of the dynamic state of the field of vitamins. The general plan of the work, however, is such that it will not grow out of date soon. In any case, the relatively low cost of the book is well worth the return.

J. A. STEKOL

The Collected Reprints of The National Foundation for Infantile Paralysis — 1941 — Vol. II — *New York: National Foundation for Infantile Paralysis, 1942.*

This thick volume, containing 57 reprints, is about twice the size of Vol. I, which also represented the published results of investigations which have been supported by grants from the National Foundation for Infantile Paralysis. As such, it becomes in some ways an annual report of the research activities supported by this Foundation; but the book performs other functions too, *viz.*: it is a fairly complete report of the recent (1941) advances in knowledge, arranged chronologically as of the date of publication, in the field of poliomyelitis, and it can be used as a handy reference volume for the bookshelves of anyone engaged in studying or writing on the subject of poliomyelitis, who wants to have certain of his current (1941) reprints under one cover. One can find in these pages most of the important trends regarding laboratory experimentation in this disease; in other words, what North American representatives of the medical profession have been doing about poliomyelitis, and what they have been thinking about, during the past year. This last statement deserves some qualification, for not all the laboratories and not all the groups of workers engaged in investigations on poliomyelitis in this country

and in Canada are supported by this Foundation, although the great majority of them are. If, for instance, one were to add the reprints of Howe and Bodian, of the Johns Hopkins Medical School, and the reprints of Aycock, of the Harvard Medical School, he would have a very representative annual list of the work done in this country.

As to the quality and caliber of the research which is reported in these papers, the reader can judge for himself. One might find half a dozen papers in the series which seem to be only remotely related to the field of poliomyelitis—such as: "The Effect of Quinine on the Metabolism of Fasting Dogs and Patients with Creatinuria," or "A Modification of Mallory's Phosphotungstic Acid-hematoxylin Stain for Formaldehyde-fixed Tissues." These titles may provoke a certain amount of pursing of the lips, but on closer study it will be found that they represent papers which are part of a series of studies which seem to have as their eventual aim something to do with poliomyelitis. On the other hand, there are at least some papers in this series which have a great deal to do with poliomyelitis.

It may be too soon to judge the actual significance of this most recent work, but to the reviewer it would seem that the advances made and reported in 1941, are above those of the average year. There are the excellent studies by Sabin and Ward, in which human autopsy material has been carefully tested for virus from a large series of fatal human cases, indicating as no other studies have ever done how there are *two* major sites of predilection in the human body (in the late stages of the disease) for the virus; namely, the central nervous system, and the lower bowel. There is the first (rather ultra-cautious) paper tending to voice acceptance of the Kenny treatment in this country—the harbinger of many papers to come. There is a series of papers

from the Hooper Foundation on equine encephalomyelitis of the Western type. This disease, like poliomyelitis, is a virus infection of the central nervous system, which is prone to occur in the summer; and the (1941) discoveries of Hammon, Howitt, and others, are included in this volume. Among these papers on encephalitis are reports of finding the virus of this disease in mosquitoes captured in the field, and of evidences of immunity (or at least neutralizing antibodies) in the blood of a great variety of species besides those of the horse and man. Such new facts yield a fund of information about a disease which may in all probability be closely related to poliomyelitis.

There is also an interesting feature with regard to the three papers dealing with the discoveries of the virus of poliomyelitis in flies captured during epidemic times. These three papers appeared within 60 days of one another, representing a rather striking example of a finding which was ready to be made.

The reviewer trusts that he voices the sentiments of many readers by stating that he hopes that these annual volumes may continue to appear. JOHN R. PAUL

The Science of Health — By Florence L. Meredith, B.Sc., M.D. (2nd ed. of Twelve Hours of Hygiene). Philadelphia: Blakiston, 1942. 427 pp. Price, \$2.50.

This is the second edition of a book previously entitled "Twelve Hours of Hygiene." It is intended for use as a textbook in "one-hour-one-semester" college courses in hygiene. The contents relate primarily to personal hygiene, although certain phases of vital statistics are dealt with in the introduction. An appreciation of the importance of community hygiene is omitted. Scientific explanations are given as far as possible, but much that must be included in a textbook of this character rests on belief. The contents are presented in great

detail, parentheses are used to excess, and awkwardly constructed sentences appear. "If no sterile goods are at hand, a clean handkerchief, or any soft, clean cloth may be ironed until slightly scorched and the scorched side, untouched by the hands or anything else after ironed, may be applied to a wound."

The author takes the view that much may be accomplished in college courses in hygiene through use of a comprehensive text, and she has made a special effort "to give facts usable by the student in making his own decisions in whatever circumstances he finds himself." This is an ambitious undertaking and accounts for the emphasis on details. Those subscribing to a similar teaching philosophy will be interested.

ADOLPH WEINZIRL

W. K. Kellogg Foundation: The First Eleven Years—*Battle Creek, Mich.: Published by Trustees of the W. K. Kellogg Foundation, 1942. 217 pp.*

Readers of annual reports will have a unique experience in this report of the first eleven years of the W. K. Kellogg Foundation, relating the story of the Michigan Community Health Project and other ventures of this Foundation. It is a commendably forthright and readable account of purposes and fiscal affairs. But it is more than that.

An outstanding feature of the volume is the pictorial review of the work done under Foundation auspices in seven rural counties of Michigan. This attempt to portray the underlying principles of the work through pictures and their titles is eminently successful. As illustrations of the way in which a community can be organized for health, these pictures should be of service in showing the student of administrative practice how the educational approach can be used in all sorts of circumstances. It can serve as a reference work in a

variety of courses. If a student has any imagination it will be fired.

This report of the W. K. Kellogg Foundation belongs in the top flight group of outstanding foundation documents, along with annual volumes of the Commonwealth Fund and the Rockefeller Foundation, all of which have a public educational value beyond the strict limitations of the reports themselves.

REGINALD M. ATWATER

Personal and Community Health—By C. E. Turner. (6th ed.) St. Louis: Mosby, 1942. 652 pp. Price, \$3.50.

This text is planned for instruction of groups at the various college levels. The sixth edition contains 652 pages distributed as follows: 533 pages of discussion text arranged in 32 chapters; 78 pages reprinting the 1935 report of the committee of the American Public Health Association on the Control of Communicable Diseases; 9 pages of appendix discussing disinfection and disinfectants; 11 pages of glossary, and 20 pages of index.

It is well written and well printed, and the material is carefully selected and well balanced. The author has presented his discussions clearly and with conservative and considered judgment. The book has already won a deserved place in its field which the new sixth edition will help to maintain.

In a book which has so many fine qualities, one hesitates to comment adversely. There is one respect, however, in which the book is somewhat disappointing, namely the bibliography. It is true that a bibliography should cite the authority for statements when such citation is needed. In a text of this kind, however, it should provide suitable collateral reading wherein the student may find more extensive material than the text provides. Many of the subjects discussed are affected by recent

studies and the students rightfully expect the reference material to be reasonably recent. Of 238 references in the bibliography in which the date of publication was given, only 8 per cent were to articles published within the last five years, 92 per cent being to older literature. Forty-one per cent referred to articles published 6 to 10 years ago, and 42 per cent to those published 11 to 15 years ago. For its intended purposes, this useful book will be even more valuable if in future editions the revision extends to the bibliography.

M. E. BARNES

Tuberculosis Sanatorium Directory—By *National Tuberculosis Association, New York (1790 Broadway)*, 1942. 185 pp. Price, \$1.50.

The profession is again indebted to the National Tuberculosis Association for a comprehensive directory, the first to appear in four years. During this period the number of beds for tuberculosis in continental United States has increased to 97,726, a gain of 12 per cent, all of which has been among tax supported institutions. Private and semi-private institutions have shown a loss of 5 per cent in beds. In addition to the geographical list there are lists of federal sanatoria and hospitals, a list of mental hospitals making special provision for tuberculosis, and of penal institutions similarly making provisions. Tables show the number of institutions by states, the provision for children by states, the provision for Negroes by states, and the ratio of beds to deaths from tuberculosis by states. Altogether it is a very comprehensive and up-to-date directory.

REGINALD M. ATWATER

Nursing: A Community Health Service—By *Amelia. Howe Grant*. Philadelphia: Saunders, 1942. 277 pp. Price, \$2.50.

This book aims to meet the needs of

"graduate nurses preparing for public health nursing and for students in the basic nursing education programs of study."

The book is developed in three major units. Unit I starts with a brief review of the development and some of the present trends in the field of public health. This is followed by a discussion of public health nursing, its history, the organizations which are concerned with the administration of the service, and the major factors which characterize public health nursing as a family and community nursing service.

Unit II deals with the preparation of the nurse for effective service in this field. The importance of a good basic professional education, the programs of study in universities for the preparation of the graduate nurse in public health nursing, the qualifications for various positions as set forth by the National Organization for Public Health Nursing, and the program of staff education administered by the best public health nursing organizations are discussed carefully in this section.

In Unit III the special phases of public health nursing are reviewed as to their objectives, problems, policies of administration, nursing activities, and responsibilities.

Through *Nursing: A Community Health Service*, Miss Grant has contributed a book which will serve the needs of many groups and individuals. The instructor in the basic school of nursing will find it of value in interpreting the interrelationships between health and illness and the social factors which influence good nursing care. The graduate nurse interested in preparing herself for public health nursing will find a helpful guide in planning her preparation and a concise, yet comprehensive, survey of the major public health nursing services. The practitioner in the field will find the book of value, not only for herself, but as a

reference for lay workers who are interested in knowing more about the history, development and trends of a community service which they have long supported.

ELLEN L. BUELL

Health Conditions, New York City, by Health Center Districts and Boroughs, Five Years, from 1936 to 1940—New York: New York Tuberculosis and Health Association, 1942. 30 pp.

This handbook of health data presents recent mortality and morbidity reports in a manner to bring out areas of the city where special attention is needed as well as to give an over-all picture of vital statistics. Population changes due to natural increase and migration are analyzed, the marked variations indicating the importance of such basic data for constructive planning. With an average infant mortality rate of 34.9 in 1940, for example, the range among health districts was from 23.3 to 56.3. With an average tuberculosis mortality rate of 49, there was a range among health districts from 15 to 204, the range for boroughs being from 27 to 82. This invaluable source of basic information abounds in detailed statistical tables, is well illustrated with unusually effective charts, and continues a series which has long been valuable for administrative and teaching purposes.

IRA V. HISCOCK

Physiological Hygiene—By C. P. Hickman, Ph.D. New York: Prentice-Hall, 1942. 482 pp. Price, \$3.25.

This book is a frank effort to present modern medicine to college students. It is a miniature of almost the entire medical curriculum. No one thoroughly inured to the conventions and complexities of medicine would have had the hardihood to attempt its conception, development, parturition, and subsequent influence upon young men and women; that is, no one who had

been an active participant in the multitude of mistakes and the occasional successes which have attended medical progress.

The vital question which arises when one reads such a text is the accuracy with which the author portrays his offering to the innocents who must make it their gospel. Dr. Hickman is a Doctor of Philosophy, a zoölogist. This gives, perhaps, a certain intrepidity in approaching the entirety of human physiological experience which would be lacking in an ordinary doctor! For example, on page 161, dealing with "Circulatory Diseases," one reads "High blood pressure may run in families, and appear quite early in life." (Reviewer: This is true and very important in the examination of patients.) "This factor, however, appears to be a less common cause of arteriosclerosis than the second named." (Reviewer: *The second named* is, "wear and tear, abuse, the introduction of poisons into the system, and diseases.") "Good blood vessels may very easily acquire arteriosclerosis simply through their misuse." (Reviewer: This is emphatically untrue. No one knows how to misuse blood vessels wilfully.) "Alcoholism and syphilis are definitely known to be direct causes." (Reviewer: This is quite misleading. Alcoholism causes a wide complexity of human ills but not arteriosclerosis. Syphilis is permissible as a causative agent.)

Such criticisms may seem unduly condemnatory. There are many errors in the book, but who could write a text covering all of medicine and physiology without getting into trouble? It has one quality absent from most elementary books. Whether right or wrong, the student reader will want to know more! A textbook for college use that accomplishes such an end may be pardoned for errors incident upon too expansive a plan of presentation.

CECIL K. DRINKER

The Life of Florence Nightingale—By Sir Edward Cook. New York: Macmillan, 1942. 510 pp. Price, \$4.50.

The new edition of Sir Edward Cook's *The Life of Florence Nightingale* is peculiarly timely in view of the impetus which the present war has given to tropical medicine and to military medicine. Miss Nightingale's name is so identified with the founding of the profession of nursing that few are aware of her fundamental contributions to sanitation, military medicine, tropical medicine, medical statistics and nomenclature, and hospital construction and administration, all based upon her own experience in the military hospitals at Scutari during the Crimean War.

She was directly responsible for several inquiries into the health of the Crimean Army, the army at home, and the army in India, and contributed importantly to the findings and recommendations of the Royal Commissions appointed to deal with these matters.

She demonstrated conclusively that the medical morbidity and mortality rates among British troops at home stations, in the Crimea, and in India, were largely preventable. By the application of simple sanitary measures she greatly reduced the incidence of hospital-transmitted dysentery and typhus. She emphasized repeatedly that the one protection against cholera is sanitation.

She was responsible for the introduction of sanitation into the British Army, for the complete reorganization of the Army Medical Department and the Army Hospital system, for the establishment of the Army Medical School, and she it was who nominated the first faculty. She prepared a classification of disease and medical statistical forms which were made available to the medical department of the United States

Army at the request of the Secretary of War, during the Civil War. With ample justification she may be referred to as the mother both of military and of tropical medicine.

This biography is one which should be widely read by physicians, sanitarians, and medical students. It is readable and extensive. It is replete with direct quotations from personal letters, from the various Royal Commissions, and other original sources, which greatly enhance its historical value. A lengthy bibliography and a useful index are included.

THOMAS T. MACKIE

Psychotherapy in Medical Practice—By Maurice Levine, M.D. New York: Macmillan, 1942. 320 pp. Price, \$3.50.

This book is designed to give the general practitioner a survey of essential points dealing with the relationship of psychiatry and mental hygiene to the field of medicine. Its chapters comprise:

Common Misconceptions, Methods of Psychotherapy, Methods for the General Practitioner, Advanced Methods for the General Practitioner, Methods for the Specialist, Suicide Risks, The Study of Psychogenic Factors, The Choice of Cases, Sex and Marriage, Basic Attitudes Toward Children, The Problems of Parents and Children, and Normality and Maturity.

The writer gives clearly his views and their practical application in a common sense and readable form which should be of value to the audience for which the book is written. One hopes that the "audience" will read this book and not treat it merely as another volume to be added to their medical library.

ESTHER L. RICHARDS

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

About That Army Jaundice—Most health workers will have to listen to discussions, or their opinions will be asked, about the late and lamented outbreak of jaundice among soldiers and sailors protected with yellow fever vaccine. It is well to be armed with the truth, and here you will find it, in a circular letter issued to all military medical officers. There is editorial comment on the subject in the same issue.

ANON. The Outbreak of Jaundice in the Army. *J.A.M.A.* 120, 1:51 (Sept. 5), 1942.

Order from Administrative Chaos—War has brought into prominence the lack of a unified system for medical care in Great Britain. The time has come, this committee report insists, to prepare for an organization to deal adequately and efficiently with medical care and health needs of the whole nation. American sanitarians, living in a land where health and medical services are even more Topsy-like in their hit-or-miss growth, will find much food for cogitation in the proposals outlined by the British Society of Medical Officers of Health.

ANON. A (British) National Health Service. *Pub. Health.* 55, 12:199 (Sept.), 1942.

Raw Milk's Added Attraction—Milk even when produced under acceptable sanitary conditions frequently contains hemolytic streptococci of human origin. Should you ever need it, here is new and convincing evidence with which to confront those raw milk enthusiasts who are aware that tubercle bacilli seldom are found in market milk these days.

BEAHM, E. H. A Bacteriological Study of the Streptococci Isolated from Raw Retail Milk. *Am. J. Hyg.* 36, 2:147 (Sept.), 1942.

Repairing Air Raid Damage—Have you water troubles on your mind? Has the wartime problem of safeguarding water supply to any part of your population been placed at your doorstep? Then you'll be very greatly concerned with this excellent report from bomb-damaged Britain. Following it are a half dozen worth while papers by American writers upon our own less tragic domestic difficulties.

BERRY, H. Water Supply in War-Time London. *J. Am. Waterworks Assn.* 34, 9:1298 (Sept.), 1942.

Husbands and Wives Dying from Similar Causes—One would anticipate that spouses of husbands or wives, dying of tuberculosis, influenza, or pneumonia, also would succumb to these communicable diseases at rates greater than the normal expectation. But that the phenomenon should hold true in the case of cancer, would seem hard to explain. Though no explanation is offered, another study (of a nation-wide sampling) confirms the findings of an earlier review of vital statistics of a single county.

CIOCCO, A. Data on the Concurrence of Death from Tuberculosis, Influenza and Pneumonia, Cancer, and Heart Diseases among Husbands and Wives. *Pub. Health Rep.* 57, 36:1333 (Sept. 4), 1942.

Health Services in Boom Towns—Built, or building, are 435,000 dwelling units to accommodate 1½ million tenants, a half-million of whom will be engaged in war work. The character of the sanitary, medical, nursing, and dental services furnished this group of essential workers will have a direct and decided effect upon the outcome of this war. Some of the problems incident to

supplying these health services are studied.

FREEDMAN, D. K. Health Problems in War Housing. J.A.M.A. 120, 1:9 (Sept. 5), 1942.

Mothers and Babies in the War—Care of expectant mothers among evacuees and wartime nurseries for the children of mothers engaged in war work are subjects that may some day arise to plague American administrators. Here then are three papers upon British experience.

GODDER, G. E., *et al.* Experiences in the Reception of Evacuee Expectant Mothers (and two related papers). Pub. Health. 55, 11:188 (Aug.), 1942.

School Children in War-Time—Hardly a school child but has been affected by the war. Homes have been disrupted, insanitary living conditions have increased, tensions have developed, and the schools find themselves out in front bearing the impact of these conditions. What the school nurse can do about this war-time problem is discussed.

GROUT, R. E. Nurse in War-Time School Health Program. Pub. Health Nurs. 34, 9:477 (Sept.), 1942.

Why Must They Call It "Mess"?—A recent *New Yorker* illustration portrays an inquisitive old lady asking a surprised soldier how many greens he is fed each day. Perhaps you, as an "expert" in all matters of health, are asked about the army and navy rations by worried mothers and dubious fathers of boys in the service. Well, here is the factual material which will enable you to answer them intelligently.

HOWE, P. E. Nutritional Aspects of Feeding an Army (and) BROWN, E. W. Nutritional Aspects of Feeding in the United States Navy. J.A.M.A. 120, 2:93 (Sept. 12), 1942.

Anent Grandma's Chronic Bronchitis—All case finding methods should be applied vigorously to the search for tuberculosis among older people. If

you want evidence that there are still many undetected cases of chronically infectious tuberculosis in the higher age groups you'll find it in this paper.

MILLER, R. E., and HENDERSON, B. Undiagnosed Pulmonary Tuberculosis in Elderly Persons. Am. Rev. Tuberc. 46, 2:164 (Aug.), 1942.

In Our War against Influenza—Experimentally, it is provable that both ultra-violet radiation and propylene glycol vapor will prevent certain airborne infections with influenza A virus. Experimentally, it has been found that highly concentrated egg-fluid virus vaccine will give some protection against influenza A infection. Immune serum also protects, under the controlled conditions described. Are we, therefore, ready to meet the next pandemic of influenza? Certainly some weapons are available. Time will determine the completeness of our armamentarium.

STOKES, J., JR., and HENLE, W. Studies on Methods of Prevention of Epidemic Influenza. J.A.M.A. 120, 1:16 (Sept. 5), 1942.

About Blood Banks—If you are making your blood donations every 8 weeks, as you should—assuming that you're healthy and under age 60—you'll be doubly interested in this report upon the conduct of the blood banks. If you haven't yet begun your regular "deposits" in this most important of all banks you'll begin as soon as you read this reassuring paper.

TAYLOR, E. S. Procurement of Blood for the Armed Forces. J.A.M.A. 120, 2:119 (Sept. 12), 1942.

Criminal Negligence Department—Just as a reminder that children still die needlessly of diphtheria, this report is worth noting. Of the diphtheria cases admitted in three years to the Los Angeles County General Hospital, 36 went to their death. What complications they died of and why is the point of this study.

TOGASAKI, Y., *et al.* Treatment, Complica-

tions and Deaths in 753 Cases of Clinical Diphtheria. *Am. J. Med. Sci.* 204, 2:218 (Aug.), 1942.

Out from the Rut—Effective use of the limited professional services available for school health supervision is a subject which should be of interest to health workers even in communities where the problem is one solely for the educational authorities. This story of the Astoria (N. Y.), School Health Study drives home the point that precious professional services must not be wasted upon outmoded practices.

WHEATLEY, G. M. Health for Tomorrow's School Child. *Pub. Health Nurs.* 34, 9:483 (Sept.), 1942.

An Old Problem in a New Setting—Some of the inherent difficulties in following up persons rejected by draft boards and the army doctors because of tuberculous lesions are enumerated.

It is pointed out that this is potentially the one greatest case finding opportunity in the history of the disease.

WILLIAMS, C. J. The Tuberculous Registrant. *Am. J. Nurs.* 42, 9:989 (Sept.), 1942.

Alteram Partem, Audire—Although there is a direct and statistically significant increase in tuberculosis among the husbands or wives and brothers or sisters, of persons dying of tuberculosis the negative findings must not be overlooked: 83 per cent of the spouses and 86 per cent of the siblings did not die of tuberculosis though exposed for many years. Quite evidently there is a constitutional element as well as the factors of specific infection and social environment which influences the spread of tuberculosis.

WOLFF, G., and Ciocco, A. Infection, Social Environment, and Heredity in Tuberculosis. *Am. Rev. Tuberc.* 46, 2:142 (Aug.), 1942.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

U. S. CIVIL SERVICE COMMISSION

The Commission has announced again its need for public health nursing consultants in war work. The new announcement now provides for 5 grades and for appointments in the Children's Bureau, Department of Labor, U. S. Public Health Service, and Federal Security Agency. Salaries range from \$2,600 to \$5,600 a year. No age limits have been set. Positions exist both in the United States and foreign countries. War service appointments will be made to extend generally for the duration of the war and no longer than 6 months afterward. Duties are to carry out, in accordance with the rank of the position, nursing or nursing education programs; and to act in advisory capacity to Federal agencies, or to State, County, and municipal organizations.

There will be no written test, qualifications being judged solely from review of experience, education, and training of applicants. Persons applying must have completed a 4 year course in a recognized college and 1 year's special program of study in public health nursing approved by the National Organization for Public Health Nursing; must also have graduated from an accredited school of nursing affiliated with a hospital having a daily average of 100 or more bed patients; be registered nurses in a state or territory of the United States or the District of Columbia, and have had appropriate general public health nursing supervisory experience. Additional credit given for completion of approved college course in statistical analysis, public health nursing, supervision, social hygiene, tuberculosis control and maternity, pediatric or orthopedic nursing; also for certain appropriate experience as instructor, consultant, or investigator.

For positions in Children's Bureau

additional progressive experience in specialized fields of maternal or child health is required for the top grade and may be substituted for part of the general experience prescribed for the other grades.

Applications must be filed with the U. S. Civil Service Commission, Washington, D. C., and will be accepted until the needs of the service have been met. Forms may be obtained direct from the Commission or at any first or second class post office.

Merit System Council, Oregon State Board of Health and Crippled Children's Division, has announced merit examinations in practically all professional public health fields, including Health Officers, Nurses, Sanitary Engineers, Laboratory Workers, Vital Statisticians, Consultants in the fields of Health Education, Hearing and Vision, Nutrition, Oral Health and Physiotherapy. Two clerical positions, Fiscal Worker and Administrative Clerk are included in this list as is also the position of Merit System Personnel Technician.

Interested persons may get full particulars regarding the positions and examinations by writing H. J. Sears, Merit System Supervisor, P. O. Box 88, Portland, Ore.

The Indiana State Personnel Division, 141 South Meridian Street, Indianapolis, announces that applications may be filed at any time until further notice for the following positions:

Orthopedic Nursing Consultant I (women only) ..	\$150-200 mo.
Physician I (General)	165-250 mo.
Physician II (General)	250-325 mo.
Physician II (Tuberculosis)	250-325 mo.
Physician I (Psychiatric) ..	185-265 mo.
Physician II (Psychiatric) ..	250-325 mo.
Local Public Health Director	300-360 mo.

POSITIONS AVAILABLE

Western state department of health will consider applications from physicians to fill four existing vacancies among county health officers, one vacancy in venereal disease control and positions as

laboratory technicians. Write Box S, Employment Service, A.P.H.A.

Physician with either public health training or experience in local health de-

partment administration to serve as health director in a county or district health department in midwestern state. Salaries vary from \$4,000 to 4,500 with \$500 to \$600 travel, flat rate. These are well established health departments. Write Box T, Employment Service, A.P.H.A.

County Public Health Nurses for New Mexico. Must have 4 months' postgraduate instruction under one of the recognized public health nursing courses and 1 year's experience. Must drive and have a car. Address inquiry to State Health Department, Santa Fe, N. M.

Wanted: Supervisor of generalized public health nursing staff of 6 to 8 nurses. Beginning salary \$175 per month, with opportunity for increase to \$220 and travel expenses. Must be high school graduate, graduate of hospital of 100 beds, and must have at least 1 year's postgraduate study in public health nursing at a recognized institution, and 2 years' experience in general public health nursing under qualified supervision. Apply Box L, Employment Service, A.P.H.A.

Southern state department of health seeks several obstetric and pediatric consultants, requiring a minimum of a year's residency in a specialty, immunity to draft, and preferably training in public health. Men and women are eligible. Salary \$300 per month plus travel. Apply Box C, Employment Service, A.P.H.A.

Bacteriologist with Ph.D. or equivalent and teaching experience wanted in western state university. Must be immune to military service call. Salary about \$2,500. Write Box A, Employment Service, A.P.H.A.

Two physicians, immediate appointment, full-time venereal disease clinician conduct several small clinics rotating schedule. Experience preferred. Salary \$3,000 to \$3,600 plus actual expense not to exceed \$1,200. Write State Health Department, Santa Fe, New Mexico.

Wanted: Chemical or Ceramic Engineer or Geologist for Occupational Disease work, Division of Industrial Hygiene, State Board of Health, Raleigh, N. C.

THE AMERICAN RED CROSS NEEDS EDUCATORS

The American Red Cross will employ hundreds of social welfare workers and educators before January, 1943. These new employees will perform Red Cross services to the military units both in this country and with the task forces abroad.

Red Cross workers give counsel to the men in the armed forces about their personal and family problems, plan and organize recreational activities. They interpret Red Cross service to the military authorities. They act, to quote U. S. Army regulations, "in matters of voluntary relief and in accord with the military and naval authorities as a medium of communication between the people of the United States of America and their Army and Navy."

New professional employees needed include:

Men—Field directors, to serve at the military and naval centers here and abroad to counsel and advise men in the service regarding personal and family problems.

Men and Women—Club directors, program directors, staff assistants to operate clubs in leave areas overseas, some who qualify through executive or administrative experience, others by experience comparable to the operation of a large community center, and still others who qualify through recreation training and experience.

Men—Assistant field directors for recreation, to serve with the task forces overseas, qualified to plan, organize, and promote recreational activities such as sports, games, social recreation, entertainments, arts and crafts, music, dramatics, and game rooms.

Women—Medical and psychiatric social workers, case workers and recreation specialists in military and naval hospitals both here and abroad.

Men and women assigned to the service in this country will receive from \$135 to \$200 per month; those stationed outside the United States receive from \$150 to \$275 plus an additional \$50 per month maintenance allowance in military centers and full maintenance in club work. Uniforms are provided. Those assigned abroad are also provided with certain insurance protection.

Those interested in receiving further information or in making application for a position in the American Red Cross Services to the Armed Forces program should communicate with: Personnel Service, National Headquarters, American Red Cross, Washington, D. C.

Those interested in a position within continental United States only should apply to the nearest Red Cross area office. They are as follows:

North Atlantic Area, 300 Fourth Avenue, New York, N. Y.
 Eastern Area, 615 N. St. Asaph Street, Alexandria, Va.
 Midwestern Area, 1769 Washington Avenue, St. Louis, Mo.
 Pacific Area, Civic Auditorium, San Francisco, Calif.

THE AMERICAN NATIONAL RED CROSS
 WASHINGTON, D. C.

MEDICAL OFFICERS NEEDED—TENNESSEE VALLEY AUTHORITY

The Tennessee Valley Authority is in urgent need of medical officers who are not eligible for military service and who are willing to accept assignments to war industrial activities (construction, manufacture of war chemicals and manufacture of hydroelectric power) as their participation in the all out war effort. Responsibilities include physical examinations, industrial hygiene, care of injuries, medical care to families in remote construction areas and general public health responsibilities in construction camps and villages.

Salary ranges from \$3,200 to \$4,200 per annum with opportunity for promotion.

For further information write to Dr. E. L. Bishop, Director of Health, Tennessee Valley Authority, Chattanooga, Tennessee, or to the Personnel Department, Tennessee Valley Authority, Knoxville, Tenn.

Physician, man or woman, as director of division of maternal, child and school hygiene in southern city department of health. Woman physician with pediatric training preferred, public health experience not essential. To operate prenatal, infant and preschool clinics and promote school health program. Salary commensurate with ability and qualifications of applicant. Apply Box J, Employment Service, A.P.H.A.

The New Mexico State Department of Public Health will consider applications for the position of obstetrical consultant, Maternal and Child Health Division. Address inquiries to the State Department of Public Health, Santa Fe, N. M.

Public Health Engineer and director of Division of Sanitation of a city and county health unit; population 145,000 in the midwest. Salary, \$3,180 and travel allowance. Box E, Employment Service, A.P.H.A.

The Alaska Merit System announces the following positions:

<i>Position</i>	<i>Salary per month</i>
Assistant Commissioner of Health.....	\$500 to \$625
Maternal and Child Health Director.....	380 to 455
Director, Division of Public Health Engineering.....	290 to 335
Sanitarian, Senior Grade.....	215 to 245
Sanitarian.....	185 to 215
Bacteriologist, Senior Grade.....	290 to 335
Bacteriologist, Junior Grade.....	215 to 245
Laboratory Technician.....	185 to 215
Public Health Nurse.....	185 to 215

Appointments are being made on a provisional basis with examinations following when the staff is more adequately completed.

Apply to W. H. Matthews, Jr., Alaska Merit System, Box 201, Juneau, Alaska.

POSITIONS WANTED

ADMINISTRATIVE

Teaching or administrative position desired by physician, aged 48. Experienced teacher in preventive medicine and public health, now employed at prominent medical school; 20 years' experience in municipal health administration and epidemiology. A-491

Physician with 25 years' full-time experience in public health administration is

available for immediate appointment. Moderately hard of hearing; otherwise fully able. Salary \$4,500 or better. A-497

Physician, M.D., C.P.H., aged 47, seeks position in administrative work. Experienced in venereal disease control and industrial medicine. A-485

Physician, aged 47, M.D., Creighton

University, M.S.P.H., Michigan, experienced in school health and as director of county health unit, seeks position as administrator in state or local health department. A-498

Physician with 8 years' experience desires public health position preferably in urban locality. Age 45. Available now. A-502

WOMEN PHYSICIANS TRAINED IN PUBLIC HEALTH

Woman, aged 34, M.D., University of Basle, Switzerland, M.S.P.H., DeLamar Institute, Columbia University. U. S. citizen. Excellent references. Especially interested in industrial hygiene. A-493

Woman, aged 41, M.D., Columbia University, M.S.P.H., DeLamar Institute, experienced in epidemiology and research, seeks position offering administration experience. A-494

Woman physician, M.D., Rush, M.P.H., Michigan, 13 years' experience in school medical service and administrative county health unit, seeks administrative position. New York area preferred. A-500

Woman physician, aged 29, M.D. Women's Medical, M.P.H. Johns Hopkins. Specially interested in industrial medicine and public health administration. Has had residency in tuberculosis. A-501

HEALTH EDUCATION

Woman with master's degree in health education, 12 years' successful experience in public school and college teaching, administration and research. Will consider

position in normal school, public schools, or in official or nonofficial health agencies. Prefers South or East. Available at once. H-501

INDUSTRIAL HYGIENE

Industrial hygiene chemist. Experienced in sampling, analysis of toxic industrial gases and fumes; petrographic dust analysis; dust counting; general toxicological analysis; chemical microscopy; also experienced in making industrial hygiene surveys, with knowledge of German, French, and Spanish. Six years' experience. Desires position. I-457

LABORATORY

Man, aged 28, A.B., M.S. in animal parasitology, Ph.D. in human parasitology and tropical diseases. Two years' experience in charge of parasitological diagnosis and research in state laboratory. Research publications; teaching experience. Desires teaching position in university with opportunity to do research. L-463

Physician, B.S., M.D., 17 years' experience as director of public health laboratory, desires similar position or as administrator of division of an aggressive state health department. Experience covers investigational and control activities on water, several types of foods as chemist, and bacteriologist and serologist in syphilis and enteric diseases. L-465

MISCELLANEOUS

Public Health Nurse with M.A. degree wishes position in health supervision and teaching in college or public school. West preferred. M-452

NEWS FROM THE FIELD

FOR OUR CHILDREN IN WARTIME

A Program of State Action

Adopted August 28, 1942, by the Children's Bureau Commission on Children in Wartime in consultation with the Office of Defense Health and Welfare Services and the Office of Civilian Defense

CHILDREN are the strength of the nation. In war as in peace, their welfare is of primary importance to the nation, to states, to local communities, and, above all, to parents.

Certain nation-wide needs must be met through nation-wide action, with the participation of federal, state, and local governments, and citizens' groups. Upon the states rests the chief responsibility for the provision of legal safeguards and administrative measures necessary to assure security and opportunity for every child.

The Children's Charter in Wartime calls upon all citizens as a wartime responsibility to guard children from injury in danger zones; to protect children from neglect, exploitation, and undue strain in defense areas; to strengthen the home life of children whose parents are mobilized for war or war production; and to conserve, equip, and free children to take their part in democracy.

The same emergency needs do not exist in every state or in all communities of the same state. One state or community must give first attention to protection of children in danger zones and advance planning for evacuation; in another, day care of children of mothers employed in war industries may be the most urgent immediate need; and in another, the welfare of children in "boom" towns and trailer camps.

The specific aspects of child life most in need of attention under wartime conditions must be determined state by state and community by community.

Certain problems, however, are so closely related to the war situation that nation-wide measures are required, developed through state and local action, with federal participation when necessary.

A. The Program

In every state a program of action FOR OUR CHILDREN IN WARTIME should include measures which will assure:

1. Health service and medical and dental care for mothers and for children, including boys and girls in the age groups that may soon be called upon for war production or military service, with special provision as needed for wives and children of service men and war workers. These services should be so organized as to overcome or compensate for overcrowding of existing health facilities, shortages in medical and nursing personnel, and difficulties in transportation.
2. Adequate nourishing food for all children during the period of rising costs of living and rationing of food supplies, through such means as nutrition education, school lunches, and low-cost milk.
3. Protection of children in danger zones, including provision for their safety in the event of enemy attack; measures for emergency care following attack; and preparation through officially established evacuation authorities for evacuation and reception care, if necessary.

4. Day care for children of mothers whose employment is essential to the war program.
5. Special assistance programs as required to meet wartime needs of children in their own homes, and adjustment of public-assistance measures to meet problems due to rising cost of living, migration, and separation of families.
6. Community child welfare and other social services that will conserve home life for children and safeguard them from neglect and juvenile delinquency resulting from wartime conditions, and provide appropriate care for unmarried mothers and their children.
7. Adequate provision for the care of children who because of war conditions must be separated from their families.
8. Opportunities for recreation and other experiences in home and community life that will help children overcome wartime strain and insecurity; and provision for mental health services to help children and parents make the adjustments required by war conditions.
9. Full school attendance and school opportunity for every child, with particular emphasis on overcoming or compensating for shortages of schools and teachers where they exist, and with adjustments as necessary to conform with child labor and youth employment policies.
10. Meeting the man power needs of the nation for participation of young people in war production, having due regard for conservation of health and educational opportunity for youth and in accordance with the following principles:
 - (1) No child under 14 years of age a part of the hired labor force
 - (2) None under 16 employed in manufacturing or mining occupations
 - (3) None between 14 and 16 employed in other occupations that involve release from school or readjustment of school programs unless it has been determined that labor shortages cannot be met otherwise
 - (4) Guidance of youth 16 to 18 years of age whose work is essential to the war effort into occupations suited to their age and capacity, in which they can make the greatest contribution with the least hazard to their own health and safety

B. Procedure for Carrying Out the Program

The following steps will be necessary

to put into operation a program of action **FOR OUR CHILDREN IN WARTIME:**

I. Organization—

1. Fixing responsibility for planning, coordination, and leadership on some representative state group. Wherever practicable this group should be a committee or subcommittee of the council of defense, whose work should be properly related to the work of other defense council committees including those dealing with emergency and protective measures.
2. Inclusion in the state committee of representatives of state departments of welfare, health, education, and labor, and of state-wide organizations concerned with children; especially, representatives of active State White House Conference committees and other groups having a similarly broad purpose, with provision for full coöperation with such groups.
3. Organization of a representative local committee, when practicable as part of the local defense council.

II. Putting the program into action

1. Review of wartime needs of children and existing resources for meeting those needs, with special consideration of the 10 points listed under section A.
2. Development of state and community services adequate to meet the wartime needs of children with such financial assistance from the state or the federal government as may be required. The following measures will be necessary to achieve this objective:
 - (a) State legislation as needed to provide an adequate legal basis for wartime services for children.
 - (b) Review of adequacy of funds available from federal, state, and local sources, public and private, and securing of such additional funds as may be required.
 - (c) Review of administrative and personnel problems of state and local agencies responsible for services to children and families, and support of plans for strengthening the work of these agencies and developing closer coöordination of agency programs.
 - (d) Assistance in developing and carrying out plans for recruitment and training of additional personnel, both professional and volunteer, as required.

"PROFESSIONAL NURSING AND AUXILIARY SERVICES"

A new pamphlet with the above title covering preparation for all types of nursing services in concise form and prepared by the Nursing Information Bureau of the American Nurses' Association, has just been released.

Emphasis is placed on preparation for professional nursing and on the opportunities created by the war and its probable aftermath. Tables showing the wide variety of positions open to nurses as they advance in preparation and experience, and indicating the salaries which the various positions may command is a unique feature of the publication. A section on auxiliary nursing covers positions outside of professional nursing for persons working in civilian hospitals, clinics, dispensaries, or elsewhere as volunteer nurses' aides.

The pamphlet will be of interest to college and high school counsellors in helping young people to plan their future and to young nurses on the threshold of their careers. It may be obtained from the Nursing Information Bureau, American Nurses' Association, 1790 Broadway, New York, N. Y., at 25c.

INSTITUTE ON PERSONALITY DEVELOPMENT

The Progressive Education Association, New York, N. Y., has announced the academic schedule for the year 1942-1943 of the Institute on Personality Development. According to the Association, the purpose of the Institute is to provide advanced training in guidance and mental hygiene for workers in education and the related fields of pediatrics, social work, and school health. An informal forum is provided where professional workers from various disciplines can exchange their experiences and advance their understanding and appreciation of those distinct specialties which lie outside their respective fields

but which deal with aspects of human growth and development. The group is limited to men and women who have had successful experience as teachers, school administrators, school psychologists, school health workers, pediatricians, psychiatrists, child guidance workers, or social workers. A bulletin of information may be obtained by addressing the Executive Secretary, 17 East 96th Street, New York, N. Y.

Among the Board of Trustees of the Institute are included Caroline B. Zachry, Ph.D., Leona Baumgartner, M.D., Frank J. O'Brien, M.D.; among the Leaders and Consultants, Benjamin Spock, M.D., Milton J. E. Senn, M.D., Mary Shattuck Fisher, Ph.D., Martha Eliot, M.D., Helen Merrell Lynd, Margaret Mahler, M.D., and George M. Wheatley, M.D.

PAN AMERICAN SANITARY CONFERENCE IN RIO

The Eleventh Pan American Sanitary Conference was held during September in Rio De Janiero, with representation from most of the American republics. Hugh S. Cumming, M.D., was reelected Director of the Pan American Sanitary Bureau.

Among those in attendance from the United States were Thomas Parran, M.D., Surgeon General, U. S. Public Health Service, Washington, and Abel Wolman, Dr.Eng., Professor of Sanitary Engineering at Johns Hopkins School of Hygiene and Public Health, Baltimore.

OIL SHORTAGES COMPLICATE CUBA'S SANITATION

The press on September 18 carried dispatches from Havana indicating that the shortage of oil has prevented the burning of large quantities of garbage with resulting increase in the number of flies. It was said that lack of petroleum also has halted customary measures against mosquitoes, and that the collection of garbage was difficult be-

cause of the lack of tires and gasoline.

It was said that an infantile paralysis epidemic now current was suspected of having relationship with these sanitary nuisances.

STANDARD OF ALLOWABLE CONCENTRATIONS OF MANGANESE

The American Standards Association, New York, N. Y., has announced the completion and approval of the American War Standard of Allowable Concentration of Manganese—Z37. 6—1942. This standard has been set up through the activities of A.S.A. Committee on Toxic Dusts and Gases. A standard for cadmium, Z37. 5—1941, was the first in the series and the report on manganese is the second. The standard was prepared by the staff of the U. S. Public Health Service and was reviewed by the A.S.A. committee. It will be effective during the war period, after which it will be reviewed by the A.S.A. committee and either withdrawn or revised if necessary and reapproved. The representative of the American Public Health Association on the responsible committee has been J. J. Bloomfield, Chief of the States Relations Section, National Institute of Health. William P. Yant has been chairman of the committee.

DR. WALTER BROWN APPOINTED PROFESSOR AT BERKELEY

The appointment of Dr. Walter H. Brown of Stanford University as Chairman of the Department of Hygiene at the University of California, Berkeley, has been announced. According to *Western Public Health*, Dr. Brown agreed to change his affiliation from Stanford, where he has taught for the past 15 years, to the University of California with the express understanding that his services were needed to prepare the way for a school of public health.

Three months ago the Northern California Public Health Association appointed a committee for the establish-

ment of a school of public health on the West Coast. Members of the committee included Fred T. Foard, M.D., Bertram P. Brown, M.D., Charles Edward Smith, M.D., Karl F. Meyer, Ph.D., W. Ford Higby, Lawrence Arnstein and W. P. Shepard, M.D., Chairman. The committee has made definite proposals to the University of California and has prepared a tentative budget. Interest has been shown by the authorities at the University of California, and the committee is preparing to sponsor a bill in the 1943 California Legislature to provide a special appropriation for the purpose.

Dr. Brown is Past-President of the A.P.H.A. and a long-time member of the Executive Board. He was former Health Officer of Marion County, Ore., and of Mansfield, Ohio. His leadership in the western states has done much to advance understanding between the professions of education and medicine.

OCCUPATIONAL DISEASE REPORTS

The U. S. Public Health Service plans to secure state reports on occupational diseases to be published in *Public Health Reports*, according to the Division of Industrial Hygiene, National Institute of Health.

INSTITUTES ON PROTECTION OF WAR WORKERS

The California Medical Association Committees on Postgraduate Activities and on Industrial Practice, the Western Association of Industrial Physicians and Surgeons, and the California State Department of Public Health arranged a series of one day institutes on health protection of war workers held August 18–28 in 7 strategic centers in the state. The institutes were planned to interest physicians, nurses, safety engineers, and plant managers called upon to supervise health and give medical care to workers in war industries.

INDUSTRIAL HYGIENE FOUNDATION

The Industrial Hygiene Foundation, Pittsburgh, Pa., a research and service institution aiming to protect the health of workers in industry, announces the 7th annual meeting of the Foundation at the Mellon Institute in Pittsburgh November 10 and 11. The program will be focused on reducing the loss of man power through the 2½ million days which war workers are losing weekly from illness and non-industrial injuries. This has a direct bearing on the current war production schedule which calls for a plane every 8 minutes and a tank every 12 minutes.

THE CHARLES V. CHAPIN ANNUAL ORATION

According to the *Journal of the A.M.A.*, the Rhode Island Medical Society has established the annual Charles Value Chapin Oration in honor of the late Dr. Chapin who, throughout his entire career, was active in the field of public health in Rhode Island and Massachusetts. Dr. Timothy Leary, Professor of Pathology Emeritus of Tufts College Medical School, Boston, recently gave the first lecture. Dr. Chapin, who died in 1941, was Superintendent of Health in Providence from 1884 to 1932 and lecturer at the Harvard School of Public Health for many years. He was President of the American Public Health Association in 1927.

THE ERADICATION OF BRUCELLOSIS

The U. S. Department of Agriculture announced on July 6 that North Carolina is the first state to be officially designated as a modified accredited Bang's disease free area. According to the announcement, North Carolina was also the first state of which all counties were declared free of bovine tuberculosis in 1928.

The modified accredited area now includes a total of 550 counties in 24 states. The eradication work is being

conducted in about 160 additional counties. A county may be officially designated as a modified accredited area when a test for Bang's disease has been applied to all cattle 6 months of age or older, except steers, and the percentage of reactors to the last test does not exceed one per cent of the cattle and the infected herds do not exceed five per cent of the total number.

THE LESLIE DANA MEDAL AWARDED TO
LEWIS H. CARRIS

The St. Louis, Missouri, Society for the Blind, in coöperation with the National Society for the Prevention of Blindness and the Association for Research in Ophthalmology, arranged a dinner on October 10 in St. Louis in honor of Lewis H. Carris, Director Emeritus of the National Society for the Prevention of Blindness, New York, on the occasion of the award to Mr. Carris of the Leslie Dana Medal for the Prevention of Blindness.

NURSING IN INDUSTRY

The University of California held a course for nurses in industry July 20 to August 8, conducted by Olive M. Whitlock, R.N., Associate Public Health Nursing Consultant, U. S. Public Health Service. The course was supplemented by demonstrations by industrial nurses and field observation visits.

KANSAS PUBLIC HEALTH ASSOCIATION
MEETING

The Kansas Public Health Association met September 4, in Emporia, the last of the organization's semi-annual sessions, as it was voted to hold the meetings annually hereafter, in the spring. Newly elected officers include:

President—S. N. Mallison, M.D., El Dorado
Vice-President—R. P. Cherry, Wichita
Secretary—Henry H. Asher, M.D., Topeka
Secretary and Executive Officer—F. C. Beelman, M.D., Topeka

PUBLIC HEALTH SERVICE CREATES TUBERCULOSIS SECTION

The Surgeon General of the Public Health Service has announced the establishment in the States Relations Division of a Tuberculosis Control Section to co-operate with the Division of Industrial Hygiene, National Institute of Health, Bethesda, Md. Included in the responsibilities of the new section are the examination of U. S. Coast Guard recruits, workers in war industries, persons in war industry communities, and, in co-operation with Selective Service, the Navy and state health departments, to elaborate a system of reporting cases of young men rejected for tuberculosis. A consultation service is available to state health departments in the development of control programs and units for miniature x-rays are being lent to the bureaus of industrial hygiene and tuberculosis control in case finding.

NEW YORK CITY OFFERS REFRESHER COURSES IN VENEREAL DISEASES

The New York City Department of Health has announced a series of clinical and refresher courses on syphilis and other venereal diseases which opened on September 23. The department has announced that the purpose of this program is to keep physicians in practice abreast of approved diagnostic methods in syphilis, gonorrhea and other venereal diseases.

"PUBLIC HEALTH; RETROSPECT AND PROSPECT"

The New York Academy of Medicine has announced the fall and winter series of a section on historical and cultural medicine to begin on November 4. This meeting will be sponsored jointly by the historical section and by the Committee on Public Health Relations. The first session will include the story of the public and voluntary health agencies in a review of public health in New York City.

KENTUCKY CHANGES HEALTH PERSONNEL

Announcement is made of the appointment of Jacob Leland Tanner, M.D., of Henderson as Health Officer of Washington County.

Paul D. Moore, M.D., Albany, now transferred to Casey County, has been succeeded by William R. Kelsay, M.D., of Monticello as Health Officer for Clinton and Cumberland Counties and Wayne County. Dr. Moore succeeds James T. Duncan, M.D., formerly of Columbia, who has gone to Charleston, W. Va.

Donald B. Thurber, M.D., of Carlisle has been appointed Director of the Tri-County Health District, consisting of Trimble, Carroll and Gallatin Counties.

KANSAS CREATES DIVISION OF INDUSTRIAL HYGIENE

The Kansas State Board of Health recently announced the creation of a division of industrial hygiene to provide consultant service for industries of the state. This will supersede the Industrial Hygiene Service which for the last five years has been a part of the sanitary engineering division of the State Board of Health. Quarters will be provided for the new unit in Topeka, and will be under the direction of Robert M. Heilman, M.D., of the staff of the U. S. Public Health Service.

GRADUATE COURSE IN INDUSTRIAL HEALTH

The Department of Preventive Medicine and Community Health of Long Island College of Medicine at Brooklyn, N. Y., has announced a graduate course in industrial health consisting of lectures and clinics from November 2 to November 13, and industrial internships, November 16 to December 12.

A systematic review of the field of industrial health will be presented by visiting lecturers and the staff of the College of Medicine. Additional in-

formation and a prospectus may be obtained from the College of Medicine, 350 Henry St., Brooklyn, N. Y.

PERSONALS

Central States

FRANK A. BEARDSLEY, M.D., of Frankfort, Ind., has been appointed Health Officer of Clinton County to succeed BRUCE A. WORK, of Frankfort, who is in the Army.

FLOYD L. BURRIS, M.D., is the new Health Officer of Michigan City, Ind., succeeding NORMAN R. CARLSON, M.D., who is with the U. S. Army Air Corps at Hill Field, Ogden, Utah.

ROY H. ELLIOTT, M.D., of Cornersville, Ind., has been appointed Health Officer of Fayette County, to succeed the late JOHN S. LEFFEL, M.D., of Cornersville.

SARKIS H. KASH, M.D., was named Health Commissioner of the Cudahy, Wis., Board of Health at the April 27th meeting of the Board.

ARTHUR LEITER, M.D., of Columbia City, Ind., has been named Health Officer of Whitley County, to succeed OTTO F. C. LEHMBERG, M.D., of Columbia City, who is now a Captain in the U. S. Army.

HOWARD B. METTEL, M.D.,* of the Indiana State Health Department, where he served as Director of the Maternal and Child Health Program and as Director of the Crippled Children's Program of Indiana, has been appointed as Director of Medical and Health Service of the Midwestern Area, American Red Cross, with headquarters in St. Louis, Mo.

HERMAN G. MORGAN, M.D., on August 12 marked the completion of thirty years as administrative head of the Indianapolis Board of Health. He was guest of honor at a dinner on this occasion.

RUSSELL PERRY REYNOLDS, M.D., has

been appointed Secretary of the Garrett Board of Health, succeeding ROBERT A. NASON, M.D., who has entered government service.

JEANNETTE ROSENSTOCK, R.N.,† has resigned as Nursing Supervisor for Health District No. 51, Utah State Department of Health, Richfield, Utah, to assume the position of Nursing Supervisor for the newly unified Topeka City-Shawnee County Health Services with headquarters at Topeka, Kans.

CECIL A. Z. SHARP, M.D.,† State District Health Officer, Highland, Ill., has been placed in charge of a new health unit in Will County.

HARRY WAIN, M.D., M.S.P.H.,† of Sidney, Ohio, has resigned as Health Commissioner of Shelby County and Sidney, to become Health Commissioner of Troy and Miami County, Ohio.

Eastern States

THOMAS D. DUBLIN, M.D., DR.P.H.,† has resigned as Epidemiologist in the Division of Communicable Diseases, New York State Department of Health, Albany, to accept an appointment as head of the Department of Preventive Medicine and Community Health at the Long Island College of Medicine, Brooklyn, N. Y. Dr. Dublin was graduated in medicine from Harvard and in public health from Johns Hopkins School of Hygiene. He has served on the medical staff of the Hospital of Rockefeller Institute for Medical Research, and has been instructor in preventive medicine at both the Johns Hopkins University Medical School and the Albany Medical College. Dr. Dublin is a son of LOUIS I. DUBLIN, PH.D.,* Vice-President of the Metropolitan Life Insurance Company, New York, N. Y., and Treasurer of the American Public Health Association.

* Fellow A.P.H.A.

† Member A.P.H.A.

CARL R. FELLERS, PH.D.,* Research Professor of Horticultural Manufactures at the Massachusetts State College, Amherst, has been called to active duty with the Army in the Chemical Warfare Section.

FRANKLIN M. FOOTE, M.D., DR.P.H.,* who for 2 years has been District Health Officer in the Kips Bay-Yorkville area of New York City, in co-operation with the Cornell University Medical College, has been called to active duty as a Captain in the Medical Corps of the Army and is stationed at Pine Camp, N. Y.

JOHN E. GORDON, M.D., PH.D.,* Professor of Preventive Medicine at the Harvard Medical School, Boston, Mass., who for some years has been serving in charge of the Harvard-Red Cross Hospital in England, has been appointed Lieutenant Colonel, U. S. Army Medical Corps and has been assigned to the Division of Preventive Medicine, Office of Chief Surgeon, Headquarters SOS, European Theatre of Operations.

IRA V. HISCOCK, C.P.H., Sc.D.,* Professor of Public Health, Yale University School of Medicine, Department of Public Health, New Haven, Conn., Lt.-Col., Reserves, U.S.A. Sanitary Corps, was called to active military service and left New Haven, Conn., September 23, 1942.

ERNEST B. HOWARD, M.D., M.P.H.,† formerly of the Division of Genitoinfectious Diseases in the Massachusetts Department of Health, Boston, is now Captain in the Army Medical Corps on Duty as Venereal Disease Control Officer assigned to the Fourth Service Command, Atlanta, Ga.

HARRY E. KLEINSCHMIDT, M.D.,* New York, N. Y., has resigned as Director of Health Education for the National Tuberculosis Association and has been appointed Director of Medical

and Health Service for the American Red Cross North Atlantic Area, with headquarters in New York, N. Y.

CLIFFORD KUH, M.D., DR.P.H.,† of New Haven, Conn., who has been Chairman of Industrial Health for the Connecticut State Medical Society, has resigned and has been appointed Director of the Bureau of Industrial Health of the California State Department of Health, San Francisco.

DAVID R. LYMAN, M.D., Superintendent of Gaylord Farm Sanatorium, Wallingford, Conn., received the degree of Doctor of Science recently from Wesleyan University, Middletown, Conn.

LEE B. MAILLER, Assemblyman, of Cornwall, N. Y., Chairman of the New York State War Council's health preparedness commission, has been appointed a special consultant in the U. S. Public Health Service.

STANLEY H. OSBORN, M.D., C.P.H.,* Connecticut State Commissioner of Health, Hartford, received the degree of Doctor of Science at the 86th commencement of Tufts College recently in Boston.

ROBERT W. RIPLEY, M.D., of New York, has been appointed Assistant District Health Officer for Benton and Franklin Counties and the western portion of Walla Walla County, Washington, with headquarters in Pasco.

BENJAMIN SACHS, M.D., M.S.P.H.,† of New York, N. Y., has been appointed Director of the Acadia Parish Health Unit, Louisiana State Department of Health, with headquarters at Crowley, La.

LEON SCHWARTZ, M.D.,† P. A. Surgeon (R), U. S. Public Health Service, recently of Philadelphia, Pa., has been called to active duty and has been placed in charge of the health program for the U. S. Bureau of the Census in its new building at Suitland, Md.

* Fellow A.P.H.A.

† Member A.P.H.A.

Southern States

HAROLD B. GOTAAS,† formerly Professor of Sanitary Engineering in the School of Public Health, at the University of North Carolina, Chapel Hill, has been commissioned Captain in the Sanitary Corps and is serving as Chief of the Engineering Section of the Division of Health and Sanitation in the Office of the Coördinator of Inter-American Affairs, Washington, D. C.

HENRY HANSON, M.D.,* has been appointed State Health Officer of Florida, effective July 15, succeeding WILLIAM H. PICKETT, M.D.,* of Jacksonville, who has been commissioned in the U. S. Public Health Service. Dr. Hanson formerly served as Health Officer of Florida and recently has been working in South America, chiefly in Ecuador and Peru as technical adviser in bubonic plague eradication and in jungle fever and malaria control.

CLAIR A. HENDERSON, M.D., of Savannah, Ga., has resigned as Assistant City-County Health Officer of Savannah and Chatham County, to become Commissioner of Health of Augusta and Richmond County, effective July 1. He succeeds THOMAS B. PHINIZY, M.D.,† of Augusta, who recently resigned.

JOSEPH HIRSH,† Washington, D. C., has been called to active duty as First Lieutenant in the Sanitary Corps, U. S. Army, and assigned to the Army Technical School at Sioux Falls, S. D., where he is Assistant Medical Inspector, Sanitary Officer and Venereal Disease Control Officer.

SALLY LUCAS JEAN,* formerly Secretary of the World Federation of Education Associations and a consultant in health education, has been appointed Health Education Super-

visor with the Colorado River Relocation Project with headquarters in Poston, Ariz.

ANNETTE KING, who has been associated with the West Virginia State Department of Health at Charleston for the past 17 years, has been appointed Acting Director of the Bureau of Public Health Education and Public Relations, succeeding DOROTHEA CAMPBELL,† who died September 20 after fifteen years of service as Director of the Bureau.

PAUL P. MCCAIN, M.D.,† Superintendent of the North Carolina Sanatorium for the Treatment of Tuberculosis, Sanatorium, S. C., and the Western North Carolina Sanatorium, Black Mountain, S. C., has been named to a similar position at the Eastern North Carolina Sanatorium now under construction in Wilson.

FRANK L. MCGAHEY, M.D., formerly of Calhoun City, Miss., has been appointed chief of the Grenada County Health Department.

ALLAN J. McLAUGHLIN, M.D.,* medical director retired, U. S. Public Health Service, Washington, D. C., has recently served in Illinois as consultant to the Committee on Administrative Practice of the A.P.H.A. in connection with the state-wide survey. Dr. McLaughlin's appointment has been announced as medical administrative consultant to the Illinois State Department of Health.

NELS A. NELSON, M.D.,* of Baltimore, Md., Director of the Division of Genitoinfectious Diseases of the Massachusetts Department of Health. Boston, Mass., since 1938. has been appointed Deputy State Health Officer of Maryland. Dr. Nelson formerly served in the Division of Communicable Diseases of the Massachusetts Department of Health. He is an associate in venereal diseases at the Johns Hopkins University School of Hygiene and Public Health, and

* Fellow A.P.H.A.
† Member A.P.H.A.

consultant to the U. S. Public Health Service.

GEORGE E. PARKHURST, M.D., of Charleston, S. C., Assistant Surgeon, U. S. Public Health Service, has been assigned as Director of the Venereal Disease Program of the Charleston County Health Department.

P. M. PAYNE, M.D.,† formerly director of the Assumption Parish Health Unit, Napoleonville, La., has been transferred to the Evangeline Parish Health Unit at Ville Platte, La., as Director.

WILLIAM H. PICKETT, M.D.,* formerly State Health Officer in Jacksonville, Fla., has been commissioned in the Reserve of the U. S. Public Health Service and has been assigned to duty as Director of Health for Kansas City, Kans., effective August 1.

GEORGE E. RILEY, M.D., Health Officer of Clay County, West Point, Miss., has been appointed Director of Hinds County Health Department, Jackson.

CURTIS M. ROBERTS, M.D., of New Albany, Miss., has resigned as Health Officer in Prentiss County, to accept a similar position in Clay County, with headquarters in West Point.

Western States

J. J. BLOOMFIELD* recently gave five lectures in connection with the University of California's Industrial Training Series, using as his topics Industrial Hygiene Problems in the United States; Effect of the War; National, State, and Local Industrial Hygiene Services; and Health Education.

FRED T. FOARD, M.D.,* Surgeon, U. S. Public Health Service, San Francisco, Calif., has been assigned as Regional Medical Officer for the Ninth Civilian Defense Region, with headquarters in San Francisco.

ABRAHAM L. GELPERIN, M.D.,† of Baltimore, Md., has been appointed Venereal Disease Control Officer of Richmond, Va., succeeding AARON WILSON BROWN, M.D., of Pocatonton, who recently resigned to enter private practice.

ELBERT GOOLSBY, M.D., was recently appointed Health Officer of Paris, Tex.

WILLIAM GROSSMAN, M.D.,* of Richmond, Va., has accepted a commission in the U. S. Army, resigning his position as Director of the Bureau of Communicable Diseases in the Virginia State Health Department.

IRVING D. JOHNSON, M.D., C.P.H.,† of Marysville, Calif., has resigned as Health Officer of the Sutter-Yuba Bi-County Public Health Unit in order to organize a new department in Marin County, at San Rafael.

EUGENE L. KIDD, M.D.,† of Centralia, Wash., formerly Health Officer of Lewis County, has been placed in charge of the unit in Snohomish County with headquarters in Everett.

DR. RAYMOND DE VAN KIMBROUGH, of Norfolk, Va., was appointed on June 1 as State Venereal Disease Control Officer for the Tidewater Area, Va.

ROSCOE C. MAIN, M.D.,* of Santa Barbara, Calif., has resigned as Health Officer of Santa Barbara County, after 13 years of service, to become senior physician in the communicable disease section of the Los Angeles County Health Department.

GRUNDY E. McDONALD, M.D.,* resigned as Health Officer of Long Beach, Calif., on August 15, and has been succeeded by his assistant, FRANK W. STEWART, M.D.†

F. A. MUSACCHIO, M.D., M.P.H.,† formerly Director of the Acadia Parish Health Unit, Crowley, La., was recently appointed Director of the St. Mary Parish Health Center,

* Fellow A.P.H.A.

† Member A.P.H.A.

Franklin, La., to succeed Dr. G. VASQUEZ, who is on military leave.

JAMES A. OUTLAND, M.D., of Murray, Ky., Health Officer of Calloway, will take over the work in Trigg County.

This is a result of the resignation of LEONARD A. CROSBY, M.D., of Eddyville, Ky., who has been in charge of Caldwell, Lyon, and Trigg Counties.

W. W. PETER, M.D., Dr.P.H.,* formerly Medical Director, Navajo Area, U. S. Indian Service, Window Rock, Ariz., has accepted a war service appointment as Associate Professor of Public Health in the Department of Public Health, Yale University School of Medicine, New Haven, Conn.

FRED W. SUTTON, M.D., has been placed in charge of the Health Department of Beaumont, Tex., succeeding CHARLES HUGH TODD, JR., of Beaumont, resigned.

PAUL L. WERMER, M.D.,† formerly Director of the Upshur County Health Unit, has been transferred to take

charge as Director of the Waco-McLennan County Health Unit, Waco, Tex.

Foreign

EDUARDO ESCUDERO, M.D., of Santiago, Chile, has been appointed as Minister of Public Health and Social Welfare of Chile, it has been announced.

PABLO MORALES OTERO, M.D.,† has been appointed Director of the School of Tropical Medicine, University of Puerto Rico, San Juan, by Columbia University, with which the School of Tropical Medicine is affiliated. Dr. Morales has been Acting Director of the School for some months. He succeeds GEORGE BACHMAN, Ph.D., who is now in China representing the American Board for Medical Aid to China in Chungking.

DR. CAESAR GORDILLO ZULETA, of Lima, Peru, has been appointed as General Director of Public Health, it has been announced.

Public Health and Civil Defense in Great Britain During the War*

W. M. FRAZER, O.B.E., M.D., M.Sc.

*Medical Officer of Health, City and Port of Liverpool; Professor of Hygiene,
University of Liverpool, Liverpool, England*

THE point of view which I shall express in this communication is that of the medical officer of health of a large English city and port through which many of your nationals have passed when visiting Great Britain and Europe in peace time, and through which Americans are still passing for other and grimmer purposes. It was laid down by the Ministry of Health and the Ministry of Home Security early in 1939 when our air raid precautions schemes were commencing to take shape, that the medical officer of health should be responsible for such civil defense services as emergency ambulances, first aid posts, first aid parties (stretcher bearers), mortuaries, and the emergency extensions of the local authority's hospitals. He is, in fact, in charge of the casualty services, being responsible for the care of the injured, and the disposal of the dead, and, in addition, is associated with a number of other services

which have been established to deal with various difficulties arising both from the effects of air raids and from the upset to the life of our crowded urban populations due to movements of the population in furtherance of the war effort. Thus, medical arrangements are required in connection with the larger public shelters, with rest centers, evacuation schemes for school children, expectant mothers and blind persons, and to supervise day and residential nurseries for the children of mothers engaged in the war factories which have been established in all industrial parts of the country. All these arrangements for dealing both with actual casualties from air raids and with the multifarious difficulties of the civilian population under war conditions were made under general instructions issued by the Ministry of Health and Ministry of Home Security and followed a pattern which was therefore common to the whole of Great Britain, such slight differences as existed being due to local circumstances. Our arrangements in Liverpool in air raids were accordingly similar to those

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

of other urban areas which were heavily bombed during the period from August, 1940, to May, 1941; and my observations on the subject in this paper, although arising from experience in Liverpool, apply to a considerable extent to other parts of the country.

Let us consider the situation as it was in any urban area in Great Britain likely to be subjected to heavy bombing, in early August, 1940, just before the onset of air raiding. Take first of all that indefinable quality of the communal spirit termed morale. That it was high was not, I think, due to ignorance of the terrible effects of heavy bombing, because morale remained satisfactory even after months of attack had caused severe damage to many industrial areas and had taken heavy toll of human life. The courage of our population in such circumstances had its origin in a complex of factors among which are clearly discernible a profound conviction of the justice of the cause in which we were engaged and a feeling of confidence in the government, and especially in the Prime Minister, Mr. Churchill, whose speeches at that time, sometimes given over the wireless, were a source of great inspiration to the average man and woman called upon to face the imminent horrors of air bombardment. But we had other sources of consolation—the support of the Dominions, the friendship and material help of the United States, and the feeling of comradeship which rapidly strengthened between all classes in the community called upon to face together a common peril. At that time—early in August, 1940, before air raids had commenced in earnest—our civil defense services were in an advanced state of preparation but were by no means complete, and large numbers of people were voluntarily serving as wardens, ambulance drivers, stretcher bearers, fire-watchers, telephonists, and the like. The fact that unlimited opportunities

for service were available was a fortunate circumstance and it had a profoundly favorable influence upon civilian morale. I hope I may be allowed to speak from personal experience when I say that there is nothing which sustains one's courage and fortitude during an air raid so much as doing a job and forgetting about the air raid.

Another favorable circumstance was the fact that we in Great Britain had been led to expect that air raids were going to be made in overwhelming force at the outset of the war, and provision was actually made for dealing with many thousands of casualties in the large centers of population. You may judge of our surprise in Liverpool, for example, when the first raids happened and we found that casualties were counted, not in thousands or hundreds, but only in scores. It almost looked as if the size of the Luftwaffe was a product of the German propaganda machine rather than of their factories. But that comparatively happy situation did not continue after the first few months, and later we experienced very severe raiding with large casualty lists; and when that began to happen our civil defense personnel had been thoroughly trained in the hard school of war, shelters had been rapidly increased in number, and the arrangements for caring for the many homeless people after a night's air raid had reached a satisfactory degree of efficiency.

Another circumstance favorably affecting the health and morale of the community was the excellence of the food supply. Prior to the outbreak of war the Government had set up a branch of the Board of Trade under Sir Henry French to consider the question of the nation's food in the event of war, and to work out the complicated and detailed administrative arrangements for the early rationing of certain of the principal foodstuffs such as meat, fats,

and sugar in the event of hostilities occurring. This branch was expanded and took shape as the Ministry of Food in 1939 on the outbreak of war, and almost immediately rationing of meat, sugar, fats, and tea was introduced. At first rationing was limited to these articles of food, and the scale was a generous one, but as time went on other foodstuffs were rationed, and today all important foodstuffs are dealt with under the rationing system except bread, potatoes, and vegetables, of which unlimited amounts can be obtained. In spite of moderately severe rationing it can be said with confidence that the population of Great Britain is today in all respects adequately nourished, and this expression of opinion applies to children as well as to adults. Children are, in fact, well looked after from the dietetic point of view, having a larger milk ration than the adult, while babies under the age of 3 years receive fruit juice concentrates, such as black-current puree and rose-hip juice, as well as the additional milk ration. Vitamin C deficiency has only exceptionally occurred among the infant population of Great Britain during this war, although in 1914-1918 it was relatively common.

The activities of the Ministry of Food are not, however, restricted to the importation of food and the imposition on the population of a rationing system. This department, under the leadership of Lord Woolton and guided by the advice of Professor Drummond and Lord Horder, has shown great wisdom in arranging for cheap and nutritive meals to be available for all workers at canteens for which food is provided apart from the ration. Mobile canteens, some of which have been sent through the generosity of voluntary societies in the United States, supply food to workers in isolated places and to civil defense personnel during long air raids. A system of National Kitchens has also been developed under the auspices of

local authorities, where meals can be obtained by any persons requiring them, again without the surrender of ration coupons. The principle underlying these arrangements is that the supply of food cooked in large quantities at communal kitchens is an economy because both fuel and time are saved and variety is more readily obtained, while some of the hardships imposed on very small families by the rationing system are mitigated. Another provision made by the Ministry of Food, which has had favorable results from the public health point of view, has been the introduction of a national wheat flour of 85 per cent extraction to replace the white flour previously almost universally in use in Great Britain. This flour, from which appetizing bread and moderately satisfactory cakes are made, contains nearly three times as much of the main items of the vitamin B complex, nearly three times the amount of iron and more than twice the weight of mineral salts as are contained in white (73 per cent extraction) flour.

Looking back on the Ministry of Food's policy during the last three years, the judgment may be fairly expressed that the population of Great Britain has been kept in a state of adequate nutrition, and health and working capacity have been well maintained, even if luxuries have, perforce, had to be abandoned. There has been a levelling of food consumption since, except for the black market which has never attained large dimensions, both rich and poor enjoy practically the same diet. It is true, of course, that the rich are poorer because of heavy taxation and the poor richer because unemployment has disappeared and wages are relatively high; and the final result of this economic change, under the rationing system, is that every class in the population is being fairly treated from the rationing point of view, so that there is widespread satisfaction with the

way the Ministry of Food has performed its task.

Especially noteworthy has been the coöperation existing between the Ministry of Food charged with the duty of distribution, and the Ministry of Agriculture whose duty it is to encourage the production of food. Under the guidance of the latter Ministry, farmers have brought under cultivation many millions of additional acres of land, milk production has increased, and the people, both in the towns and in the country, are using all the available space in their gardens in order to grow potatoes and vegetables. Great Britain during the past two or three years has become a nation of gardeners. All are helping, all are interested, and there is keen competition between neighbors to produce the finest peas, potatoes, lettuce, and tomatoes. The net result of all these activities is that Great Britain, for the first time in her recent history, is producing at home about two-thirds of the food she consumes; much shipping space is thereby saved and an adequate supply of the protective foods is insured, to the great advantage of the health of the community.

In order to keep in touch with the situation in regard to nutrition in the country, the Ministry of Health has initiated surveys which are being assisted by two expert medical officers supplied by the International Health Division of the Rockefeller Foundation.

The next factor influencing the public health in Great Britain during the present war is that of movements of population proceeding in ever increasing measure during the past three years. These movements, defensive in character as regards the evacuation of children from crowded urban districts to small towns and rural areas, but offensive and directly related to the war effort in the call-up of man power and woman power to the services and to factories, have now assumed large pro-

portions; and have, of course, created many sociological, ethical, and epidemiological problems. It is with the latter that we are mainly concerned. That population has altered to a considerable extent is shown by the experience of one large urban area—perhaps not an entirely typical one—where today the number of civilians is only two-thirds of the corresponding figure three years ago. Apart from the regular services—the Army, Navy, and Air Force for men and the A.T.S., W.A.A.F. and W.R.N.S. for women—such activities as factory work, labor at the docks, the National Fire Service, the Women's Voluntary Service, and the Civil Defence Service have all caused internal movements of the population and, except in the case of the armed forces, the trend has on the whole been toward, rather than away from, the larger cities.

The epidemiologist, bearing in mind the historic consequences of movements of population under adverse sanitary conditions and in a different age, tended, before 1939, to view the population changes, inevitable in wartime, with some apprehension. And, indeed, in one or two respects, his pessimism has been justified as far as Great Britain is concerned since experience has shown that three diseases, two major and the other minor, have largely increased as a result of the war, although, speaking generally, the epidemiological situation has been satisfactory.

One of the major conditions referred to is venereal disease which is spreading with some rapidity in Great Britain, especially, of course, in the port areas and industrial towns. In Liverpool the incidence of cases of syphilis attending for treatment at the venereal diseases clinic is about four times what it was before the war, and twice in the case of gonorrhea. Other large ports return a similar increase. In spite of the widespread provision of treatment facili-

ties in all areas, venereal diseases are taking a severe toll in terms of human health and happiness, marital infection being an almost unavoidable consequence. This evil of the spread of venereal disease during the war is well known throughout the country and is being urgently discussed in official circles and in various voluntary societies which are interested in the social condition of the people; but, as we are all aware, the problem of prevention of a disease arising from sexual relations presents features which go far beyond the domain of public health and epidemiology. Because questions of ethics, religion, and law are involved, the subject of the prevention of venereal diseases has seldom, at least in Great Britain, been examined in the impartial and scientific way in which the hygienist would discuss, for example, the subject of immunization against diphtheria, and as a consequence while progress in treatment has been outstanding, progress in regard to prevention, even on the propaganda side, has been very slight.

It is recognized, of course, that, next to the avoidance of risk altogether, early treatment, by rendering the patient non-infectious within a period of days in the case of gonorrhea and weeks in the case of syphilis, is the best method of prevention available. But in Great Britain, at least at present, the attempt at solving this serious public health problem ceases with the provision of full treatment facilities for both sexes, and other methods, although now being considered, have not been tried. One body of medical opinion thinks that notification together with compulsory treatment of one or both sexes is well worth a trial, but it is recognized that the administration of such a system presents formidable legal difficulties, and the adoption of compulsion in regard to treatment would constitute a great departure from our national tradition. Nevertheless, other

countries such as Sweden possess compulsory powers and it is not inconceivable that Great Britain, under the stress of war, may be driven to take some action in the same direction. Certainly the present situation is not a very satisfactory one for the health officer.

On a few occasions I have received, through the English Ministry of Health, letters from American cities complaining that one of their nationals has returned home after infection from a named woman in Liverpool and asking that some action should be taken. From this I assumed that there are powers for compulsory treatment in some of your states and I know now that that is the case. But in Great Britain a medical officer of health is quite powerless to take compulsory action of any kind and he is always in danger of an action for libel or slander—concerning which the law in England is much more inconvenient than it is in your country where, I understand, freedom of speech really means what it says.

The minor disease, the spread of which is ascribable to movements of the population, is scabies. Prior to the war scabies was of slight consequence, very few cases being reported even among school children; but during the past two years the number of cases of this trivial and easily cured skin condition has increased to an enormous extent. The researches of Kenneth Mellanby show that scabies spreads from one person to another as a result of fairly close contact, and he is of opinion that the commonly accepted view of frequent infection through the medium of blankets is erroneous. In Liverpool we have opened about eighteen treatment centers for dealing with this condition and many thousands of cases are being dealt with. Nevertheless, scabies is now, in spite of our efforts, widespread throughout the community and it seems unlikely that it will be stamped out until after the war.

The other salient features of the epidemic situation since the outbreak of hostilities are the occurrence of a small number of outbreaks of paratyphoid B, not, it is thought, due to the war; and the second major disease a significant increase in the pulmonary tuberculosis notification rate in respect of age groups from 15-25 and 25-35 in the case of females, and 45-55, 35-45 and 25-35 in the case of males. In the opinion of those who have analyzed the figure of occupational mortality and morbidity, these increases in the incidence of pulmonary tuberculosis are due, not to food deprivation, but to overwork and overstrain directly occasioned by the war effort.

Regarding other major infectious diseases there is happily little to be said. Before the war there was no indigenous typhus, malaria, or smallpox in Great Britain so that, for outbreaks of these diseases to occur, importation of the infecting agent would have to take place. It is, of course, well known that typhus is now widely spread throughout Europe, not only in the East and South East where it has for years been endemic, but also in the West. Precautions have accordingly been taken at the British ports and a vigilant scrutiny of persons entering the country who have come from countries infected with typhus is being undertaken. On one or two occasions a case of smallpox has been admitted into the country and there has been one small outbreak of this disease, arising not from the original case but from a contact. There is so far no malaria imported from outside.

We are, therefore, fortunate in having escaped in three years of war any epidemics of the major infectious diseases and we are hoping, perhaps with some justification for our precautions have been carefully taken, to prevent the importation of typhus, malaria, and smallpox from the neighboring and unhappy continent of Europe. If we suc-

ceed in this effort it will be partly due to forethought and perhaps a little to luck, which no epidemiologist can afford to despise.

The direct danger of epidemics resulting from air raids was thought before the war to be likely only in connection with fractured water mains which might become heavily contaminated with sewage and thus cause an outbreak of typhoid. It may be said at once that this danger, although apprehended on apparently adequate grounds, has never materialized, and it has been reported by the Minister of Health recently that not one typhoid death in Great Britain during the period of heavy bombing has been due to pollution by water-borne infection. As far as Liverpool is concerned, it is certain that no case of typhoid occurred which could be traced to infection of the water supplies as a result of fractured mains. There are probably two factors which have led to this remarkable freedom from typhoid fever in spite of continuous bombing of crowded areas—a feature of our health record which has amazed American medical visitors to Great Britain. The first of these factors is the scarcity of typhoid fever in the urban areas in most years, although an epidemic of perhaps a few hundred cases may infrequently occur. In an average year the City of Liverpool, for example, will show a return of less than a dozen sporadic cases of typhoid and many years have elapsed since an epidemic of this disease last occurred. Most of the larger cities can tell a similar tale and, as a consequence, typhoid carriers are very scarce in the areas most subjected to bombing, and sewage which may have contaminated some of the water mains is unlikely to be infected. In the second place, arrangements are available in all large areas for heavily chlorinating the water in repaired mains before putting them into service again and, although this

system was not used universally during the heavy bombing raids, it was sufficiently employed to serve as a valuable safeguard. As far as London was concerned, the Metropolitan Water Board has, from the start, used mobile chlorinators with liquid chlorine for the larger mains (*i.e.*, more than 12 ins. in diameter), and bleach for the smaller mains; the amount of the chemical being calculated to give 10 parts per million in the repaired main. Because of the experience in Great Britain that the risks of outbreaks of typhoid are slight, immunization against this disease has not as a rule been regarded as necessary, but vaccines are available and would be used for mass inoculations if this was thought desirable.

I have been discussing conditions affecting generally the state of the public health in Great Britain during the three years commencing September, 1939, when war with Germany was declared. I propose now to consider in rather more detail the purely civil defense side of my subject with a view to discussing what effects the elaborate arrangements made to safeguard our population against the dangers of air raids had in protecting life and limb, health and morale during the period from August, 1940, *i.e.*, when raiding began, to May, 1941, when, as if by a miracle, this form of attack suddenly ceased. It may be that for the sake of clarity it will be necessary to repeat occasional items of information given in the preceding pages and if this happens my excuse—with infinitely less cause—must be that of Lord Bryce, at one time our British Ambassador to your country, who in his monumental work on the American Commonwealth expressed the opinion that if an author is obliged to choose between repetition and obscurity there should be no doubt as to the nature of his choice.

In order to be in a position to consider the subject from a practical point

of view, let us discuss in detail what actually happens during a severe air raid on a British city. Suppose that the raid is of such dimensions that it entails a casualty list of 1,000 killed and 2,000 severely or slightly injured. A raid of this kind may be regarded as severe relative to the scale of raiding between August, 1940, and May, 1941, although not comparable to what has already happened on many occasions to German towns during the present year.

On the air raid alarm being sounded, all staff on stand-by duty either at their homes or at depots report and make ready for eventualities. Less than half-an-hour after the alarm all control centers and ambulances, first aid party and rescue party depots should be fully manned. The chief officers of the main services, *e.g.*, casualty services, rescue services, fire and water services, police, etc., with the control officers, are on duty at the city's main report and control center, while the divisional report and control centers and depots, on which the first impact of the raid will fall, are making the final preparations for immediate action.

Then sometimes there is a wait of several minutes before the first report of an "incident" will be received at a divisional control center from a warden by telephone. The air raid has begun. I have used the term "incident" and this requires explanation. An incident—surely a masterpiece of understatement—is any occurrence during an air raid which leads or may lead to injury to persons or damage to property, such as the explosion of a heavy bomb on a block of buildings, the fall of an incendiary bomb on a house, the dropping of a time bomb in a field near some buildings, destruction by blast of windows or doors, and even the fall of an unexploded anti-aircraft shell or shell splinters, if injury or damage is occasioned.

All these events—large or small—are

incidents and are reported to divisional control by the wardens as soon as possible. Wardens have a special report form and have been trained to report by telephone according to the headings on the form. Thus an attempt is made to give a complete picture of the incident—the approximate number of casualties, an idea of the damage resulting, whether a road has been blocked, or water or gas mains opened up, electric cables, telephone or tramway wires broken, etc. This telephoned report is entered on a form at divisional headquarters and it forms the basis for any immediate action taken, further reports on the same incident being telephoned from time to time as events develop. A usual event requiring a supplementary report is the occurrence of a fire which may break out or be discovered after the preliminary report has been dispatched.

In actual experience, under the hazardous conditions obtaining at the scene of an incident, wardens' reports are by no means accurate and this inevitably leads to unsuitable action being taken at the divisional report and control center which may send too many or too few services, or may perhaps fail to send a service which is urgently required. As a remedy for this difficulty the practice has grown up of sending to the location of the incident an "immediate action party" consisting of one ambulance, a car containing a first aid party of two persons, and a small rescue party with its own vehicle. This party is under the charge of an experienced man whose duty it is to assess the dimensions of the incident and report to the divisional control center what further services are required; the parties meanwhile dealing with the most urgent casualties.

If the incident is a large one with much damage and many casualties, such as occur when a large building is destroyed or a public air raid shelter or hospital severely damaged, it is cus-

tomary to establish an "incident post" in a convenient situation near to the scene of the disaster and to place the local control in the hands of an incident officer who is usually a police inspector and to whom the leaders of all services report for general directions. The main duties of the incident officer are to coördinate the various services, to report from time to time to divisional control as to the progress made in dealing with casualties and damage, to give directions for the regulation of traffic at or near to the site of the incident, and to return to their depots as soon as possible redundant services. This last named duty is important, as there is a marked tendency on the part of the divisional control centers and also the main control centers to send to the scene of a serious incident of the kind I am discussing more ambulances, first aid parties, and rescue parties than can usefully be employed at any given time on the site of the disaster. Such action on the part of various chief officers at main headquarters in the face of a disaster to a hospital or a large public air raid shelter is only natural, as reports are often imperfect or misleading and tend to exaggerate the magnitude of the occurrence, but the temptation to play for safety and send an unduly large proportion of ambulances and parties to a major incident should be sternly resisted during a severe air raid, as these services may be urgently required elsewhere.

If I may be permitted a personal confession—I remember at least three occasions when I was guilty of this error of judgment during the raids over Liverpool between August, 1940, and May, 1941. These occasions were in connection with the demolition of a hospital, the firing of a train loaded with ammunition and the destruction of a large public shelter. Each of these incidents caused much loss of life and, in the case of the train, widespread de-

struction; but to me, the saddest occurrence of all during more than 100 air raids was the demolition of a large municipal hospital and the loss of much esteemed medical and nursing staff, including two medical students. On that occasion we sent during the night many ambulances and first aid and rescue parties, some of which were quite properly returned to the depots by the incident officers. The hospital staff rightly took the ambulances and parties as a matter of course; but what was highly appreciated was the dispatch of a mobile canteen on a Chevrolet chassis, one of several presented to the city through the generosity of certain voluntary societies in the United States. Indeed, according to the testimony of several junior members of the nursing staff of the hospital, this mobile canteen saved more lives than the ambulances.

Action at the scene of an incident is not, of course, confined to the night of the actual air raid. Many persons, trapped in debris, but protected in basements or under arches formed by beams and girders, are rescued the following day and a few are found alive two or three days after the raid. A proportion of them die from shock or exposure shortly after extrication from the debris.

Many bodies are recovered days or weeks after the raid and add to the figures of casualties, which cannot, therefore, be accurately compiled until a considerable time has elapsed after the night of the raid. Day after day the rescue parties tunnel under the debris, often in highly dangerous circumstances, until all persons known to be in the building have been accounted for. The compilation of the list of persons buried under the debris is usually the duty of the incident officers, and it is not the least responsible of his duties, since omissions from it may lead to losses in lives through the premature abandonment of the search in the debris, while the inclusion of the names

of persons who were away or safe in shelters wastes the time of the hard pressed rescue parties. It has been a rule in Liverpool that the search in the debris of a demolished building shall not be given up until the incident officer is satisfied that all persons who might be alive have been rescued.

If the raid is a large one, as we are assuming, incidents small and great are occurring in many parts of the area and in adjacent areas, because enemy bombs are no respecters of local government boundaries; and ambulance and first aid and rescue staffs are busily engaged throughout the night in their dangerous but humanitarian occupations. The fire services—taken out by the Central Government from the local authorities months ago—are certain to be heavily engaged, since many and extensive fires are the invariable accompaniment to any air raid. Damage from fires is, in the aggregate, greater than direct damage from bomb explosions and it can only be minimized by highly efficient fire services, the system including elaborate arrangements for fire-watching, in which a large part of the adult population, male and female, is compulsorily engaged. Fires tend to create panic, do extensive damage not of course confined to the original site, and cause not a few casualties. The British experience in 1940 and 1941 was that in large raids the fire services were insufficient in many areas so that some fires had to be neglected until too late, owing either to the lack of personnel and equipment or to the absence of adequate water supplies. We have now a well equipped National Fire Service, elaborate fire-watching arrangements, and emergency supplies of water stored in metal, brick, or concrete tanks in all vulnerable areas.

The Medical Officer of Health's services are not, however, concerned with fires, but only with casualties arising from any cause, and his main duty is to convey injured persons away from the

scene of the incident as expeditiously as possible to hospitals and first aid posts. In Liverpool it is an instruction to first aid party leaders that a minimum of first aid should be given and that it is in the patient's interest that he should receive skilled medical and nursing attention at the earliest possible moment. Elaborate first aid procedures are therefore avoided, little splinting is done, sandbags along the side of an injured limb being often all that is necessary; but tourniquets are, of course, used to check serious arterial hemorrhage.

The amount of first aid required will depend upon the distance the patient has to be carried to hospital. In Liverpool and other large cities distances are short and accordingly little first aid is given; in rural areas, with long distances to the nearest hospital, more first aid would be necessary.

In Great Britain there has been an extensive call-up of doctors for the services and it is seldom that medical practitioners can be spared to deal with casualties except at large incidents. However, we have a small number of mobile surgical units equipped with instruments, drugs, and dressings and when called out these are accompanied by a doctor and two or more nurses. As far as possible mobile units are only sent to incidents where there are many serious casualties and the doctor and nurses, assisted by first aid men, may then undertake some rough surgery, give injections of morphia, and check serious hemorrhage. There have been occasions when the doctor sent out with a mobile unit has amputated a badly injured limb of a person trapped in wreckage, but the conditions calling for such heroic surgery are fortunately seldom present and the results, as might be expected, are generally unhappy.

One extremely useful function performed by the medical man in charge of a mobile unit is the giving of morphia to injured persons suffering from seri-

ous pain. The proportion of such cases is not, surprisingly enough, very large, and shock and hemorrhage remain our greatest problems.

So far I have been discussing action at the site of a bomb explosion or other air raid incident, and I propose now to shift the scene to the city's Central Air Raid Precautions Headquarters, usually referred to as the Main Report and Control Center. Here during an air raid are stationed the heads of the various services, such as the Chief Constable, the City Engineer, and the Medical Officer of Health. Each of these officers is assisted by a small staff and he is represented at all the divisional report and control centers. During the air raid, "situation reports" in connection with every incident are transmitted by the divisional operations centers to main headquarters and thus a fairly clear picture of the course the raid is taking throughout the city is presented. It may become evident that one or two parts of the area are bearing the main brunt of the attack and this will lead the heads of services to reinforce from other divisions the division or divisions subjected to heavy attack. From time to time requests will be received from adjacent local authority areas for the loan of ambulances or parties, and as far as possible applications of this kind are met at once by large cities with abundant services under arrangements for mutual aid which have been made under the general directions of the regional commissioner. Groups of local authorities have been formed in all areas and mutual support is controlled by a special officer—the Group Officer for Mutual Support—through whom applications for reinforcements within the group or from one group to another are received. If reinforcements are required to proceed from one region to another arrangements are made through the regional commissioners. In Liverpool, however, this was seldom required.

in connection with the ambulance, first aid, and rescue party services, but the need for reinforcement from group to group and region to region was often experienced in the case of the fire services and was one of the main reasons for the nationalization of this branch of the organization.

As far as the casualty services were concerned, the Medical Officer of Health or his deputies at Main Control during an air raid deal direct with first aid posts and hospitals—not through the divisional organization as they do in the case of ambulances and first aid parties. Early in the raid hospitals and first aid posts taking cases from the parts of the city which appear to be the main objects of attack are warned by telephone that they must shortly expect a large influx of casualties. We receive a daily return of the number of beds available for casualties at the various hospitals in the city and are therefore in a position to estimate, during the raid, the moment when particular hospitals are becoming overloaded and the ambulance depots should be instructed to switch casualties over to other hospitals. Sometimes a hospital or first aid post is damaged and can take no further casualties. One way in which a hospital may be put out of action without extensive damage occurring is when main water pipes or sewers are broken or when a time bomb falls near the main entrance; but fortunately, pipes and sewers can be replaced within forty-eight hours and time bombs rapidly rendered harmless. There have been occasions when, in the middle of the night, hospitals have had to be partly or completely evacuated because of the fall of a delayed action bomb near to some of the wards. The removal of seriously ill or injured patients in large numbers from one hospital to another during an air raid at night is a responsible undertaking, and to facilitate such removals we have converted a large number of single-decker

buses into ambulances, each capable of taking ten stretchers.

During an air raid of the kind we are considering, the emergency mortuary facilities will be fully employed. In Great Britain the standard of mortuary accommodation for target areas, as laid down by the Ministry of Health, is 3 places per 1,000 of the population. Mortuaries have been organized in some of the older schools and each possesses office facilities, viewing rooms, and a large space with racks for the accommodation of the dead. There is a Chief Mortuary Officer for the city and each mortuary has a superintendent, a clerical staff, and attendants. Needless to say, this kind of work is highly unpopular and it has been found difficult to recruit the necessary staff even if high wages are paid. I have been helped in connection with the staffing of this service by the clerical staff of the Corporation's departments, porters from hospitals, and medical students from the University who, naturally enough, have less objection to handling dead bodies than the average citizen.

During the raid and on the days following it the atmosphere at the emergency mortuaries is one of grim and unrelieved tragedy. Apart from the actual handling of bodies the greatest difficulty in connection with the mortuary service is that of identification. Some bodies are so injured that they cannot be identified with certainty, except by such indirect methods as the recognition by relatives of clothing or possessions. In some cases, of course, even that is not possible. In order to avoid the necessity of relatives viewing many bodies, the practice is followed of placing all articles found in the pockets of the deceased into a container marked with the same serial number as the body and, as a further help toward identification, strips of the outer clothing are taken and placed in the container. If there are letters, a national registra-

tion card, or an identity disc on the body at the time of death, and these are still available, the recognition of the deceased by relatives is rendered easy; but in many cases bodies cannot be identified at all and are buried in a common grave at a mass burial service. Questions in regard to presumption of death sometimes arise in relation to the disposal of property or to re-marriage and therefore from the legal point of view the mortuary records are of great importance. These records in Liverpool consist of a mortuary register, containing information in regard to serial number, date of reception of body, name of person (if known or ascertainable), age (if obtainable), sex, home address, cause of death (*i.e.*, falling masonry, bomb explosion, etc.), incident from which body was recovered, reference number of notification to friends or relatives, type of funeral arranged, date of burial, cemetery, section and grave number in which interment took place and signature of undertaker removing the body; property register containing an inventory of clothing and effects taken from the body; and various forms, including burial certificates, and in relation to funerals. Identified bodies can be claimed by relatives and buried privately—a grant being made by the Government toward the expense of burial in certain cases. In a proportion of cases relatives prefer the method of mass burial, and identified and unidentified bodies, each in a wooden coffin, are interred in vaults at our main cemetery, all religious denominations taking part in the communal ceremony.

The next line of action during an air raid is to transport persons rendered permanently or temporarily homeless by demolition of or damage to their houses to rest centers which have been established in convenient situations in all areas liable to bombing. Rest centers—a strictly temporary provision—are in Liverpool and other areas under the

administration of the Public Assistance Officer and have been established in schools, church halls, dance halls, large houses, etc. They are provided with elementary cooking facilities, mattresses, blankets, chairs and tables, cutlery and crockery, and sanitary arrangements sufficient for temporary use by large numbers of persons have to be improvised. Relays of food are provided as the frightened straggling parties arrive throughout the night, a nurse is on duty all night and a doctor visits the center, and an officer of the Public Assistance Department takes the names and addresses of families ready for the billeting officer when he visits the center after daybreak.

In the morning officers of the local authority—who have probably had no sleep themselves—appear to arrange billets or to provide money for immediate necessities. Billets are in private houses as a general rule, compulsory powers to billet being available; but local authorities have in some cases provided large furnished houses where difficult families can obtain shelter. As a result of experience, these arrangements became so efficient that rest centers were completely cleared in about 48 hours unless, as often happened, another air raid had occurred on the following night. The duration of stay in billets depended upon the amount of damage done to the various houses. Where the blast had not affected the main fabric of the house but had only damaged doors, windows, or roofs, first aid repairs might be completed in two or three weeks, and the family would then return to commence the unenviable task of cleaning the house and putting such furniture as had survived into usable condition.

Some families in Liverpool have been "bombed out" of the same house or successive houses three times or more and are becoming quite used to their stays in rest centers, billets or, as fre-

quently happens, in the houses of friends. Naturally the number of houses completely destroyed or so badly damaged as to be regarded as incapable of first aid repairs is much less than the number affected to a minor extent by blast; and families escaping from the disaster of a demolished or seriously damaged dwelling (usually because they were in a shelter) are difficult to provide for. Like other and more fortunate families, they are taken for the night to a rest center and later provided with billets which they may be required to occupy for months until one of the limited number of unoccupied houses in the city, of a size suited to their means, is available.

During the severe air raids last year the need for small working-class houses was so great that housing standards were relaxed and some dwellings condemned as unfit for habitation by the medical officer of health before the war and awaiting demolition were temporarily brought into service to accommodate the homeless. This action was, admittedly, not justifiable on public health grounds and is one out of many examples of reductions in the standards of hygiene rendered necessary by the categorical imperatives of war. The arrangements for the provision of food and shelter for persons bombed out of their homes should be carefully thought out beforehand in great detail, because upon their satisfactory working during air raids depends, to no small extent, the morale of the people, who will form their judgments of the efficiency of all the local authority's civil defense services largely upon their personal experiences in connection with rest centers and billets.

One of the most important provisions of a complete civil defense scheme for an urban area is a system of air raid shelters properly distributed according to population density in the various districts of the city, each shelter being

fitted with such requirements as heating, lighting, and ventilation so as to be reasonably comfortable during periods of prolonged occupation. Shelter policy in Great Britain, both during and prior to the war, has been the subject of prolonged and at times even acrimonious discussion between those who believed that a relative degree of safety could be secured by substantially built surface shelters and an important group who maintained that a much higher degree of safety was essential and that this standard could only be secured by deep underground shelters. Official opinion has remained strongly in favor of the former policy and, therefore, as far as ordinary domestic communal shelters are concerned, they are (unless local circumstances dictate another method, *e.g.*, tunnelling) surface shelters constructed of brick or concrete and of standard dimensions. There are many types, but the three main kinds of shelters are (1) public shelters, usually situated in strengthened basements under large buildings, intended originally for chance uses in daytime raids, but actually used during the first two years for night occupation; (2) domestic communal shelters, built in rows along one-half of the carriageway of side streets, and situated more or less opposite the houses occupied by the families for which they provide shelter; and (3) shelters of a special type, *e.g.*, the Morrison table shelter designed for use inside the house, the Anderson shelter for use in small gardens or yards and small brick or concrete one-family shelters. The public health department is mainly concerned with public shelters, but there are one or two observations to be made about the other types. Domestic communal shelters—by far the most numerous kind—are situated directly on the road and are commonly built of brick, the walls being 20 inches thick, the walls, roof, and floor being reinforced with steel bars.

They shelter 50 persons and are divided into three compartments, each with an entrance and a door which can be locked. Lighting and an electric heater which also acts as a ventilator are installed, but there are no sanitary conveniences, and water is not supplied as the shelters are close to the houses of the occupants. Some domestic communal shelters are fitted with metal bunks in two tiers but these are not popular except for use by small children and, of course, these fittings reduce the total capacity of the shelters. Difficulties are experienced in some parts of the city in persuading occupiers to keep the shelters allocated to them clean, and it has been necessary to appoint inspectors to deal with cleanliness in public and domestic communal shelters. However, it has been possible recently—in Liverpool—to reduce the number of these inspectors, as the standard of cleanliness has improved, and the provision of doors and locks and the allocation of a specified part of a shelter to each family have materially contributed to the care with which shelters are used—and also to the reduction of wilful damage. Infestation by lice and bed bugs of bedding (which is left in both public and domestic communal shelters during repeated air raids) has always proved a difficulty, and fumigation is required from time to time. Judging from experience of the use of domestic communal shelters of the standard design during a period of nine months of air raids, the verdict may justifiably be passed that they have provided a high degree of protection against blast and splinters (although not, of course, against a direct hit) and a reasonable standard of comfort for the occupants condemned to spend the greater part of a long night in them. They are cheaply built and, being situated near to the occupants' homes, can be quickly reached in a sudden raid and equally quickly vacated as occasion may require.

Public shelters afford protection to between 200 and 2,000 people. They are supplied with washing facilities and sanitary arrangements and light refreshments such as tea, coffee, cakes, and sandwiches are available at low prices. The daily cleaning of public shelters, after a night's occupation, is done by one of the departments of the local authority and, during air raids, shelter wardens are on duty to keep order and occasionally to settle disputes. Difficulties have been caused by a certain amount of drunkenness, and sometimes women of an undesirable character resort to the public shelters. In general, however, the standard of behavior has been good, and the regular occupants, of which there is a surprisingly large number, keep their bedding and belongings at the shelters for weeks or months at a time during air-raiding periods.

I have frequently asked occupants of public shelters why they are there, perhaps far from their homes, rather than in their local domestic communal shelters, and the impression one gets from questioning is that certain types of people, during dangerous periods, obtain a greater feeling of safety when surrounded by numbers of their fellows. There is also more going on at a public shelter as concerts or lectures are sometimes arranged, and the presence of a trained nurse and the visits of the doctor are matters of interest to many of the unsophisticated shelterers. The idea that public shelters are safer than domestic communal shelters is not a matter of fact but of feeling; and public shelters, packed with hundreds of people, are a source of continual anxiety to the administrative officers during air raids, since a direct hit by a large bomb, bringing down much of the building, may cause an enormous casualty list, whereas a bomb of similar size hitting a domestic communal shelter will have a much less damaging effect

because the number of persons is so much smaller. Dispersal is the fundamental principle for safety in air raids, and the occupation of very large public shelters, even if sub-divided into compartments, offends against this principle.

Medical arrangements in connection with public air raid shelters consist of a medical room with a sick-bay adjoining, mainly for isolation purposes, the attendance of a trained nurse throughout the night, and a visit of a medical practitioner to whom children suspected to be suffering from infectious diseases are referred for diagnosis and who, in addition, deals with various minor ailments which seem urgently to need treatment. It is no part of the doctor's duty to treat patients who could well be left to be seen by their own practitioners the next day. The principal reason for his visit and for the attendance of the nurse during the night is psychological, namely, to impart confidence to the occupants of the shelter.

The subject of special shelters, such as the Morrison and Anderson, can be briefly referred to. Both of these types are made of steel and are only supplied to local authorities in limited quantities at the present time, although in the case of the Anderson many were manufactured and distributed from 1938 onward before domestic communal shelters had been built in any numbers. The Anderson is an outside shelter and consists of thin corrugated iron, shaped in the form of a half cylinder, which is sunk in the ground to the depth of a few inches and its sides covered all over with sandbags or a foot of earth. Inside many of them have concrete seating and a concrete floor. On the other hand, the Morrison is an indoor shelter, six feet 6 inches long, and in appearance is like a steel table (and can be used as a table) with metal legs and strong wire mesh sides. Its provision is now restricted to persons who are badly crippled or permanently bed-ridden, a

medical certificate, which is strictly scrutinized, being required when applications are received by local authorities.

My last subject is that of day and residential nurseries which are being provided as rapidly as possible for the children of mothers who are engaged in the war factories or on other work of national importance. In many cases the children are looked after by a relative or a neighbor, but it seems obviously desirable on health grounds that as many children as possible under the age for compulsory attendance at school should be cared for, when their mothers are working, by the local authorities in circumstances which insure a satisfactory diet, medical and nursing supervision, and some preliminary education of an informal kind.

For the present at least these nurseries, of which about 800 have already been opened in England and Wales, must be regarded strictly as a war provision; but it is likely that after the war the system will be retained and expanded, mainly in the form of nursery schools and classes, *i.e.*, as part of the Education Service rather than the Public Health Service. Today nurseries are of three main types, namely, those caring for children between the ages of 0-2, 2-5, and residential nurseries. The requirements of mothers working in the war factories vary according to the periods of duty. If a woman is on the three shift system, or for any reason has to work at night, the ordinary nursery caring for children during the day only is of little use to her and she is compelled to have recourse to a residential nursery, of which not many have been established. In general, mothers with children under the age of 5 tend to apply for work in shops or in small factories where a night shift system is not in operation, and for them the day nurseries, open from about 7:30 A.M. to about 6:30 P.M. are an adequate provision. Nurseries established in

elementary school premises and catering to children between the ages of 2 and 5 are usually in charge of the head mistress who is assisted by girls who have had a short course of training; while

nurseries, either in school premises or in adapted houses, which care for children from 0 to 5 are under the control of a matron who is a trained nurse, and she is assisted by a teaching staff.

Food and Nutrition of the Industrial Worker in Wartime*

FRANK G. BOUDREAU, M.D., AND
ROBERT S. GOODHART, M.D.

*Executive Director, Milbank Memorial Fund, New York, N. Y., and Chairman,
Food and Nutrition Board, National Research Council; and Technical
Adviser, Industrial Nutrition, Office of Defense Health and Welfare
Services, Washington, D. C.*

THE importance of the nutrition of the industrial worker began to be appreciated in this country soon after the outbreak of war in 1939. The character of the war impressed upon us the fact that, perhaps for the first time in history, the responsibility for national defense was shared by every class in the community. Wars could no longer be left to the armed forces and to ordnance plants. Successful defense called for the use of every worker and of every resource in the community. Germany was successful in the first years of the war because she had geared the strength and resources of the entire community into the war effort. It was a war of production; of production needed to keep the community strong, as well as to furnish weapons for the armed forces. The lesson was quickly learned in Great Britain where programs of public health and nutrition were greatly expanded at the very time that the military situation was the most desperate. We have not yet learned this important lesson. Workers upon whose production depends the outcome of battles in distant seas, islands, and con-

tinents are still inadequately fed. In many cases no amount of education in diets would be of very much help, for conditions are such as to make it almost impossible for the worker to obtain a good diet.

It was Great Britain's example which aroused our interest in the subject. There the Ministry of Food decreed that there should be a canteen in every plant employing 250 or more workers. The basis for this action was to be found in a statement of Sir John Boyd Orr:

The improvement of the diet of workmen whose diet was not previously up to the standard for health is followed by increased output without any conscious increased effort and also by a reduction in the number of accidents. Many factories are now providing a meal for employees. It is likely that, as part of the national effort for increased output of war material, the provision of a meal will be made compulsory in all factories and measures be taken to ensure that the meal is on the lines of the Oslo breakfast, which will make good the deficiencies of the portion of the diet eaten at home.¹

The National Nutrition Conference for Defense, called by the President and held in Washington in May, 1941, adopted a series of recommendations on the diet and nutrition of the defense worker.² Perhaps its most important recommendation was that the approval

* Presented before a Joint Session of the Industrial Hygiene and Food and Nutrition Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 30, 1942.

of all contracts calling for the construction or expansion of defense plants should include consideration of appropriate facilities for feeding the workers. This was awkwardly worded but the intent was clear. Unfortunately it was never implemented. It is still possible to build a plant in an area where practically no community facilities exist and to make no proper arrangements for feeding the workers. The Conference also recommended that the families of low-income workers (in defense industries) should be included in the distribution of protective surplus foods; it emphasized the importance of conditioning labor recruits nutritionally; and it pointed to the need for controlled studies of diet and nutrition in their relationship to health, working capacity, incidence of accidents, and absenteeism.

The Committee on Nutrition in Industry of the National Research Council took up the challenge of the Conference. In the summer of 1941 Dr. Robert S. Goodhart, vice-chairman of the committee, visited and studied thirty-three defense industries throughout the country. His report made it clear that facilities for feeding the workers were inadequate or lacking in most of the plants; that it was difficult or impossible for the workers to obtain good diets by their own efforts; and that, even when proper foods were available, it was easier and cheaper to purchase meals of nutritionally inferior foods. A controlled study of the diets and nutritional status of approximately 1,500 workers in an airplane plant in the West was organized under the auspices of the committee, and plans were made to start similar studies in several different geographical areas. The committee published its first report *The Food and Nutrition of Industrial Workers in Wartime* in April, 1942,³ and copies were widely distributed, arousing keen interest among doctors, workers, and employers. Finally, in view of the interest aroused

and the fact that ways to attack the problem were becoming known, the Nutrition Division of the Office of Defense Health and Welfare Services decided to employ a technical consultant in the nutrition of industrial workers and to set up an organization to carry out the work throughout the country. The technical consultant in the Office in Washington is to work through representatives in each of the twelve federal security regions. At least one of these is a physician with some experience with industry and special knowledge of nutrition. Had it not been for the army's need for doctors, many more qualified physicians would have been employed.

In the meantime industry itself had taken a prominent part in the work. Requests for advice poured in from industrial management and medical departments. Several industries undertook carefully worked out programs of education in nutrition, both for the worker and the worker's family. These programs were "sold" to other industries and must have had considerable results. Industrial leaders in Bridgeport, Conn., joined with civic and defense authorities to demonstrate what could be done to improve the diets of industrial workers. The leaven has spread throughout the country, so that at present few industrial leaders can be unaware of the importance of proper food and nutrition for the worker.

When the Committee on Nutrition in Industry started its work, practically no information was available concerning the diets of industrial workers, little or nothing was known of their nutritional status, and no one had gone to the trouble of collecting information concerning the facilities for feeding workers available in war plants. The committee was forced to rely upon indirect evidence, and the advice of experts with practical experience. The committee's reasoning is found in its first published report. It was known that many war

plants were expanding rapidly and that many new plants were being built, some in sparsely settled areas with inadequate facilities for housing, food, and medical care. New workers were being employed and these came in large part from age groups and classes not suitable for the armed forces. Many of them had been unemployed, and the change from light or no work to fairly long hours of concentrated toil, with changing shifts and unaccustomed types of work, must have imposed a heavy strain upon bodies and minds which in so many cases were out of training.

The only available evidence concerning these new workers was derived from an investigation of the nutritional status of a WPA group in New York City. This group was engaged in clerical, messenger, and laboratory work, and had not been very effective, although on the whole competent and willing. Over 26 per cent of 165 adults of both sexes were found to be deficient in blood-plasma ascorbic acid with less than 0.20 mg. per cent. More than 40 per cent had less than 0.40, and over 55 per cent had less than 0.60 mg. per cent. As for the incidence of anemias, 7.6 per cent of the males had less than 14 gm. of hemoglobin per 100 ml. of blood, and 6.8 per cent of the females had less than 12 gm., the minimum limits of the normal range for males and females respectively.

The most common of the deficiencies was avitaminosis A, revealed by characteristic changes in the conjunctiva. Marked changes were found in the eyes in 65 of 143 persons examined, while only one of the entire group was classified as completely normal. In a number of the cases these changes in the conjunctiva have disappeared after long treatment with vitamin A, whereas they are still as marked as ever in a control group.

The committee viewed with some alarm the employment of such nutri-

tionally deficient persons in war plants; they were not likely to get into the armed forces. Hence it recommended that steps should be taken to condition nutritionally those classes of the population who are likely to become workers in war plants. In adopting this recommendation the committee had in mind the startling results obtained in Great Britain when volunteers who had been rejected by the army, mainly for underweight, debility, and deficient chest measurement, were conditioned at the Physical Development Depot at Canterbury.⁴ Nearly a thousand rejectees were built up for six months at this depot. Measures for improving the health of the unsuccessful recruits (this was in peacetime) included: 1, optimum diet; 2, long sound sleep; 3, hard physical work; 4, healthy recreation. Milk and fruit were added to the presumably adequate army ration. In addition to four regular meals, a snack was served at 10:30 a.m. (milk or soup and fruit), and the men had tea (tea, biscuits, and barley sugar) in the afternoon.

As a result of this conditioning, 87 per cent of 834 men so treated were accepted and passed into the army. Only 5 per cent were afterward discharged on grounds of medical defect.

This is certainly an economical and simple method of conserving badly needed man power. It could have been carried out easily in CCC camps as well as in NYA, WPA, and defense training schools. It is probable that these agencies have greatly contributed to the efficiency of the men, women, and boys with whom they have dealt. But it would have been well worth while to have made a more ambitious effort to condition, under medical and nutritional guidance, some of the weaker elements among those on whom we now depend for war production.

The committee also based its recommendations in part on the work of Williams, Wilder, and their coworkers,⁵

who showed that a diet sufficiently rich in thiamin to prevent the development of obvious deficiency disease is not necessarily adequate for the best nutritional state of the patient. Larger amounts of this vitamin in the diet increased the alertness and attentiveness of experimental subjects and led to more satisfactory performance on an exercising device; i.e., increased working capacity. Diets deficient in thiamin gave rise to clumsiness leading to numerous small accidents, such as finger cuts and broken dishes. Many authorities believe that thiamin is one of the commonest deficiencies in the American diet. Significant changes in the psychological state of the experimental subject have also been produced by decreasing or increasing the thiamin content of the diet.

The Committee on Nutrition in Industry has now in its possession many more facts concerning the diets and nutrition of industrial workers than were available to it in 1941. The vice-chairman of the committee brought back from his brief survey of thirty-three war plants a general picture of the facilities available for feeding workers in and around such plants, and some idea of what the men had for breakfast. In far too many cases the workers drove long distances to work with little or no breakfast. Sometimes they obtained breakfast at the plant cafeteria and more often than not selected dishes of little nutritional value. At luncheon some of the men ate in the cafeteria if one was available; their choice of dishes was poor in one-third to one-half of the cases. Workers who did not eat in the cafeteria had recourse to lunch boxes, which cause delays because they have to be inspected to prevent possible sabotage. But war plants with adequate cafeterias were almost unknown, and those which did exist did not help the workers to select a balanced meal. In fact, the worker who does select a good meal in the average plant cafeteria is

penalized by having to pay more than the usual price. Thus if the special meal recommended by the cafeteria costs 30 cents, a balanced meal exceeds that cost by varying amounts.

More precise data on workers' diets were furnished by a study of the diets of about 1,100 aircraft workers in Southern California.⁶ The report on this study has been elaborated in some detail and cannot be adequately summarized here. Over 55 per cent of the diets were classified as poor as regards consumption of green or yellow vegetables; nearly half were deficient as regards citrus fruit or tomatoes; about a third were poor in milk, a fifth in eggs, but almost all were satisfactory in the amount of lean meat consumed. Only 2 per cent of the diets contained satisfactory amounts of each of the five food groups, while 87 per cent of the diets had amounts definitely below those recommended by the Food and Nutrition Board of the National Research Council.

Two hundred and fifty complete two day diet records (the conclusions above refer to weekly diets) were analyzed to obtain approximate values for their nutritive content. The percentages of the diets in which the amounts of specific nutrients were less than two-thirds of the recommended daily allowances were: protein 0.8 per cent; iron 4.0 per cent; niacin 7.2 per cent; thiamin 14 per cent; vitamin A 14.8 per cent; calcium 24.8 per cent; riboflavin 43.2 per cent; ascorbic acid 46.0 per cent. There were 71.6 per cent of these diets which fell short of two-thirds of the daily allowance in one or more specific nutrients. It is surprising to find that 40 per cent of the men reported diets which furnished less than 140 per cent of basic metabolic needs, as this level of caloric intake is insufficient for men engaged in work involving physical activity.

The workers who reported these diets were medically examined to determine their nutritional status at the beginning

of the study. The results of these examinations have not yet undergone complete analysis, but Dr. Henry Borsook, director of the study, has reported some preliminary findings.⁷ Forty-two per cent of slightly less than 1,000 workers had less than 0.5 mg. per cent blood plasma ascorbic acid (17 per cent had less than 0.25 mg. per cent). Nineteen per cent showed signs of premature degeneration of the nervous system as evidenced by loss of vibratory sensation in the toes to a C-256 tuning fork. This is generally accepted as pathological in men under 35 years of age. Forty-seven per cent had localized, elevated conjunctival spots (Bitot's spots); evidence of vitamin A deficiency. Over 28 per cent had a blood hemoglobin content of less than 14 gm. per cent. Capillary invasion of the cornea of the type indicative of riboflavin deficiency was almost universal. The final report of this study will be of the greatest interest, as about half of the men are being treated for their nutritional deficiencies.

It may be noted, in the foregoing, that the percentage of nutritional deficiencies exceeded the percentage of diets deficient in particular nutrient. This is probably accounted for by losses of nutrients in processing, storage, cooking, and standing. Recent evidence on this subject tends to show that these losses are probably very great in practice; as high as 90 per cent in ascorbic acid.

The evidence that has been uncovered in these studies, few and incomplete as they are, cannot be glossed over. Each new survey reinforces and strengthens the case. The war workers, on whom we depend for production of the tools of war, are not adequately fed. A large proportion of them suffer from multiple but mild nutritional deficiencies. Under these conditions optimum health is impossible, and output must suffer accordingly. According to Dr. C. O. Sappington, time lost on account of illness is costing American industry ten billion

dollars a year. Dr. Victor G. Heiser states that ordinary disease such as prevails in the community is responsible for nearly fifteen times as much loss of time as trade hazards and accidents combined. No one knows how much of this absenteeism could be reduced by adequate diets, but every dietary experiment with workers, however incomplete, has shown beneficial results. Sound health cannot be maintained without an adequate diet, and health is the foundation of morale. Ivy⁸ states that work demands rest, good food, and wholesome recreation; that physical fitness is essential to sustained effort and output. The rôle of adequate diets in the armed forces should lead us to give equal consideration to the nutrition of our war workers who play so large a part in our defense.

Those who have not been in close touch with this subject can have no idea of the widespread interest among workers and their families, management, communities, and states. This growing interest has extended to industrial physicians who had been taught in the past that the diet and nutrition of workers did not come within the scope of their work. The American Association of Industrial Physicians has set up an active Committee on Nutrition in Industry. The Committee on Industrial Health and Medicine of the National Research Council has held joint sessions with the Committee on Nutrition in Industry, and has adopted all of the latter's recommendations.

Interest among other groups is just as widespread. State Defense Councils have devoted considerable attention to the subject; in New York State two full-time physicians trained in public health have been employed for the purpose of directing this work. State and local committees have organized subcommittees on nutrition in industry, many large plants have employed nutritionists and dietitians, and public

utilities have thrown some of their large resources into the campaign.

This widespread interest in the health and nutrition of the industrial worker gives the alert health department a golden opportunity to make its influence more widely and deeply felt. It gives the health officer a chance to widen the scope of his program; the industrial physician the opportunity to make his work much more effective. No longer is nutrition regarded as something for women and children, for now soldiers, sailors, and airmen as well as war workers come into the picture. We determined after the last war that steps would be taken to fill the gaps in our public health program revealed by the draft examinations. That our efforts were not very effective is shown by the results of present selective service and induction examinations. We should take every advantage of the new knowledge

and the new interest in the field of nutrition to move forward toward our goal, and to banish forever the assumption that dictatorships excel democracies in utilizing advances in science for the benefit of their people.

Fuel Oil Rationing Protects Public Health*

JOEL DEAN

*Director, Fuel Rationing Division, Office of Price Administration,
Washington, D. C.*

FUEL oil rationing is a positive program to protect public health against the potential ravages of the critical petroleum transportation shortage. Before the war 95 per cent of all petroleum consumed in the Eastern Area was supplied by tanker shipments. The toll of tankers by Axis submarines, plus diversion of tankers to war use, has reduced this form of transportation to a negligible quantity.

Because petroleum cannot be transported into the East by tankers in adequate quantities, every effort has been made to move petroleum by overland methods. All available tank cars, pipe lines, tank trucks, and barges on inland waterways have been put into service. However, in spite of tremendous increases in this form of petroleum shipment, thus far it has been impossible to supply the East with enough petroleum to fulfil minimum civilian and war production needs. As yet, the petroleum transportation shortage has not hurt the war effort. No war production plant has been forced to close down, nor has any airplane in the interceptor command been grounded for lack of gasoline. Your government hopes, by rationing and supply control, to prevent the fuel deficit from becoming so serious as to force choices among equally unpleasant

options—shut down of war production plants, inadequate supplies for the armed forces, or homes so cold as to endanger health.

To cope with this desperate war production and military supply situation and at the same time adequately safeguard public health, it was necessary to develop a rationing program which would attain several objectives. First, it should provide an effective stimulus to conserve fuel oil by improving burner efficiency, reducing structural heat loss, or converting heating plants to coal in order to make a positive contribution to the reduction of the fuel oil deficit. Second, it should curtail consumption to bring it into consonance with the petroleum transportation shortage and accomplish this curtailment in a fashion to assure equitable distribution of the available supplies. Third, it should take account of the special heating requirements of the young, the aged, and the ill.

Unless fuel oil is rationed and these objectives are attained, public health will be seriously jeopardized. Distribution of the woefully inadequate supply of this vital fluid by happenstance favoritism with no consideration for the high essentiality of hospitals or homes sheltering the ill, the aged, and the very young would result not only in cruel suffering but in an intolerable general health problem.

A positive incentive must be provided consumers to increase the amount of

* Presented before a Joint Session of the Health Officers and Engineering Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

heat and health they get from a gallon of fuel oil and thereby make an important contribution to the closing of the deficiency gap between a reduced supply and augmented requirements. This stimulus is provided by the rationing plan in the form of a differential cut depending upon thermal efficiency. Thus the wasteful user who has the greatest need and opportunity for improving thermal efficiency will be cut most, whereas the tight house that has few remaining opportunities to reduce fuel waste is curtailed least.

The effectiveness of this stimulus will be greatly increased if people are adequately advised as to how to improve their thermal efficiency. The public health officer and the medical profession are in a position to contribute importantly in passing on specific advice to consumers about ways of getting optimum health conditions from their fuel oil rations.

Insulation, storm windows and doors, and weather stripping will aid greatly in keeping heat where it will do the most good. An efficient burner properly adjusted, a carefully checked chimney, and a boiler or furnace, and heating pipes that are properly insulated will do much to get the most out of a limited ration by generating heat efficiently. In many cases this equipping and adjusting program will pay for itself in a very short time, not only in greater comfort and better health but in actual cash savings.

There are many other steps which the individual home owner can take to use his fuel ration most effectively. Unused rooms, such as extra bedrooms, and rooms that are notorious heat wasters, such as sun rooms, can be shut off completely. Radiators and registers should be shut off when windows are opened. Window shades can be lowered when light is not needed. Keeping draperies, or anything that interferes with circulation, away from radiators

will greatly increase the efficiency of the heating plant. Fireplaces can be closed off when not in use and thus prevent the escape of heated air. At other times, in mild weather, the fireplace will often provide sufficient heat without using the central heating plant. Great fuel economy results from lowering the temperature for at least 8 hours during the night. Many of these improvements and adjustments cost little or nothing except care and thought.

Under the ration plan, all uses of fuel oil and kerosene—whether for home heating, industrial, commercial, military, or miscellaneous—will be regulated. Every purchase of fuel oil will require the presentation of coupons or equivalent evidences secured from local War Price and Rationing Boards. Only heating uses, however, will be restricted.

In determining the basic home fuel oil ration, the following factors are considered for a private dwelling: (1) a standard heat-loss formula, based on the square foot dwelling area to be heated; (2) the previous heating season's consumption, adjusted for normal weather; (3) the number of occupants in each house. The ration will be affected by the normal temperature of the area in which the establishment is located by the use of a degree day temperature table for each area. The United States Weather Bureau has supplied the degree day information for our use.

The heat loss formula considers the heating requirements of a typical free standing house, possessing standard insulation and burner efficiency under the normal degree day temperature of the area in which it is located. By using two constants, the formula will set a ration range, which makes it possible to classify homes according to thermal efficiency and vary the ration in a way to stimulate improvement in efficiency. If $66\frac{2}{3}$ per cent of last year's adjusted consumption falls within the formula range, this amount of fuel oil will con-

stitute the ration. If the fuel oil allowance estimated on this percentage basis falls above the range, the maximum of the range will be taken as the ration. If it falls below, then 85 per cent of last year's adjusted consumption, or the minimum of the range, whichever is smaller, will constitute the ration. The formula for determining the ration will not presuppose the achievement of any particular temperature. The temperature inside the dwelling will depend upon the supply of fuel oil available and upon the individual consumer's preference for a higher or a lower temperature for a shorter or a longer period of time.

The individual ration, of course, will be determined by local War Price and Rationing Boards. The basic application blanks will contain the information necessary for the board to determine the ration. Consumers were urged to fill their tanks before the program started. The board will therefore assume that most private houses had full tanks on October 1, and will require additional evidence if the consumer states that his tank was not full. If this evidence is satisfactory, the ration will be tailored to the amount of the actual October 1 inventory.

The heating season has been divided into five periods of approximately equal degree days, and the rationed area has been divided into four thermal zones. Since the calendar distribution of degree days varies from thermal zone to thermal zone, the dates of the heating periods will be different for each thermal zone. Coupons are numbered to indicate the period in which they are valid. The value of the coupons can be changed from period to period to meet unusual weather conditions and unusual factors of supply.

Of particular interest to your group is the provision that has been made for supplemental or auxiliary rations. These may be granted by War Price and Rationing Boards upon demonstration that

a special hardship would result from using the basic ration alone. Under the plan, special provision is made for persons of poor health, those of tender or advanced age who require warmer temperatures. In the case of children, if they are under 4 years of age, that factor alone will be considered justification for rations to heat the home slightly above the average. Where there is sickness or old age, the eligibility for supplemental rations will be determined by certification or prescription of a licensed physician.

This provision places a grave responsibility upon the medical profession. Whenever it is necessary to provide special rations to meet unusual situations there is danger of laxity growing out of misunderstanding of the seriousness of the trust. The laxity in discharging this responsibility will be perilous to public health. The medical profession in certifying to auxiliary rations must guard the health not only of the applicants but also of those who are not eligible for special consideration but whose ration will be reduced if the privilege is abused by others. Abuse of this privilege can undermine confidence not only in the rationing administration but also in the medical profession, and can thereby break down the effectiveness of the entire rationing program. We know that we can depend on your profession effectively to bring to the attention of those members who may tend to be lax and over-generous the fact that not only the rationing program but the nation's entire war effort would be endangered if serious abuses were permitted.

As an aid to you and to your neighbors on the rationing board in assuring effective administration of this provision, a local review committee composed of the public health officer and two members of the medical profession will be selected by the county medical association in most rationed communities.

I am confident that we will receive the active support of the public health and medical profession in this positive program to protect the public health in the face of the critical petroleum supply deficiency. We have sought and followed the advice of the medical profession throughout the development of the

rationing program. We are still seeking your advice. If you feel, at any time, that the plan or its administration can be improved, feel free to tell us so. We want your counsel whenever possible, for we know that the interchange of ideas is necessary to successful waging of the war on the home front.

Etiology of Acute Illness Among Workers Using Low-grade Stained Cotton*

ROY SCHNEITER, PAUL A. NEAL, M.D., F.A.P.H.A.,
AND BARBARA H. CAMINITA

*Associate Bacteriologist; Chief, Research Section; and Junior Bacteriologist,
National Institute of Health, U. S. Public Health Service, Bethesda, Md.*

THIS paper presents the results of a further investigation of the etiology of an acute illness among workers using low-grade stained cotton. This illness has been previously reported¹ as occurring among workers in rural mattress making centers, cotton mills, cotton seed processing plants, and upholstering plants, where a very low grade of dusty stained cotton of the 1940 crop was used. Since April, 1941, reports of outbreaks of this illness have been received from 25 states and 2 Canadian provinces, with more than 700 cases reported in one state alone. Illness occurred among workers exposed to high dust concentrations and the severity of the illness varied with the degree of exposure. This disease is characterized by its sudden onset, 1-6 hours after exposure, and the short duration of the acute phase, usually 24-48 hours after exposure. The principal subjective symptoms are conjunctival irritation, substernal oppression, dryness of throat, generalized aches, fatigue, headache, cough, chills, fever, anorexia, nausea, and vomiting.

INVESTIGATION INTO THE CAUSE OF OUTBREAKS

During the course of this investiga-

tion, 115 samples of cotton, cotton dust, linters, cotton plant debris, cotton seed and soil were received from 14 states, the U. S. Department of Agriculture, and 2 Canadian provinces. These samples are listed in Table 1.

All the samples of cotton incriminated in outbreaks of illness were dusty, low grade and stained, and contained varying amounts of plant debris. The majority of these samples were classified within official grades for tinged and stained cotton by graders of the U. S. Department of Agriculture, and many of them were described as "bolly"² in character."

Preliminary chemical studies failed to reveal any extractable fractions, toxic gases, or insecticides present in the cotton which would be capable of causing illness.

MICROBIOLOGICAL STUDIES

The low incidence of fungi and the infrequent occurrence of pathogenic types of fungi in specimens of stained cotton precluded this class of microorganisms as the cause of the illness.¹

A microscopic examination of fibers of the stained cotton in moist preparations demonstrated the presence of rod-shaped microorganisms in mucilaginous clumps along the sides of the individual fibers. Fibers of stained and of normal cotton were stained by Gram's method and mounted in balsam. The fibers of

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

FIGURE 1—Microorganism in Lumen of Stained Cotton Fiber, Gram's Stain

stained cotton were seen to be thin-walled and to contain many short, rod-shaped bacteria within the lumen,¹ whereas the fibers of normal cotton were thick-walled and free of bacteria (Figure 1).

A quantitative bacteriological examination was made of all samples of cotton and other materials received for investigation. A 1:100 dilution of each sample was prepared by aseptically weighing 1 gram of material into 100 ml. of sterile physiological saline in wide-mouth, screw-cap bottles. The bottles were agitated mechanically for 20 minutes. Serial dilutions from 1:1,000 to 1:100,000,000 were made from the resulting suspensions. These dilutions were plated on potato-carrot-dextrose agar.* Inoculated plates were incubated 24 hours at 37° C. The plates

from all samples of stained cotton showed a heavy growth of large, colorless to pale yellow mucoid, spreading colonies to the exclusion of significant numbers of other types of bacteria (Figure 2). Microscopic examination of isolated colonies showed that the predominating microorganism was a Gram-negative rod. The incidence of this type of microorganism in the various materials examined is shown in Table 1.

Mucoid microorganisms predominated in 73 of the 74 samples of stained cotton from lots known or suspected to have caused illness. The plate counts of mucoid bacteria in these 74 samples ranged from 4,000 to over 5,000,000,000 per gm. of cotton. The same strain of mucoid bacterium, determined biochemically, was isolated from 65 of these 74 samples. This strain or type culture will be referred to in this paper for convenience as the "cotton bacterium." The "cotton bacterium" was also isolated from 3 of 8 samples of

* Formula: Potatoes, 2,000 gm.; carrots, 500 gm.; dextrose, 200 gm.; magnesium sulfate, 5.0 gm.; sodium carbonate, 2.0 gm.; agar, 150 gm.; and water, 10 liters. pH adjusted to 6.8.

TABLE 1

Bacteriological Examination of Samples of Material Relative to Acute Illness

<i>Type of Material Examined</i>	<i>Total No. of Samples</i>	<i>No. of Samples Containing the Cotton Bacterium</i>	<i>Average Plate Count of Mucoïd Bacteria per gram</i>
<i>Reported or Suspected to Have Caused Illness:</i>			
Tinged or stained cotton	74	65	678,000,000
Cotton mill dust	3	2 *	5,739,000,000
Bolly cotton seed as it reaches the seed oil plant	2	1 *	38,658,000
Bolly cotton as it reaches the gin	2	2	48,000,000
<i>Obtained from Plants Where Mill Fever or Grain Fever Had Occurred:</i>			
Cotton mill dust	4	3 *	36,125,000
Elevator screenings (grain dust)	4	4	18,150,000
<i>Not Known to Have Caused Illness:</i>			
Stained cotton, various grades obtained from miscellaneous sources	5	2	399,000,000
Stained cotton, various grades, obtained from U. S. Dept. Agriculture for comparison	5	5	159,221,000
Tinged cotton, various grades, obtained from U. S. Dept. Agriculture for comparison	5	2	1,021,000
Tinged or stained cotton, history unknown	3	1	51,700
White cotton, obtained from U. S. Dept. Agriculture for comparison †	9	0	118,000
Soil from ranch on which bolly cotton was grown	2	0	600,000
Cotton plant debris from field of plants infected with angular leaf spot	1	0
Hemp dust collected around a tow shaker in a hemp mill	1	1	1,020,000
Hemp plants, root, stem, leaves and blossom of Kentucky and of Chilean hemp	2	0	5,000

* An aberrant strain of the mucoïd "cotton bacterium" was isolated from the rest of the samples in this classification.

† Included in this group are the 2 samples of high grade cotton used as controls in the experimental work.

stained cotton reported not to have caused illness or on which the history was unknown.

The cotton bacterium was not recovered from the two control samples of high grade white cotton which were used throughout this investigation. The plate counts of miscellaneous microorganisms on these two samples were 13,000 and 110,000 per gm. respectively.

In order to determine the distribution of the cotton bacterium in different grades of cotton, 17 samples representing practically all grades of white, tinged, and yellow stained cotton were obtained from the U. S. Department of Agriculture. The presence of the cotton bacterium was demonstrated in all grades of yellow stained cotton and in two samples of the tinged cotton. The

FIGURE 2—Incidence of Mucoïd Bacterium in Dilutions of 1:1,000,000, 1:10,000,000 and 1:100,000,000 from a Sample of Stained Cotton

incidence of this microorganism ranged from 1,000 to 670,000,000 per gm. It was not demonstrated in any of the grades of white cotton or in four of the grades of tinged cotton examined. The results of these examinations indicate a possible wide distribution of the cotton bacterium in low-grade tinged and yellow-stained types of cotton.

A sample of cotton collected in 1938 from a cotton mill in which a severe outbreak of "mill fever"³ had occurred contained this microorganism in excess of 3,000,000 per gm. 3 years after collection.

An intact bale of low-grade stained cotton was obtained from a rural mattress making center in which a severe outbreak of acute illness had occurred. The incidence of the cotton bacterium in this cotton at the time of receipt was 1,100,000,000 per gm. (average of 5 analyses). At the end of one year of storage, the numbers of viable mucoid microorganisms had decreased to 470,000,000 per gm. of cotton.

Two dust samples from a cotton mill and 1 sample from a cotton seed plant in which several cases of this acute illness had occurred revealed the incidence of the mucoid organisms to be 1,200,000,000, 16,000,000,000, and 18,000,000 per gm. respectively. Four samples of dust from cotton mills in which this unnamed illness had not been reported but in which cases of mill fever had previously occurred showed an incidence of mucoid organisms in excess of 1,000,000 per gm. The cotton bacterium was isolated from 3 of these samples.

In connection with a severe outbreak of this illness in one cotton seed processing plant, it was possible to obtain specimens of (a) the soil in which the cotton had grown, (b) intact bolls from cotton plants in the same field in which the incriminated cotton had grown, (c) cotton seed from the plant, (d) cotton lint, and (e) rafter dust

from the linting room of the cotton seed plant. The typical cotton bacterium was isolated from the intact bolls and the cotton seed. An aberrant strain was isolated from the lint and rafter dust. The field soil did not contain this type of organism. The incidence of this general type of mucoid microorganism in these specimens was as follows: cotton from intact bolls, 3,800 to 54,000,000; cotton seed, 1,400,000 to 77,000,000; lint, 14,000,000; and rafter dust, 18,000,000 per gram of material.

This acute illness is similar to heckling fever, mill fever, hemp fever, and grain fever reported in workers inhaling flax, jute, hemp, or grain dust respectively. During these studies it was possible to obtain 4 samples of elevator dust screenings collected in a center where grain fever has occurred and a sample of hemp dust collected around a tow shaker machine in a hemp mill. The typical cotton bacterium was isolated from all of these samples.

Two hundred and fifty representative cultures of the predominating microorganism present in the material under investigation were isolated and purified for further study.

A microscopic examination of all cultures demonstrated that the predominating microorganism was a Gram-negative rod averaging $2 \times 0.7 \mu$, heavily encapsulated and actively motile in hanging drop preparations.

All purified cultures were subjected to an extensive series of biochemical studies for purposes of identification and classification. The basic medium employed for the fermentation studies contained 3 gm. of meat extract, 10 gm. of Bacto-proteose peptone No. 3, 5 gm. of C.P. sodium chloride, 0.02 gm. of phenol red or brom thymol blue indicator, and 5 gm. of the fermentable substance per liter. Final pH was 7.4. This medium was used in Durham fermentation tubes.

All observations on fermentation and

other tests requiring prolonged incubation were made after 24 hours and 7 days. Where reaction developed slowly a 21 day incubation period was used.

Cultures of the mucoid microorganism giving identical biochemical reactions were isolated from 70 of the 81 samples of stained cotton or other materials incriminated in outbreaks of this acute illness, as well as from 17 of 29 samples of stained or tinged cotton and other materials not incriminated in outbreaks of the illness. Aberrant strains of this microorganism were isolated from 10 of the samples in which the typical cotton bacterium could not be demonstrated.

The typical morphological characteristics and biochemical reactions of the cotton bacterium are listed in Table 2.

On the basis of its morphological characteristics and its biochemical reactions, the cotton bacterium has been tentatively placed in the genus *Aerobacter*.

PATHOGENICITY AND TOXICITY TESTS

Recovery of cotton bacterium from

cases of illness—Blood specimens and nose and throat swab cultures were obtained from approximately 40 individuals, who had contracted this sickness and from 10 control individuals, who had not had the disease. The cotton bacterium was never isolated from blood cultures obtained from cases nor from nose and throat swab cultures except in a limited number of cases in which the swabs were taken during or immediately after the illness.

Pathogenicity of cotton bacterium to animals—A series of experiments was carried out with animals to determine the pathogenicity of the cotton bacterium and the toxicity of filtrates obtained from broth cultures of this organism and from saline extracts of stained cotton. One to two ml. of these filtrates were the minimum quantities required to kill rabbits weighing 1.5 to 2.0 kg. The intranasal application of the cotton bacterium in several species of animals did not produce any ill effects. Massive doses of cotton bacterium cultures and culture filtrates were required to kill mice and guinea pigs when injected intraperitoneally.

TABLE 3

Dolman and Hammon Tests for Toxin

Dolman and Hammon tests for enterotoxin—A gastrointestinal upset, accompanied by nausea, vomiting, and sometimes diarrhea, were among the symptoms occurring in cases of this illness. It, therefore, seemed advisable to test filtrates from broth cultures of the cotton bacterium and saline extracts of stained cotton by recognized tests for the detection of enterotoxin.

One of the most widely accepted tests for the detection of staphylococcus enterotoxin is the intra-abdominal kitten test, first described by Dolman, Wilson, and Cockcroft.⁶ This test involves the intraperitoneal injection of 3.0–5.0 ml. of specially prepared culture filtrates into young kittens after the inactivation of lethal exotoxins by heat, formalin, or by neutralization by specific antitoxin. After a variable period of time, enterotoxic filtrates produced vomiting and diarrhea.

Hammon⁷ recently reported an improved intravenous injection method, which is claimed to eliminate non-specific or false positive reactions due to peritoneal irritation. In performing this test, the test materials are injected into the saphenous vein of the leg of mature cats without anesthesia. The

dosage varies from 0.5 ml. to 5.0 ml. depending upon the potency of the toxin. The toxic filtrates must, of course, be treated to inactivate the lethal factors before injection.

Cats weighing 600 to 1,400 gm. were employed in these tests. All culture filtrates and cotton extract filtrates were heated to boiling for 20 minutes before injection.

The dosages employed and the results obtained with each method of administration are recorded in Table 3.

These tests demonstrated that Berkefeld filtrates from 7 day tryptose broth cultures of the cotton bacterium and saline extracts of stained cotton contained heat-stable toxic substances capable of inducing vomiting and diarrhea in cats. Gastrointestinal symptoms were not induced in the control animals either through the intravenous or intraperitoneal injection of sterile tryptose broth or Berkefeld filtrates from saline extracts of normal cotton.

Pathogenicity of the cotton bacterium on cotton seedlings—In order to ascertain whether the cotton bacterium was capable of infecting cotton plants, cotton seedlings were grown in large flower pots that had been swabbed with mer-

cury bichloride, dried, and filled with sterilized top soil. The cotton seed used was examined for contaminants before planting. Sterile battery jars were used to cover the germinating seed and to insure a humid atmosphere.

Seedlings grown from seed that had been incubated in a tryptose broth culture of the cotton bacterium for 24 hours at 37° C. immediately before planting and seedlings that were irrigated with broth cultures of the cotton bacterium appeared to be normal and like the control plants over a period of one month. The leaves of normal seedlings, cleansed by swabbing with alcohol and inoculated by a needle prick or by rubbing a broth culture of the cotton bacterium on the underside of the leaves, did not develop lesions. Positive control plants similarly inoculated with *Phytophthora malvacearum* developed leaf spots. Negative controls treated with physiological saline and with sterile tryptose broth did not develop lesions.

The cotton bacterium could not be recovered from the leaves of cotton seedlings one month after inoculation; however, it was recovered from top soil

three months after inoculation. As a result of these tests, it was concluded that the cotton bacterium is not pathogenic for cotton seedlings under the conditions of these experiments.

Hopkins⁴ described two species of bacteria causing an internal rot of cotton bolls. From the meager descriptions given, it appears that one of these microorganisms is similar to the typical cotton bacterium which has been isolated during this investigation. He states that these bacteria are capable of decomposing and staining the immature cotton fibers within the boll. Other portions of the cotton plant are not attacked.

SEROLOGICAL STUDIES

Because this acute disease resembles an intoxication rather than an infection and because of the high incidence of the cotton bacterium in stained cotton to the exclusion of other miscellaneous types of microorganisms, the following serological studies were undertaken to ascertain whether the cotton bacterium liberated a toxic substance which might be capable of inducing the symptom complex.

FIGURE 3—Necrotic Areas Denote Positive Shwartzman Reactions Produced by Berkefeld Filtrates from 48 hour and 7 day Tryptose Broth Cultures of the Cotton Bacterium

*Shwartzman reaction*⁵—This reaction, using mature rabbits as the test animals, is employed to demonstrate "the phenomenon of local skin reactivity to certain toxic substances." These substances are generally derived from bacteria. In demonstrating this phenomenon, sensitivity is induced by intradermal injections (preparatory injections) of 0.25 to 0.5 ml. of the toxic substances. Reactivity is induced by intravenous injections (reacting injections) of 1.0 to 3.0 ml. of the toxic filtrates per kg. body weight, 24 hours after the preparatory injections. A positive Shwartzman reaction is evidenced by a severe hemorrhagic necrosis, usually beginning within 4 hours after the reacting injection at the site of the intradermal injection. These sites become swollen and dark blue with a red border. A typical positive Shwartzman reaction is shown in Figure 3. Animals are prepared for test by clipping or by epilating the skin of the flank with barium sulfide 24 hours prior to the initial injection.

The material tested in these studies included heated and unheated Berke-

feld filtrates from 7 day tryptose broth cultures of the cotton bacterium, heated and unheated filtrates from saline extracts of stained cotton, and filtrates from saline extracts of normal cotton. Sterile tryptose broth and sterile physiological saline (0.85 per cent NaCl) were employed as control solutions.

The results of a representative series of Shwartzman tests are shown in Table 4.

These experiments revealed the following: (a) A heat-stable endotoxin-like substance is liberated by the mucoid cotton bacterium; (b) a similar toxic substance is present in filtrates from saline extracts of stained cotton incriminated in outbreaks of illness; (c) that rabbits may be cross sensitized with filtrates from either source; and (d) that this endotoxic substance is not present in filtrates from saline extracts of normal cotton, in sterile tryptose broth or physiological saline.

It was also demonstrated by the Shwartzman reaction that homologous immune sera prepared through rabbit immunization with culture filtrates of the mucoid cotton bacterium, and with

F = Berkefeld filtrate from saline extract of stained cotton

G = Berkefeld filtrate from saline extract of good cotton

T = sterile tryptose broth (Bacto)

saline extracts of stained cotton contained antibodies capable of neutralizing the endotoxin-like substance present in these materials.

Agglutination tests—These tests were employed to determine (a) whether antibodies are produced in human or animal serum in response to the introduction into the body of viable or killed cultures of the cotton bacterium, filtrates of broth cultures (endotoxin) of the bacterium, and filtrates from saline extracts of stained cotton, (b) whether antibodies for the cotton bacterium are present in normal human or animal serum, from individuals not known to have had this illness or animals which have not received immunizing injections, (c) whether antibodies are produced in rabbits, in response to the introduction of filtrates from saline extracts of normal cotton, free from the cotton bacterium.

The sera tested were as follows: (a) human sera obtained from individuals in several states who had had the acute illness 24 hours to several weeks prior to the time of obtaining the sera; (b) sera obtained from 4 baboons at known intervals after a 7 hour exposure to stained cotton, (c) sera obtained from rabbits given repeated, intermittent, intravenous injections of saline suspensions of viable and killed organisms, Berkefeld filtrates from 24 and 48 hour and 7 day tryptose broth cultures of these organisms, and filtrates from saline extracts of stained cotton, (d) control sera obtained from individuals not known to have had the illness, from 1 baboon not exposed to stained cotton dust, from a rabbit injected with a filtrate of a saline extract of normal cotton, and from a normal non-immunized rabbit.

The antigens used for these tests consisted of filtered, standardized uniform suspensions of 18–24 hour potato-carrot-dextrose agar slant cultures of the typical bacterium isolated from cotton

samples which had been implicated in outbreaks of the acute illness.

The *method* consisted of diluting the serum in the usual manner with sterile physiological saline throughout a range from 1–10 to 1–5,120; 0.5 ml. of antigen was added to each dilution and after thorough mixing, all agglutination tubes were incubated in a constant temperature bath at 37° C. for 2 hours, followed by refrigeration at 5° C. overnight. Many of the human sera, including some of the controls, and all baboon sera contained variable low titer agglutinins for the cotton bacterium. The explanation for this fact is unknown. However, it would seem to indicate that because the cotton bacterium is closely related to certain types of bacteria commonly found in the intestinal tract of primates, it may be agglutinated by their antibodies. It would also indicate that a marked production of antibodies in the blood is not stimulated by exposure to the cotton bacterium or its toxic products, under the conditions described herein.

Identical antibodies, *i.e.*, antibodies capable of agglutinating typical culture antigens of the cotton bacterium, were produced in rabbit blood through immunizing injections with all saline suspensions of viable and killed organisms, by Berkefeld filtrates from 24 and 48 hour and 7 day tryptose broth cultures, and by filtrates from saline extracts of stained cotton. No agglutinins for the cotton bacterium were produced by those rabbits injected with filtrates from saline extracts of normal cotton, nor were such agglutinins present in the blood serum of normal non-immunized rabbits. The maximum agglutinin titers of these immune sera for typical cultures of the cotton bacterium are shown in Table 5.

Each animal was bled and the agglutinin titer of the immune serum was checked at intervals throughout a period of one year. There was a tend-

* The first test was carried out before immunization was complete

ency for the titer of the serum to decrease gradually with increasing length of time after the last injection of the antigen. This is shown in Tables 6 and 7, which show the decrease in the agglutinin titer of the immune sera obtained through immunization with culture filtrates of the typical cotton bacterium and with filtrates from a saline extract of stained cotton. These immune sera were utilized to separate the cultures isolated from the cotton samples into a number of serological groups. These tests demonstrated that the majority of the organisms isolated from stained cotton belonged to the same, or closely related serological groups.

Precipitation tests—These tests were carried out with two of the types of blood serum available for this investigation, *i.e.*, human and rabbit sera, which were obtained or prepared as described under the general discussion of agglutination tests. These studies were undertaken in order to ascertain whether blood sera from human cases of this illness or rabbit immune sera, prepared as previously described, contained antibodies capable of precipitating pre-

cipitinogens prepared from cultures of the cotton bacterium and saline extracts of stained cotton.

Two precipitinogens were employed for these tests. One was prepared from an 18 hour tryptose broth type culture of the cotton bacterium by Lancefield's⁸ method; the other was prepared from a physiological saline extract of stained cotton by filtration through a Berkefeld N-candle and concentration by vacuum distillation at 30–32° C.

The procedure for these tests consisted in placing 0.2 ml. of undiluted serum in the bottom of each of nine 3 mm. tubes. Four-tenths ml. of the antigen, both undiluted and that diluted with sterile physiologic saline, over a range of 1:5 to 1:320 was then laid over the serum with a capillary pipette. One tube containing 0.4 ml. of undiluted antigen and 0.2 ml. of physiologic saline and a second tube containing 0.2 ml. of serum and 0.4 ml. of physiologic saline were prepared for controls. The tubes were incubated for 30 minutes at room temperature and then observed for ring formation. Incubation was continued for 2 hours at

* These serum Nos. refer to the same rabbit sera listed in Table 5. Serum nonphenolated.

37° C., the tubes then thoroughly agitated and stored at 5° C. overnight. Final examination for precipitates was then made.

Most of the human sera, including the controls, gave positive precipitation tests in low dilutions with both precipitinogens. Rabbit sera from normal non-immunized animals and from the animals injected with filtrates from a saline extract of normal cotton did not show any significant precipitin titer. All other rabbit sera gave positive precipitation tests with both precipitinogens. The results of the precipitation tests with rabbit sera are shown in Table 8.

The results of these tests indicate (a) that sera from rabbits immunized with viable or killed cultures of the cotton bacterium, Berkefeld filtrates from tryptose broth cultures of this organism, or with filtrates from saline extracts of stained cotton, contain high titer precipitins for the precipitinogenic substance in the cotton bacterium, and (b) that stained cotton contained an extractable substance which is precipitated by these immune sera.

BIOLOGICAL STUDIES

Animal exposure tests—Animal exposure experiments were undertaken in an attempt to discover some species of animal susceptible to this acute disease, which appeared to be due to the endotoxin-like substance present in stained cotton.¹ Baboons, kittens, hamsters, guinea pigs, monkeys, rabbits, and chickens were exposed to various types of cotton dusts for one or more 7 hour periods. While three of the baboons exposed to unsterilized stained cotton developed mild symptoms of the disease, none of the other animals exhibited any symptoms. It was concluded from the results of all animal exposure tests that none of the common experimental animals are very susceptible to this unnamed illness.

Human exposure experiments—Since this illness could not be definitely produced in any of the species of laboratory animals tested, human exposure experiments were undertaken. These experiments have already been reported in detail¹; hence they are only summarized at this time. Three test individuals were exposed for 10 minutes to each type of cotton dust investigated. Two control individuals were exposed to normal cotton dust for 10 minutes on every occasion when the test individuals were exposed to other types of cotton. A week or more was allowed to elapse between the exposures to each type of cotton material. Each individual was given a complete physical examination prior to each exposure. Records were kept of the temperature, pulse rate, respiratory rate, changes in blood picture, and development of symptoms.

The three test individuals did not reveal any signs or symptoms after exposure to normal cotton, nor did the two control subjects, who were repeatedly exposed to normal cotton dust under the same conditions, show any signs or symptoms incident to such exposure. Two of the test individuals developed minor symptoms of illness subsequent to exposure to sterilized stained cotton. It is thought that these mild symptoms were due to minute quantities of the heat-stable endotoxin, which were not destroyed by sterilization.

The same type of disabling illness was produced experimentally in the three test individuals by inhalation of (a) dust from normal cotton contaminated with the cotton bacterium and its products, and (b) dust from stained cotton containing a high incidence of the cotton bacterium. This illness was characterized by its sudden onset, 1½ to 3 hours after exposure, its short duration, i.e., 24–72 hours, and sudden high leucocytosis with a moderate increase in band and segmented cells.

One test individual was exposed for

one minute to a fine mist of a sterile Berkefeld filtrate from a 7 day tryptose broth culture of the cotton bacterium several weeks after exposure to the stained cotton dust. Symptoms of illness began within 45 minutes. Signs and symptoms were identical in type, severity, and duration with those noted after exposure to the dust from stained cotton. The exposure of four individuals for one minute to a fine mist of sterile tryptose broth of the same type as employed for toxin production by the cotton bacterium failed to produce any signs or symptoms of illness.

It is evident that the illness following these exposures was caused by the endotoxin-like products of the cotton bacterium. The symptoms of this illness were similar to those reported in outbreaks of illness occurring among workers in industries using low-grade stained cotton.

The three individuals who had experienced repeated attacks of experimentally induced illness through exposure to contaminated or stained cotton dust and the two control individuals who had been repeatedly exposed to the dust from normal cotton were given intradermal injections with 0.1 ml. of the test materials.

Berkefeld filtrates from broth cultures of the cotton bacterium and from the saline extracts of stained cotton caused severe skin reactions and systemic symptoms within 3 hours in the individuals who had been exposed to normal cotton dust, as well as in the three individuals who had experienced attacks of illness. These reactions were characterized by marked erythematous swelling, which was extremely painful on pressure. The three test individuals and one control subject experienced headache and generalized muscular pains within 10 hours. Two of the test subjects and one control subject had a severe lymphangitis and lymphadenitis of the arm. None of the five individuals

developed any significant skin reaction following the intradermal injections of sterile tryptose broth, sterile physiological saline, or the filtrates from the saline extract of normal cotton. The nature of the skin reactions denoted a definite intoxication rather than a sensitization to the substances injected.

DISCUSSION

As previously discussed,¹ the symptomatology and other findings encountered in an acute illness among workers using low-grade stained cotton except for their greater severity are similar to those in the so-called mill fever and Monday fever found in cotton mill workers. These diseases follow the inhalation of cotton dust. While the cause of these diseases has never been completely explained, they have been attributed to (a) the action of the cotton dust on the mucous membranes of the respiratory passages,⁹ (b) histamine⁹ present in cotton dust, and (c) to the irritating soluble proteins present in microscopic particles of cotton dust.¹⁰

Mill fever has never been attributed to bacteria or their toxic products. However, the British Departmental Committee on Dust in Cardrooms in the Cotton Industry in 1932⁹ reported the presence of large numbers of Gram-negative bacilli in cotton dust. No importance was attributed to these bacteria since no factor common to the bacteriology of the dust and the patients' sputum was found.

From the results of the work in this laboratory, it seems logical to assume that the toxic products of the cotton bacterium responsible for illness among workers in rural mattress making centers and in cotton seed plants using low-grade stained cotton, may also be the etiologic agent responsible for mill fever or Monday fever.

SUMMARY AND CONCLUSIONS

The results of a further investigation

into the etiology of an acute illness among workers using low-grade, stained cotton are presented.

One hundred and twenty-two samples of stained, tinged, and normal cotton, cotton dust, linters, cotton seed, soil, hemp dust, and grain elevator screenings were studied.

Samples of cotton incriminated in outbreaks of illness contained no toxic gases, chemically extractable substances, insecticides, or pathogenic fungi to which the illness could be attributed. These samples, however, contained a Gram-negative, rod-shaped bacterium in numbers ranging from 3,000,000 to more than 10,000,000 per gm. It was not isolated from high-grade cotton. Seventy of 81 samples of materials reported to have caused illness contained the same strain of the bacterium as determined by biochemical tests. This bacterium is actively motile and encapsulated. Its Imvic reaction is — — + +; it ferments lactose and liquefies gelatin slowly, and it produces acid and gas in almost all differential media except adonitol, inositol, and inulin. On the basis of these biochemical findings, it has been tentatively placed in the genus *Aerobacter*.

A heat-stable, endotoxin-like substance was demonstrated in filtrates from saline extracts of stained cotton, in filtrates from broth cultures of the cotton bacterium, and in killed suspensions of the same organism. Homologous antibodies, which were capable of neutralizing or precipitating this toxic substance, were produced in rabbits through injections with these materials. It is believed that this toxic substance is in the nature of an endotoxin because of its (a) heat-stability, (b) lower antigenic capacity, and (c) increase with age of culture or destruction of cells.

The same type of disabling illness could be produced in humans by inhalation of (a) dust from normal cotton contaminated with the cotton bacterium

and its culture filtrates, (b) dust from stained cotton containing a high incidence of the cotton bacterium, and (c) a fine mist of a sterile filtrate from cultures of this microorganism. The severity of symptoms and physical findings are dependent upon the presence and concentration of the cotton bacterium or its products in the cotton dust inhaled and upon the duration of exposure.

Intradermal injections of the filtrates of stained cotton extracts and culture filtrates of the cotton bacterium in man resulted in the production of severe inflammatory lesions characteristic of an intoxication rather than a hypersensitivity.

The clinical findings developed experimentally in humans were the same as those reported in cases of acute illness among workers exposed to high concentrations of stained cotton dust. The clinical syndrome of this illness is similar to that of an acute intoxication. Since this acute illness closely resembles mill fever, Monday fever, and gin fever in cotton mill workers, heckling fever, mill fever, grain fever, and hemp fever reported in workers inhaling flax, jute, grain and hemp dust respectively, it is suggested that the toxic products liberated by the cotton bacterium or some closely related species may be the etiological agent for these diseases.

It was concluded that the acute illness occurring among workers using low-grade stained cotton is caused by the inhalation of an endotoxin-like substance produced by a Gram-negative rod-shaped bacterium contained in or on dust from stained cotton. This microorganism has been tentatively placed in the genus *Aerobacter*.

Public Health Degrees and Certificates Granted in the United States and Canada During the Academic Year 1941-1942*

THE Committee on Professional Education of the American Public Health Association presents a report of public health degrees and certificates granted in the academic year 1941-1942. With the exception of the public health nursing tables, the committee has

included only graduate students enrolled in courses leading to graduate degrees and certificates. The basis for the record is *the number of students who received degrees* rather than the number of degrees granted in the specified period.

Effect of Aluminum Hydroxide Sedimentation, Sand Filtration and Chlorination on the Virus of Poliomyelitis*

J. EMERSON KEMPF, M.D., MARTHA G. WILSON, MARJORIE E. PIERCE, AND MALCOLM H. SOULE, Sc.D., F.A.P.H.A.

Hygienic Laboratory, University of Michigan, Ann Arbor, Mich.

IT has been well established that the virus of poliomyelitis occurs in the feces of patients with this disease and of healthy contacts, and in sewage. Since the pollution of water with this virus is thus possible, and since aluminum hydroxide sedimentation, sand filtration, and chlorination are extensively used in water purification procedures, it seemed advisable to determine whether treatment by these methods inactivated or removed the virus.

ALUMINUM HYDROXIDE SEDIMENTATION AND SAND FILTRATION

In experiments on the effect of aluminum hydroxide sedimentation and sand filtration, the DG strain of virus, isolated from the stool of a poliomyelitis patient by Dr. S. D. Kramer, was used. This strain had a minimal infective dose of approximately 0.00002 gm. of monkey passage spinal cord at the beginning of these experiments, which increased in the course of this study to 0.001 gm. A sand filter for laboratory use was constructed according to a modified plan of

Baylis.^{† 1} This filter consisted of a glass tube 5' long and 2" in diameter, which was supported in a vertical position, and contained 1' of washed coarse gravel at the bottom of the tube, above which was layered 2' of Ottawa silica sand, of which 10 per cent passed a sieve of 0.508 mm. pore size and 60 per cent passed a sieve of 0.630 mm.; the uniformity coefficient (60 per cent. divided by 10 per cent) was 1.24. The 2' space above the sand was filled with water. The tube was fitted with a glass stopcock at the bottom, and a support above the filter held a bottle, from which water could be siphoned into the top of the tube. Before using, the apparatus was filled with chlorinated water and allowed to stand for at least 12 hrs. It was then drained, and back-washed with distilled water until the overflow water was clear and contained no residual chlorine.

In a preliminary experiment the filter was tested for its ability to remove *Escherichia coli* from water which had been previously treated with aluminum sulfate and allowed to settle. Three one gallon bottles were filled with water and enough of a 4 to 6 hour broth culture of *E. coli* was added to each to produce a final concentration of ap-

* This work was aided by a grant from the Clara Ward Seabury Clinic for the Study of Infantile Paralysis.

† The plan was submitted by H. A. Faber, the CMI Inc. Institute, Inc., New York, N. Y.

TABLE 1

The Effect of Aluminum Hydroxide Sedimentation and Sand Filtration on the Removal of Poliomyelitis Virus from Infected Water

Experiment No.	Aluminum Sulfate in Grains per Gallon	pH	Poliomyelitis in Monkeys Inoculated with:		
			Sedimented and Filtered Water	Supernatant of Sedimented Water	Control
1	24	7.1	1/2	0/1	1/1
2	8	7.8	0/2	0/2	1/1
3	8	7.6	1/2	1/1	1/1

proximately 50,000 organisms per ml. Eight grains of aluminum sulfate* were added to each bottle, and the contents stirred rapidly for 1 min., then slowly for 9 min. The resultant floc was allowed to settle for 3½ hrs., at which time each bottle's contents was filtered, allowing sufficient floc to enter the filtering system to form a layer over the sand 2-3 mm. thick. The rate of filtering was adjusted to 2 gal. per sq. ft. per min. in order to approximate that used in municipal water purification plants.² An agar plate culture of the effluent was made after two-thirds of the contents of the third bottle was filtered. Since this method removed 99.6 per cent of the *E. coli*, it was considered satisfactory.

The same technic was then used for testing the effect of aluminum sulfate treatment and filtration on the removal of poliomyelitis virus from river water. The pH of the water was adjusted to 7.0 to 8.0, the water autoclaved, and to each of three gallon samples was added infected monkey cord to produce a final concentration of 0.001 gm. of cord per ml. One ml. samples of the supernatant of the aluminum sulfate treated water and the filter effluent were inoculated intracranially into monkeys, and a control suspension containing 0.001 gm. of monkey cord was likewise inoculated. The monkeys were ob-

served for approximately 40 days, when they were killed, and the central nervous system examined microscopically for evidence of poliomyelitis. No monkey was considered to have poliomyelitis unless characteristic lesions were observed microscopically, even though the animal had shown suspicious neurological signs.

In Experiment 1 (Table 1), virus was not detected in the unfiltered supernatant fluid of the aluminum sulfate treated water, but was demonstrated in the filter effluent. In Experiment 2, no virus was found in either the supernatant or the effluent. In Experiment 3, virus was detected in both. It is thus apparent that virus was not consistently removed from the supernatant fluid by the settling of the aluminum hydroxide alone, nor was the virus removed in two out of three experiments by a combination of the aluminum sulfate treatment and filtration.

In the usual water purification plant procedure, no exact measurement of the concentration of aluminum hydroxide is made following the addition of sufficient aluminum sulfate to form an optimum floc. It was noted in our work that there was a marked difference in the amount of sediment formed when a selected amount of aluminum sulfate was added to a volume of water, depending on whether the sample was river water or distilled water, and also on other factors, such as pH and the rate of adding the aluminum sulfate to the water. Because of these differences

* One grain was contained in 1 ml. of a stock suspension of 17.12 grams of aluminum sulfate per liter.

the following procedure* was used to measure exactly the amount of sediment formed. A 10 ml. sample of water in which a floc had formed was placed in a Hopkins tube and centrifuged at 500 times gravity for 10 min. The volume of sediment was then measured.

In testing certain samples of artificially contaminated water, it was noted that occasionally virus was found in the resuspended sediment when none was found in the supernatant or in the control suspensions. This actual concentration by aluminum hydroxide was noted by Schaeffer and Brebner.³ In

TABLE 2

Concentration of Aluminum Hydroxide Sediment Necessary to Remove Poliomyelitis Virus from Inoculated Water

Experiment No.	pH	Aluminum Sulfate in Grains per Gallon	Concentration of Sediment in ml./liter	Poliomyelitis in Monkeys Inoculated with:	
				Supernatant of Sedimented Water	Control
4	7.3	8	0.60	2/2	0/1
	6.9	16	1.16	0/2	0/1
	6.7	32	2.20	0/2	0/1
5	7.0	8	0.40	1/2	2/2
	6.9	16	1.03	1/2	2/2
	6.7	32	1.50	0/2	2/2

The concentration of precipitate present when virus was removed from artificially contaminated water was next determined. It was found in Experiments 4 and 5 (Table 2) that virus was not removed from the water when the amount of aluminum sulfate added resulted in a volume of 0.60 or 1.03 ml. of sediment per liter. Volumes of 1.16 and 1.50 ml. per l. were adequate to produce non-infective inoculums. These amounts of precipitate were compared with the amounts in samples of water obtained from the flocculating basins of four water purification plants in Southern Michigan. In each of three of these samples (Table 3), the concentration was less than 1.16 ml. per l., which was the quantity required to remove the virus from artificially infected water. In the water from one plant, 8 ml. per l. was found, which according to these experiments was more than adequate to sediment the virus.

our experiments, aluminum hydroxide sediments were produced in samples of

TABLE 3

Concentration of Aluminum Hydroxide Sediment Found in Samples of Water from Purification Plants

Plant Number	pH	Concentration of Coagulant Added in p.p.m.	Concentration of Sediment in ml./liter

water to which virus had been added, and monkeys were inoculated with suspensions of the resuspended sediment as well as with the supernatant fluid. Monkeys were also injected with samples of the inoculated water to which no aluminum sulfate had been added. Only monkeys inoculated with the resuspended sediment from the water containing 0.56 ml. per l. developed poliomyelitis, as evidenced by paralysis and histological examination of the spinal cords (Table 4, Experiments 6 and 7).

* This method was suggested by Dr. W. J. Nungesser, University of Michigan Hygienic Laboratory.

TABLE 4

Concentration of Poliomyelitis Virus by Means of Aluminum Hydroxide Sedimentation

THE EFFECT OF CHLORINATION ON THE POLIOMYELITIS VIRUS

In a previous publication⁴ it was demonstrated that 1.50 p.p.m. of chlorine in the form of chloramine inactivated in 20 min. a suspension of spinal cord infected with MV virus, but that 0.86 and 1.00 p.p.m. for 20 min. failed to inactivate. The virus remained viable after exposure for 1 hr. to 0.90 p.p.m., and even after 4 hrs. exposure to a chlorine concentration of 0.2 p.p.m. These studies were continued to determine the concentration of chlorine required to inactivate 2 strains of virus in the time of chlorine exposure used in the average chlorination plant.

In further experiments on the effect of chlorination the MV and DG strains were used, with minimal infective doses of approximately 0.001 and 0.0001 gm., respectively, of infected spinal cord. Because of expense, and the unreliability of tests in monkeys of the minimum dose to produce paralysis, these doses were not accurately determined.

In Experiment 8 (Table 5) river water was used, and the source of chlorine was sodium or calcium hypochlorite. The chlorine content of the water was determined by the orthotolidine and starch-iodide methods. Approximately 0.70 ml. of a 1:10 suspension of spinal cord infected with the MV strain was added to each of several 100 ml. samples of water and various amounts of chlorine were then added. These were allowed to stand for 20–25 min., at which time chlorine

determinations were made and 1.00 ml. of each specimen was inoculated intracranially into a monkey. Failure of the chlorine to inactivate the virus was evidenced by the subsequent development of paralysis in the monkeys with histopathology compatible with that of acute poliomyelitis. Inactivation of the virus was determined by absence of paralysis or tremors in the surviving animals, which were exercised daily during the 40 day period of observation. One and five-tenths p.p.m. of chlorine inactivated the virus and 1.00 p.p.m. was the maximum concentration tested which failed to inactivate the virus.

TABLE 5

Effect of 25 Minutes Exposure to Chlorine on MV Virus

Chlorine in p.p.m.		pH	Effect on Virus
O-tol *	SI †		
0.20	0.70	7.0	Not inactivated
0.60	0.40	7.3	" "
0.85	8.2	" "
1.00	8.3	" "
0.55	1.50	7.0	Inactivated
1.50	8.2	Inactivated

* Chlorine content determined by orthotolidine method.

† Chlorine content determined by starch-iodide method.

In Experiment 9 (Table 6) tap water was used and the effect of chlorine gas dissolved in water on the DG strain of virus was tested. The chlorine content of the water was determined by the starch-iodide test only, because of color interference encountered in the orthotolidine reaction. The rest of the technic was that of Experiment 8. It was found that the amounts of chlorine

required to inactivate the DG strain did not differ markedly from that required to inactivate the MV strain. One p.p.m. inactivated the virus, while 0.90 p.p.m. just failed to inactivate.

TABLE 6

*Effect of 25 Minutes Exposure to Chlorine
on DG Virus*

1.90	8.0	"

* Chlorine content determined by starch-iodide method.

SUMMARY

Experiments on the effect of aluminum hydroxide sedimentation and sand filtration, and further studies of chlorination on the poliomyelitis virus are described. The virus was not removed from water by aluminum hydroxide sedimentation and filtration methods which removed 99.6 per cent of *E. coli*. Virus was removed from an

artificially inoculated water by producing an aluminum hydroxide sediment of 1.50 ml. per l. The virus was not inactivated by this procedure, however, but remained in an increased concentration in the sediment. Samples from three of four water purification plants selected at random did not contain a sufficiently high concentration of aluminum hydroxide to sediment the poliomyelitis virus.

The concentration of chlorine which inactivated the MV strain was 1.50 p.p.m. for 25 min.; while the DG strain was inactivated by 1.00 p.p.m. but not by 0.90 p.p.m. for 25 min. These concentrations of chlorine are in excess of those recommended for the production of bacteriologically safe drinking or swimming pool water.

Surveys of the Nutrition of Populations*

Description of the Population, General Methods and Procedures,
and the Findings in Respect to the Energy Principle (Calories)
in a Rural Population in Middle Tennessee

JOHN B. YOUMANS, E. WHITE PATTON, AND RUTH KERN

*Department of Medicine and the Department of Biochemistry, Vanderbilt
University, Nashville, Tenn.*

THE growing appreciation of the importance of nutrition and the realization that mild nutritional deficiency states are frequent in the general population have made nutrition an important concern to public health services. At the same time the development of improved procedures for the detection of nutritional deficiencies in their earlier and milder forms, before the development of obvious lesions, has suggested that methods might be developed for use by public health agencies to detect these deficiencies and make surveys of nutrition of populations as in the epidemiological investigation of other diseases. Such studies would, of course, provide the information and background necessary for the prevention and cure of such important disorders. With this thought in mind we have made a survey of the nutrition of a population with the purpose of developing methods suitable for public health use, demonstrating their effectiveness and securing information as to the nutrition of the group selected.

Surveys of nutrition are of various kinds and can be made in different ways depending on the purpose of the survey

and the available facilities. At present the term is usually considered to mean a study which includes both a record of food consumption and an assessment of the state of nutrition of the individual subjects.

Studies of food consumption have long been used as a method of measuring the nutrition of populations. Such studies have yielded very valuable information but the method is indirect and relatively inaccurate. It determines the state of nutrition by an inference; the subject is found to eat so much of this and that food containing certain amounts of the different nutritive factors, therefore his nutritive state is judged to be thus and so. At the present time this method is insufficient by itself. It was used in the past mainly because satisfactory methods for assessing the state of nutrition by physical examination or laboratory tests were lacking. Such methods have however been devised and improved so that now they offer the possibility of determining the actual state of nutrition by direct and objective methods. The study of food consumption, however, remains an important part of a survey of nutrition because of its function in determining the etiology and epidemiology of dietary deficiencies. Furthermore, for the present it offers a check and control of other methods of assessing nutrition, an im-

* The studies referred to herein were conducted under the auspices of the International Health Division of the Rockefeller Foundation of New York City by the Nutrition Unit of the Departments of Medicine and Biochemistry of the Vanderbilt University School of Medicine, Nashville, Tenn.

portant function in the period of trial of new, direct, and objective tests. For these reasons a complete survey of nutrition, one that includes both a study of diets and an assessment by examination and laboratory tests, is desirable. The scope and thoroughness of these two procedures will vary with the needs and purpose of the survey and the facilities that are available for it.

For our purposes the complete survey was employed. The area selected was a portion of Wilson County, Tenn., about 15 miles from Nashville. It was chosen as a representative area* of Middle Tennessee, predominately rural, but containing a village community with a limited number of tradesmen, professional people, and skilled workers. A number of the inhabitants worked at a nearby rayon plant, driving to and from their work.

Topographically, the country is rolling and borders on the Cumberland River. The soil is predominately a clay of limestone origin, rather shallow but much of it good. Areas of poorer soil and, in particular, rocky cedar glades are interspersed among areas of the better soil. The type of agriculture is general, diversified farming. County and home demonstration agents and similar organizations are present.

Among the reasons for the selection of the area aside from its suitability as a representative area were its distance from Nashville which facilitated the work of the survey, the existence of an active full-time county health service, and a community spirit which promised a satisfactory coöperation in the study.

If it be objected that this in itself may

have affected the representative average character of the area it may be said that such a spirit was by no means unanimous and that the existence of a considerable amount of civic interest and activity together with a significant lack of it in some groups are characteristic of the region.

Considerable effort was made to explain the proposed survey to the people and secure their coöperation. Visits were made to meetings of civic clubs, women's clubs, parent-teacher associations, the Grange, the schools, and similar organizations. Key persons in the community, teachers, leading farmers, civic leaders, and others were called upon, the procedure was explained, and their coöperation and help were solicited. Help was obtained from the county health officer who offered his assistance and that of his staff in sponsoring and explaining the procedure, and provided an introduction to many elements of the community. In particular, each doctor in the vicinity was visited, not only those actually living in the area but also those who might have patients in the area. All participation by the subjects was voluntary and unremunerated. It may be of interest that it was solicited on the basis of a contribution to public health, to science, and to humanity generally rather than of benefits that might be received by the subjects.

The actual survey consisted of a record and study of food consumption on both a household and individual basis, a medical history, physical examination, and various laboratory tests. Only part of the details of these procedures will be presented here; complete details for each of the nutritive factors investigated will be given with the reports of the study of each of those factors. The present report deals with the characteristics of the area and the population, the general procedures employed, and the state of nutrition in respect to the energy factor (calories).

* The area originally selected was larger and contained about 2,500 inhabitants. It was thought that only about 60 per cent of the inhabitants would coöperate in the study, giving some 1,200 subjects, the number desired. Preliminary experience, however, indicated that about 90 per cent would coöperate, and consequently the size of the area was reduced to that shown, with a population of about 1,300.

GENERAL PROCEDURES

The study and record of the food consumption were made by and under the direction of one of us (R.K.). The general procedure followed is described below and will apply to subsequent reports, but the variations, special procedures, and methods used for the study of each of the particular dietary factors except calories will be described in the respective reports.

After preliminary visits to secure cooperation, to explain the procedures, and to make necessary arrangements, a group of households* was selected containing such number of individuals and located so that it could be managed by a single field worker with time for one visit daily to each family during the period of study.

The day before starting the record of food consumption the household was again visited and a roster was prepared, each individual receiving a household number and an individual number. Date of birth, length of time in the household, and occupation of each were obtained and the earnings of each and of the household as a whole were ascertained and recorded. The member or members of the family who were to keep the records were instructed in the procedure and the forms to be used. They were told that the investigators would return the next morning to help them with details of weighing and measuring, and not much stress was laid on these matters at this visit. The responsible member or members of the household were instructed in the recording of food purchased, produced at home, and received as gifts. In some instances the household inventory of food was made at this time. In other cases this was done the following day. Every effort was made to prevent any changes in the food

habits, and the subjects were informed that a second examination would be made in the following fall or spring.

Some time after the food consumption was studied and recorded, within two weeks in the majority of cases, the medical history was obtained and the physical examination and laboratory tests were made.† For this purpose the subjects were visited in their homes or were brought to the schools of the district or to Vanderbilt Hospital. When examined away from home appointments were made by the field workers, usually at their last visit, and transportation was arranged. For the most part the attendance for examination was easily managed at the first trial but because of conflict with their occupations, particularly with farmers, it was sometimes necessary to arrange more than one appointment and with a small percentage of "stragglers" several attempts were necessary before the examination was completed.

Because it was necessary for the adaptometer (photometer) test, and preferable for the x-ray studies that the patients come to the hospital, many of the subjects, particularly the adults, were examined there. However, examining rooms and facilities for obtaining blood and other material for laboratory tests were set up at the consolidated school which accommodated all the white children in the area. Many of the white children were examined and had specimens obtained there. Similar arrangements were made at the smaller schools for Negroes. Such subjects came to the hospital for the x-rays and adaptometer tests at a later time.

METHODS

On the first day of the record period (7 days), the field worker called and the record as prepared to that point was

* Household is used in place of family because the unit of study included not only members of a family but all others for whom it was the principal source of meals.

† In a few instances the examination and laboratory tests were made first and the diet record obtained afterward.

reviewed. Measurement was stressed and the use of cups and spoons as well as the classification of fruits and vegetables into large, medium, and small, or by diameter or length, was made clear, often with a practical demonstration. Recipes for mixed dishes, the methods of recording amounts of various ingredients and the type of cooking used for various foods and dishes were discussed. Additional information and instructions were given and any mistakes corrected. Similar visits were made on the succeeding days of the period and sometimes several daily visits were made. If necessary the investigator went to the home at each meal and recorded the food eaten but this was rarely necessary. At the last visit appointments were made for the medical examination, instructions were given for the collection of urine specimens and similar procedures, and transportation arranged.

For the household inventory and purchase record all the food in the house was weighed, measured, and counted at the start of the seven day period, by a member of the family and the field worker. Weights of loose food were checked and packaged food inspected for net weight and losses. Because most of the subjects were farmers there were often large amounts of potential food available—eggs, hams, truck gardens, etc., but this was not included unless it was present and available at the start of the recording period for early consumption. Forms were provided on which food purchased, received as gifts, or produced at home (garden truck, eggs, milk, etc.) were recorded. At the end of the period another similar inventory was made.

For determining the food consumption of the individual the food actually eaten each day was recorded either by the individual himself or by some member of the household for three days during the week. For many of the sub-

jects these were non-consecutive days and every effort was made to avoid periods containing unusual days. Food eaten away from home and quasi-food such as candy, soft drinks, and alcoholic beverages were included. The intake of breast milk was noted but the milk was not analyzed nor the amount measured.

The quantity of food was measured as it was eaten from the plate either cooked or as otherwise prepared for eating. Measurement was by household measures using standard cups for such foods as cereals, various vegetables, soups, milk, etc. Smaller amounts were measured by the tablespoon and teaspoon with level measure. Volume and weight of such common household measures were checked by actual testing. The amount of such foods as breads, cake, meat, biscuits, etc., was determined by three dimension measurements and reference to a prepared table for the weight of various sized portions. Fruits and vegetables commonly eaten in the whole state, cooked or raw, such as bananas, whole potatoes, apples, and the like were designated as large, small, or medium according to standard practice with the food tables employed. Kitchen waste (except losses in cooking) was not a factor and table waste was controlled closely by recording only food eaten in so far as possible. The general table waste was a minor feature in this study.

Individual recipes were obtained for nearly every composite dish. For example, more than twenty recipes for pies were used in the calculation of dietary intake and four or five recipes for slaw. Proper allowances for changes in weight and volume caused by heat, dilution with water, and other procedures of preparation and cooking were made according to the type of cooking used, following standard practices.

For the calculation of the dietary intake various standard tables of food values were used as far as possible. The

tables used were as follows: For calories, carbohydrate, protein, fat, included in the present report, Tables XIV, XVIII, and XIX of *A Laboratory Handbook for Dietetics*, by Mary Davies (Swartz) Rose,¹ supplemented when necessary by values from *The Fundamentals of Nutrition*, by Hawley and Maurer-Mast,² the *Farmers' Bulletin*, "Rabbit Raising," U. S. Department of Agriculture,³ and *The Structure and Composition of Foods*, by Winton and Winton.⁴ Details of the sources of food values for other specific nutrients will be given with the respective reports on those factors. Analyses by the respective companies or general commercial recipes were used for commercial candy bars, cakes, cookies, and similar foodstuffs. Finally, in a few instances, when reported analyses were not available, values were assigned arbitrarily on the basis of general knowledge, similarity to other food, etc. All of these values were combined into "working tables"* where the various sources are indicated and where household measures are reduced to standard weights and sizes. Here also are the various recipes, notes, and similar data.

When necessary, adjustments were made for the seasons according to the tables. Vitamin values refer to raw weight corrected for vitamin losses in cooking and the weights of vegetables refer to cooked or raw weight depending on the form in which they were eaten.

Both history and physical examination were done by physicians with special training in nutrition, and, for children under 4 years, were done by a pediatrician. Special attention, naturally, was paid to the symptoms and signs of nutritional deficiencies, particularly to those of the early or mild deficiencies and to diet and habits of eating.

Definitions and descriptions of the details of the history and physical examination in respect to the individual nutritive factors will be given with the reports dealing with each factor. The present report deals with the energy principle (calories) and the features noted in the history and examination with respect to energy nutrition were as follows: In the *history*, a past tendency to overweight or underweight, a history of recent abnormal increases or decreases in weight, the number of meals eaten daily, the consumption of alcoholic beverages, and the general characteristic of the diet. In the *physical examination*, the state of subcutaneous tissue and musculature and, classed with either the physical examination or the *laboratory*, the height and weight.

The history of past obesity or leanness, recent changes in weight, and habits regarding meals and eating was obtained by the clinician at the time of the examination and the findings in these respects are an evaluation by him of the responses of the subject to his inquiry. The state of the musculature and subcutaneous tissue represents also the examiner's judgment and was based only on a rough quantitative or attempted quantitative measurement by simple inspection and palpation. It was felt, that in view of the unsuitability and unreliability of the objective quantitative measurements which have so far been devised for this purpose, equally satisfactory results would be obtained by taking the examiner's opinion to be based on a number of related observations, such as elasticity of the skin, constitutional type, age of the subject, etc.

Weight was measured on standard platform scales, without coat or shoes and recorded to the nearest quarter pound except for children under one year old. The latter subjects were weighed on a balance scale to the nearest quarter pound. The standards for

* Copies of these tables are much too lengthy for publication with these reports. They can be furnished by special arrangement by writing to the authors, as may copies of record forms used.

weight used were those which allow for weight of clothes and although there was some variation with season this was not great.

Height was measured with a steel measuring rod attached to the scale, with the subject bareheaded, standing to attention and in stocking feet. It was recorded to the nearest quarter inch. Length rather than height was measured in young children. For standards of weight according to height, age and sex, the tables of Baldwin and Wood⁵ have been used.

The method of obtaining the socioeconomic data and the classifications and definitions used in this part of the study require little comment. Dependent members of the household have been assigned to the income group of the household as have independent members. The latter had their own income determined separately, but in determining household income it has been included in the household income because it is the latter which determines the character of the dietary. It was considered that income of the individual member, if used in part to pay for board in the family merely served to increase the income level of the family unit as related to food supply. Income has been calculated to include only actual cash income. Additional income in the form of food has been considered separately under the heading of home food supply.

Relief status was ascertained by direct inquiry and by reference to official rolls if necessary. The number on relief was very small and included mainly those receiving old age pensions. When relief was given the amount, in cash or in kind, was indicated.

For the purpose of analysis the data obtained were coded and transferred to punch cards. In future studies the use of the code or a similar one will make it possible to analyze the data and secure the results of a survey in a very short time after the data have been collected.

RESULTS *

The inhabitants of the area at the beginning of the study numbered 1,272 individuals, included in 311 households. Of these, 26 households with 86 individuals refused entirely to cooperate in the study, leaving 1,186 individuals in 286 households who began the study. Of this number 34 individuals subsequently failed to complete their diet study, either because they refused to continue further, because they moved away, or were too ill to continue. Thus of a total of 1,272 inhabitants 1,152, or 91 per cent, completed the dietary part of the first period of the survey. At the first examination 58 individuals (50 white and 8 colored) failed to be examined and have the laboratory tests, for reasons listed above, leaving 1,094, or 85 per cent, of the total population who completed the study in the first period.[†] In addition 5 subjects were examined who did not complete the individual dietary study.

Over 90 per cent of the subjects had their *first* examination in the late summer and the fall, the remainder in the late winter and spring.

The distribution of the subjects according to age,[‡] sex, and race is shown in Table 1. The proportion of Negroes to whites is slightly higher than the average for the region which is approximately 25 per cent.

The distribution of white and colored households according to annual cash income is shown in Table 2. Among the whites there is a fairly equal distribution among the various income levels but among the Negroes few had an an-

* The results of the first examination only are given here. Comparison of the results of the summer-fall and winter-spring examinations will be reported later.

† This total number does not apply to all the items of the examination. In some cases, as with young children, certain examinations were of necessity omitted and occasionally a determination or a part of the examination was missed.

‡ Determined to the nearest birthday except for those one year old and under whose age is determined to the nearest month.

nual income over \$1,000. Over half had an income less than \$500. Only 6 colored households, composed of 26 individuals, and 1 white household of 2 persons, were "on relief." In 5 of the colored households the relief consisted of an old age pension, \$2 to \$10 per month. Its nature in the 6th is unknown. For the single white household direct relief was received in the form of \$2 weekly for groceries.

The "size" of the households, which may be an important factor in the nutrition of the members is shown in Table 2-a. Little difference is found between white and colored, though the latter households were slightly larger on the average.

The status of the households with regard to home food supply is shown in Table 3. Slight amount means a poor, seasonal garden, with or without a few chickens but no hogs, cows, or other livestock. Moderate amount includes one cow per household and a garden estimated to furnish about half a reasonable supply of vegetables. Large amount is anything over the latter. There is noted a tendency for the home food supply to increase with the increasing cash income, those with the highest cash income tending to have the best home food supply. Those most in need seem to have had the least. This tendency

was nearly lacking in the Negroes, perhaps because of the concentration of households in the two lowest income groups.

The status with respect to occupation is given in Table 4. Totals do not correspond to the total number of subjects because some have been listed under more than one occupation. School children form the largest group in both white and colored, with housewife and agricultural worker next in each group respectively. Percentages are very much the same in white and colored. However, in the other classifications a considerable difference between white and

colored is found, with relatively much smaller numbers of colored in manufacturing, professional, and tradesman classifications and more in the varied occupations classified as "other," house servants for example. There is slightly greater percentage of colored with "no occupation." The larger percentage of preschool children among the Negroes probably reflects the later age of starting school.

The educational status of the subjects is given in Table 5. The table is somewhat obscure because there is no clear indication in the table whether schooling is continuing or not, and in certain age groups the education stated may not be the final amount expected. A finding of interest is that among the Negroes the accomplishment, in the sense of attendance, up through the 6th-8th grade is

the same as for the whites. In fact, the percentage is somewhat greater, 40 and 36 per cent. The break at this point coincides with the lack of facilities beyond this educational level. The nearest high school for Negroes was at Nashville, about 15 miles away. Thus, as far as the opportunity was available, the education of the Negroes seems equal to that of the whites in grades attended.

NOTE: The second section of this paper will appear in this *Journal* at an early date.

Effect of Prolonged Storage on the Antigenicity of Chloroform-Inactivated Canine Rabies Vaccine*

CHARLES N. LEACH, M.D., F.A.P.H.A., AND
HARALD N. JOHNSON, M.D.

State Board of Health, Montgomery, Ala.

IN the course of previous tests of the antigenicity of chloroform-inactivated canine rabies vaccine it was clearly demonstrated that a single 5 ml. dose, administered subcutaneously, afforded dogs a high degree of resistance to experimental intramuscular inoculation of rabies street virus.¹

Having thus obtained evidence that dogs can be immunized with rabies vaccine containing no demonstrable virus it was considered important to determine the effect of prolonged storage at refrigerator temperature (5° C.) on the antigenicity of this product. A large volume of one lot of chloroform-inactivated vaccine was obtained from a commercial source and stored at this laboratory. This was first tested in dogs 4.5 months from the date the vaccine was prepared. The same vaccine was again tested after 6 and 12 months' further storage.

MATERIALS AND METHODS

The dogs used in the three experiments had not been previously vaccinated and were purchased directly from the owners. In each of the three tests the dogs were so allotted that the average age and weight of the vacci-

nated and control groups were, as near as possible, the same. The majority of the dogs were between 1 and 2 years of age. In order to satisfy statistical requirements, at least 30 dogs were included in each vaccinated and control group.

The chloroform-inactivated vaccine was of ovine origin and contained 33 1/3 per cent of brain material. The vaccine was produced November 13, 1940. The safety test was completed at the commercial laboratory January 27, 1941, and no live virus was demonstrated. Further tests at this laboratory likewise proved negative. The first group of dogs was vaccinated March 31, 1941, the second group, October 1, 1941, and the last group April 3, 1942. All vaccinated dogs were given a single 5 ml. dose, 2.5 ml. being injected subcutaneously on either side of the cervical spine.

The vaccinated dogs were inoculated with rabies virus 30 days after vaccination in parallel with like groups of control animals. The test virus was obtained from the brains of dogs dying of rabies after natural exposure. This brain material had been stored in pure glycerin in an ice cream hardening cabinet at, -25° C. At the time of each challenge virus test an entire brain was weighed and after thorough trituration was diluted 1:10 by weight in dis-

* The studies and observations herein reported were conducted with the support and under the auspices of the International Health Division of The Rockefeller Foundation and the Alabama State Board of Health.

tilled water. The supernatant fluid after centrifugation was used as the street virus inoculum.

An injection of 0.5 ml. of the virus suspension was given into each masseter muscle of all vaccinated and control dogs. The animals were subsequently observed for a period of at least 90 days. Autopsies were performed on all dogs dying during the 90 day observation period. The brains were examined for Negri bodies and if this examination was negative, 0.03 ml. of a 10 per cent suspension of a pool of various portions of the brain was inoculated intracerebrally into each of four white mice.

EXPERIMENTAL RESULTS

The results of the three tests of the antigenicity of one lot of chloroform-inactivated rabies vaccine are set forth in Table 1. In test number one, 2 vaccinated dogs died of causes other than rabies during the 90 day period of observation. There were no incidental deaths in the control group. Two of the remaining 32 vaccinated dogs died of rabies (6 per cent), while 20 of the 36 control dogs died of the disease (56 per cent).

and 1 control dog died of incidental disease during the experiment. Six of the 40 remaining vaccinated dogs died of rabies (15 per cent) compared with 25 rabies deaths in the group of 39 control dogs (64 per cent).

DISCUSSION

It is evident from the results obtained in the three tests that in each instance a high degree of protection was afforded the vaccinated dogs by a single injection of vaccine. In view of the inability to demonstrate live virus in the chloroformized vaccine by animal inoculation it is unlikely that the persistent antigenicity of this product can be explained by the presence of minimal amounts of live virus.

Although there is suggestive evidence that the antigenicity of the product was slightly reduced by prolonged storage, the difference in the results obtained in the first and third tests could be explained by chance alone. The lower mortality among vaccinated dogs in test one as compared with test three was accompanied by a proportional difference in the mortality of the two control groups. A statistical study of the

TABLE 1

Three Tests of the Antigenicity of One Lot of Commercial Chloroform-Inactivated Canine Rabies Vaccine

Test	Age of Vaccine	Vaccinated Dogs			Control Dogs			* Statistical Significance
		Number of Dogs	Died of Rabies	Per cent Dead of Rabies	Number of Dogs	Died of Rabies	Per cent Dead of Rabies	
I	4.5 months	32	2	6	36	20	56	0.0000
II	10.5 months	33	4	11	41	27	66	0.0000
III	16.5 months	40	6	15	39	25	64	0.0000

* By corrected χ^2 test. Likelihood of getting a difference as great or greater than that observed in the mortality of the vaccinated and the control groups by chance alone.

In test number two, 2 vaccinated dogs and 1 control dog died of causes other than rabies during the 90 day observation period. Four of the 38 remaining vaccinated dogs died of rabies (11 per cent) while 27 of 41 control dogs succumbed to the disease (66 per cent).

In test number three, 1 vaccinated

three tests shows that in each instance the difference in the mortality of vaccinated and control dogs was highly significant.

The present regulations governing the marketing of canine rabies vaccine require that the date of preparation of the vaccine be noted on the product and

that the expiration date be given as one year from the date of preparation. It is evident from the results obtained in this study that the antigenicity of chloroform-treated rabies vaccine, if stored at refrigerator temperature, is well maintained for one year after production.

SUMMARY

A single lot number of commercial chloroform-inactivated canine rabies vaccine was tested in dogs 4.5, 10.5, and 16.5 months after preparation. In each test the vaccinated dogs were given a single 5 ml. subcutaneous dose of vaccine. The vaccinated dogs were inocu-

lated intramuscularly with rabies street virus one month after the day of vaccination in parallel with like groups of control dogs. At least 30 vaccinated and 30 control dogs were used in each test. In each test the vaccinated dogs developed a highly significant degree of resistance to experimental inoculation.

NOTE: The statistical analysis of the experimental results was made by Leonard V. Phelps of the Department of Vital Statistics, Alabama State Board of Health.

Highlights of the 71st Annual Meeting

A STENOGRAPHIC report, with very little editing, is presented herewith of the Fifth General Session of the St. Louis Annual Meeting of the American Public Health Association held in the Convention Auditorium, November 30, 1942, as the final session in the meeting. This was an informal panel discussion under the auspices of the Editorial Staff of the AMERICAN JOURNAL OF PUBLIC HEALTH. Participants included Harry S. Mustard, M.D., JOURNAL Editor, Director of the DeLamar Institute of Public Health, Columbia University, New York; Leona Baumgartner, M.D., Director of the Bureau of Child Hygiene, New York City Department of Health; Martin Frobisher, Jr., D.Sc., of the School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.; Roy J. Morton, C.E., Vanderbilt University School of Medicine, Nashville, Tenn. (substituting for Arthur P. Miller, C.E., U. S. Public Health Service, New York, N. Y.); and James E. Perkins, M.D., Director, Division of Communicable Diseases, New York State Department of Health, Albany. The presiding officer was Reginald M. Atwater, M.D., Managing Editor, AMERICAN JOURNAL OF PUBLIC HEALTH, and Executive Secretary, American Public Health Association, New York.

THE CHAIRMAN: It is only natural that the emphasis so far in these meetings has been on the individual scientific sessions and on the specialties we have, as distinguished from those things which we have in common as public health workers. Here today we are bringing you an over-all view which we hope will give you some orientation on our common interests in public health. It has been thought well that the Annual Meeting should end on this comprehensive note.

It is also intended that you should see something of the way in which the editorial staff of the AMERICAN JOURNAL OF PUBLIC HEALTH approaches the matter of selecting the content of the twelve issues of the JOURNAL. We hope that the participants will hereafter be more to you than names on the JOURNAL masthead.

Let me say at the outset that it is not intended for this session to be entirely inclusive of all the highlights of the Annual Meeting. The content of the last seven days has been far too inclusive for that to be possible. Never-

theless, we shall try to make the best use of this opportunity to interpret some of the scientific sessions to those who could not attend because of other preoccupations.

The Association itself has taken some important actions in St. Louis. Steps are under way to create a new section on school health and a committee has been authorized to be charged with the job of implementing action in the whole area of school health policies and projects. Action was also taken this year to establish provisionally a section on dental health. By the time of the next Annual Meeting it seems likely that both of these sections will be ready for formal establishment, thus raising the number of sections from ten to twelve.

But now for the highlights of the program itself. Dr. Mustard, will you comment on the broad significance in Dr. Parran's address at the First General Session on Dynamic Public Health in Global War?

DR. MUSTARD: There were two things that I brought away with me from Dr. Parran's discussion which related to a

trip he recently took into Mexico and South America. One of the things which he emphasized is that South and Central America and Mexico have something to teach us. We have gone hitherto upon the more or less comfortable and perhaps not entirely justifiable assumption that the flow of knowledge and the flow of health must all be from North America southward.

I had the opportunity sometime ago to visit the Caribbean and the Central America areas as well as the northern part of South America. I was amazed there at the enthusiasm, the vigor, the ingenuity with which these people have attacked their problems. They have developed devices and procedures in malaria control, for instance, for which they need apologize to no section in the world for thoroughness of coverage and for basic scientific approach to the problem.

One other point that I should like to emphasize from Dr. Parran's talk—and this is one of which we are all more or less conscious—is that the interchange of people and goods and opinion from now on with these countries is going to be multiplied a hundredfold. When we think of the length of time that it once took, for instance, to get into some of the portions of South America as compared with the comparatively short airplane flights today, I think we can understand that there is going to be an intercontinental life and concern between the two continents that we have never approached before.

CHAIRMAN: Dr. Baumgartner, you attended the wind-up session of the Health Education Institute. Will you give us the highlights of that final session?

DR. BAUMGARTNER: I think I might say that it warmed all the cockles of an editorial heart to hear the final wind-up speech by Dr. Winslow, because it was put in those golden words in which Dr. Winslow can so well sum-

marize a session. He summarized two full days which included the most active audience participation there has been in any Health Institute program, and he summarized those days which had been spent in talking about community organization by drawing an analogy with a political election. He said that, as far as he could discover, a political election was not won by the parades and the posters, but it was won by the ward heeler and the ward boss who went around and got the votes, and that community organization and health education were not accomplished by posters and handbills, but were achieved by sound community organization.

He made the point that the job ahead of us is going to be a more difficult one than the job behind us, because the old motivations of fear of the spread of contagious diseases, for example, were gone, and that in the job ahead of us in making a democracy work, there was going to be a great difference as to whether or not we *educate* the people or whether we *train* them. He pointed out that probably both education and training were necessary. He pointed out that you could *train* a plant, but you had to *educate* a man. In training people, you could teach them automatically to respond to external stimuli; but if you wanted imagination and creative leadership, you really had to *educate* people. I am sure we will all want to study more carefully that differentiation between education and training, which Dr. Winslow made.

CHAIRMAN: Mr. Morton, will you give us a little insight into the sessions of the Conference of State Sanitary Engineers?

MR. MORTON: As you know, the Conference of State Sanitary Engineers is an advance meeting, but it is traditional that that organization meet with the American Public Health Association. For a good many years the Conference of State Sanitary Engineers has had, as

full members of the Conference, only the chief engineers of the several states and territories and representatives of the U. S. Public Health Service. This time, the meetings were attended by more than a score of sanitary engineering representatives from the Central and South American countries. They were asked and urged to participate and did participate, apparently enjoyably and apparently with mutual profit.

The most significant result was that action was begun by which each of the Central and South American countries will be invited to have a full member of the Conference of Sanitary Engineers, thus furthering in a significant way our hemisphere solidarity.

CHAIRMAN: Dr. Mustard, do you think we can use in the JOURNAL that very generous resolution that the South Americans presented last evening at the banquet session?

DR. MUSTARD: I think that it would be unwise to make a point-blank answer at this time. However, that gives me an opportunity to say something that I have long wanted to say: The material as published in the JOURNAL is not always chosen on the basis of its absolute worth, but rather largely on the basis of its relative worth.

We turn down about two and a half papers for every one that we accept. Consequently, the question of whether or not we could find a place for those resolutions in the JOURNAL would to some extent be a matter of space. However, other factors would influence it, in that we do believe that one of our great opportunities, as I have just said, is that of developing better relationships with South and Central America.

These Latin Americans are, incidentally, the most courteous people in the world, and things that we may sometimes overlook or perhaps not pay a great deal of attention to, are matters of considerable importance to them.

And so I should think we ought to give very careful consideration to the publication of these resolutions.

I should like to say one thing more about the JOURNAL, I am very anxious to get papers, to have papers come in from some of the younger people in the Association. There are certain names, including my own, that I have seen so often in print that I am weary of them, and I should like to see some new blood come pumping and pulsing through in terms of papers. Now, I am not going to promise you that just because you are young, you are going to have your paper accepted, but I can promise you that merely because you are not in the "stuffed shirt" group, there is no reason why your papers will be turned down, and I should welcome contributions from some of the younger members of the Association.

CHAIRMAN: Dr. Perkins, some of us did not get around to all of the meetings that we wanted most to attend; and I must confess that one of the papers that I was particularly interested to hear was that by Dr. Robertson of Chicago on germicidal vapors as a means of disinfecting air. Please give us a summary of what he said.

DR. PERKINS: Dr. Robertson reported further on his experiments with propylene glycol. For those of you who are not familiar with his previous experiments, this hygroscopic material, when sprayed into the air, has the capacity to kill microorganisms in the air; so you can see its possibilities in the future control of air-borne infection. As the effect is instantaneous, it seems clear that this aerosol performs its work in the vapor stage rather than in the droplet form.

The most interesting aspect of Dr. Robertson's paper at this meeting, to me at any rate, was a further report on his studies of toxicity. The question which immediately comes to mind is

what is the effect of these vapors on man? Propylene glycol has been given orally and intravenously to human beings without toxic reactions. Nevertheless, Dr. Robertson has hesitated to subject human beings to breathing the gas until it has been adequately tried on animals. He has some rats which have now been subjected continuously to this vapor for fifteen months without any apparent ill effect. He has also tried it on monkeys, a step closer to the human being, and they have been subjected to this vapor continuously for a period of four months; also apparently without any ill effect.

CHAIRMAN: Dr. E. R. A. Merewether of the British Ministry of Labor is here—Dr. Merewether, does that relate to anything that has been done in England in connection with attempts to control respiratory infections?

DR. MEREWETHER: Yes, it does. As you may know, the Medical Research Council has experimented with various solutions for disease-infected atmospheres, mainly in connection, of course, with shelters during the blitz winter, and the one they have been using mostly has been an ordinary hypochlorite solution. That, of course, is not suitable for a room like this one, because, as you will agree, it would bleach the curtains, for instance, but it is very suitable and cheap for vast numbers of shelters which have been occupied during the night and require disinfecting before being occupied again the following night.

With regard to factories, various experiments have been made using cheap oil on the floors, and these have been found to reduce the percentage of hemolytic streptococci and organisms of that class.

I would say that we in England have not progressed very far, and I am deeply interested in this paper, which unfortunately I could not hear because it was out of my session, and I am hoping to be able to read it in the published

proceedings. There is no doubt that as the war progresses and transfer of populations takes place, even on the small scale that has happened in my country, this question of the transfer of respiratory infections is of supreme importance. In that connection, we have had an increase of cerebrospinal meningitis in my country, and we also have thought of separating people in canteens, in factories, etc., by cellulose acetate screens and the like. But, as I say, we have not progressed very much further than thinking and experimentation, except with the disinfection of shelters.

CHAIRMAN: One of the features of this meeting has been the accessibility of Dr. Merewether, Dr. William Frazer, of Liverpool, and Sir John Orr, who have added much to our interest.

I wonder if Professor Winslow, with his broad experience in the field of ventilation and industrial hygiene, has any comment to make on the present status of this effort to disinfect the atmosphere, especially as it may be used in conjunction with the ultra-violet light method.

PROFESSOR WINSLOW: I have just finished an attempt to review the history of epidemiological thinking, the last chapter of which deals with Chapin's modes of infection, and I have come to the conclusion, in writing that chapter, that the one new principle that has altered our conceptions of epidemiology since 1910 was this discovery of the wider range of atmospheric transmission. I think the evidence is sufficient to show that under appropriate circumstances the control of this type of infection is desirable, and that it can be accomplished either by the use of ultra-violet radiation or by the use of aerosols. I do not think we know the relative advantages of each under various conditions, but we have two good methods of dealing with atmospheric infection.

CHAIRMAN: Mr. Barron, you were

Chairman of the Engineering Section where you had a paper on the subject of ultra-violet light.

MR. BARRON: Yes. Professor Wells, of the University of Pennsylvania, presented a very interesting paper regarding his observations of the incidence of measles, I believe, and some other communicable diseases under conditions where in one part of several schools, irradiated air had been used and in other parts ordinary ventilation had been used, with quite remarkable differences in the incidence of communicable disease.

CHAIRMAN: You are going to see much more about this in the pages of the AMERICAN JOURNAL OF PUBLIC HEALTH.

Dr. Frobisher, tell us what is new in the field of syphilis serology at this Annual Meeting.

DR. FROBISHER: I sat in on a rather interesting discussion of new methods of the use of the test in syphilis serology, a screening device to eliminate excessive amounts of work in the laboratory, and a study of the verification test. These papers were commented upon by Dr. Kahn of Michigan and his coworkers; Mr. Webb of Georgia read one of these papers. The details of the technic will probably appear in the JOURNAL, so that I think we need not go into that particularly.

I was interested in the argument that arose regarding the reporting of the results of laboratory tests. It seems that many laboratories run several tests: they may run the Kahn test, the Eagle test, the Hinton test, and maybe two or three others, and those tests do not always agree; the physician is sometimes left to find out and to decide for himself whether the patient has syphilis or not. He is often at a loss, and he calls up the laboratory and says: "What do you think? Is this a case of syphilis or isn't it?" And the question came up as to whether the laboratory had a proper

function to summarize and average up the results, all the 4-pluses and 3-pluses and plus-one-and-a-half, and turn out an average result and say: "That is the result . . . we think the patient has syphilis."

I do not think the difficulty was settled while I was there, but it brings up the whole question of laboratory reporting.

The same problem has arisen in connection with reports on typhoid serology, the H and O and Vi agglutination test, and the various titers that are reported, and whether the laboratorian should summarize his report for the physician or leave the physician to wade through it and look up the literature and decide for himself what the report means.

I think it is an open question. There are two decided schools of thought on the matter, and perhaps we might hear an opinion or two before we get through, because apparently the feeling is quite distinct. There was no settlement of the question while I was present, but I think it is a very live one that has to be settled eventually.

CHAIRMAN: Dr. Baumgartner, will you give us a brief resumé of what happened in the round tables of the Maternal and Child Health Section, where various kinds of pediatric problems came up?

DR. BAUMGARTNER: The chief problem that came up in the round table I attended was the establishment and maintenance of a normal appetite in terms of nutrition. It was interesting that, instead of talking about how to cure babies or school children of not eating properly, the whole emphasis was put on the basis of how to prevent them getting that way at all. I think probably the discussions could be summed up most aptly by saying all the experts who were there thought the baby was more important than the clock. They did not think it was very important any more to be sure the baby was fed a

given number of calories at a given time. They pooch-pooched the idea that the baby was nothing but a calorimeter.

They seemed to think that parents and pediatricians and nurses had gone around not paying much attention to the personality of a baby, paying no attention to his normal appetite, and, probably as a result of many of their admonitions, have just ruined what might normally be a perfectly good appetite in a small child. They pointed out that a baby ought to like to eat, that mealtime should be a pleasing time instead of a battleground or disciplinary period. They pointed out that most children's eating problems came about by mothers being worried that they did not eat. They gave practical hints.

Most pediatricians know well that a child of two does not eat as much as a child of one, but it is hard to convince a mother of this fact. Dr. Casparis says he handles it this way: He says to a mother of a child: "He has tripled his weight in one year, he weighs thirty pounds. Would you like to have him weigh ninety pounds next year?" Then she shudders.

The session was full of practical hints, though I am not sure we can get the participants to write them down so we can get them in the JOURNAL. It is a new approach and, inasmuch as public health people are responsible for the feeding habits of a large number of children, it seems to me important for us to know this new point of view in the field of pediatrics.

CHAIRMAN: Dr. Baumgartner, would you say we had a device here in terms of these round tables that we ought to use again? I understand this device has been used by the Academy of Pediatrics. Do you think it suits our needs?

DR. BAUMGARTNER: It certainly suited our needs in the session I attended. How was it in your section, Dr. Deitrick?

DR. DEITRICK: We had to cancel one

round table of our three because the leader was called to Washington. Both round tables were considered very satisfactory.

CHAIRMAN: The Program Committee is going to consider that idea of the further use of round tables. Was the number in attendance limited, Dr. Deitrick?

DR. DEITRICK: Yes, it was. We tried to limit it to forty-five, but fifty-two crept in to one of the sessions.

CHAIRMAN: Dr. Perkins, what happened in that paper I hear so much about in the Epidemiology Section on this matter of water supplies and infantile paralysis?

DR. PERKINS: Dr. Kenneth F. Maxcy of Johns Hopkins University presented his paper in such a scholarly manner that I hesitate very much to attempt to interpret it and summarize it for you.

Dr. Maxcy first pointed out that certain data, which for the most part have been accumulated in recent years and are largely of a laboratory nature, are apparently consistent with the possibility of poliomyelitis being transmitted through water supplies. Some of these data are the finding of poliomyelitis virus in the stools of cases, contacts of cases, of other individuals in the community; and the isolation of the virus from sewage coming from hospitals in which there had been poliomyelitis cases, and even sewage draining certain communities in which poliomyelitis cases had occurred.

Then he pointed out that certain strains of the virus apparently are resistant to chlorination in the doses ordinarily used in the treatment of water supplies. He further stated that, although it had not been published as yet, a manuscript had come to his attention which seemed to indicate that the virus could survive passing through purification processes ordinarily used in the treatment of water supplies.

He then went on to say that, in spite

of these data which are consistent with that possibility, the pattern of spread of poliomyelitis in nature does not suggest that it is usually spread through water supplies. He substantiated his statement by various points, such as that there had not appeared in the literature a report of a large outbreak having the well known characteristics of a water-borne outbreak. He stated that usually there is a predilection for rural areas rather than city areas; that even here it spreads out in a radial manner and apparently is not influenced by the local water supplies involved.

He also pointed out that, even though perhaps occasionally it might be spread via water, this would not justify classification as a water-borne disease, and gave as examples tularemia in Russia and Turkey, which has occurred there as a water-borne disease, though ordinarily it is not so considered. The brucellosis outbreak in East Lansing, Mich., and the amebic dysentery outbreak in Chicago, were also cited as unusual instances of water-borne transmission of diseases not ordinarily transmitted in this manner.

CHAIRMAN: You may recall that the definitive article describing the outbreak of brucellosis in East Lansing appeared in the *AMERICAN JOURNAL OF PUBLIC HEALTH*. Dr. Perkins, does Dr. Maxcy's conclusion check with your experience in New York State?

DR. PERKINS: Yes, and with our experience in Minnesota.

CHAIRMAN: Mr. Morton, you had a paper on "The Epidemiological Basis of Environmental Sanitation." Please tell us about that.

MR. MORTON: In a symposium, Dr. Gaylord Anderson presented a paper on "The Epidemiological Basis of Environmental Sanitation." In this paper he showed by example that some procedures of environmental sanitation cannot be justified on an epidemiological basis. He therefore made a plea for better

analysis of the program, and especially when faced with any reduction of service available he recommended that the selection of things to be done should relate to their epidemiological or direct public health value.

He did not advocate throwing over all esthetic values. He said that, if esthetic values can be maintained without sacrificing something which by the analytical approach which he recommended had been found more valuable, they should be maintained. In other words, if you can retain the most valuable things and still have some of the values left that are desirable because they are decent, he did not object. It was a very useful, a very interesting, and stimulating paper in urging a more thoughtful approach to environmental sanitation.

CHAIRMAN: Mr. Thomas Stowell of the New York State Department of Health, who has been in charge of the motion picture theater here has just come in. Mr. Stowell, what were the highlights of the motion picture exhibits? What new things have you seen there? Don't be afraid to include some of your own New York State films that are good.

MR. STOWELL: This year again we have found an unusual interest and a hunger and thirst for nutritional films, good nutritional films; and in that connection we found a great deal of interest in a new film produced by the St. Louis Dairy Council on "Making Ends Meet," and in "Hidden Hunger," the national nutritional film. It was quite interesting that two of the most popular films that we exhibited were Canadian films, one from the Saskatchewan Cancer Commission, a new cancer film, "That They May Live," and another "Food, Weapon of Conquest," produced by the National Film Board.

There was interest also in "Local Health Problems in War Project Areas," which illustrates problems arising in New York State when a large war proj-

ect entered a very small community. Another film, "The Ominous Arms Case," on back siphonage gotten out by the plumbing industry, created a great deal of comment.

One other thing I think was quite noticeable this year: an interest and a demand for dental hygiene films, which was partially met by a new film from the American Dental Association, called: "Our Teeth." As to scientific films, we had one session on films designed for professional audiences only, and of the sessions we had, I think that it had the lowest attendance, so I am wondering whether that is really worth while.

CHAIRMAN: Mr. Stowell, is the silent film entirely out of the picture now for health departments and voluntary agencies, or is there some use still for the silent film?

MR. STOWELL: I should say there is still a great use for the silent film, especially in more or less technical subjects; especially the silent film for organizations that want to produce their own films, and I think that is to be very much encouraged, too. We had a film from San Jose, Calif., on "Home Nursing"; they tell me that they felt the definite lack of a good home nursing film, so they made one. Although it has technical disadvantages, I think, it still is not a bad job at all; that was made silent and will serve a very definite purpose.

CHAIRMAN: Is color a necessity in films of that sort?

MR. STOWELL: Not at all. Color is advisable in films that you expect to show to lay audiences, of course, especially from the West. I understand they do not like to look at pictures around California unless they are colored, but in the East we do not find that difficulty.

CHAIRMAN: You of the audience must not expect us here in this review, of course, to be exhaustive; we have no intention of taking up every important paper here, and if we give dispropor-

tionate emphasis to one subject, please remember that we will hope to balance that emphasis through the JOURNAL and in other ways.

While we have Dr. Haralson here, the Territorial Health Officer of Hawaii, who is facing tropical diseases, if Dr. Frobisher will tell us what new light on tropical diseases came out in this meeting, then we will get Dr. Haralson to comment and perhaps include some other angles which the emergency in Honolulu has brought to his attention. Dr. Frobisher, will you open the subject?

DR. FROBISHER: Yes. The first mention of it that I heard was a talk by Dr. Hitchens, who regretted the lack of good general training in tropical disease, in men coming into the medical corps in the Army, and hoped that it might become more extensive.

The point was brought out also that there was a real possibility of the tropical diseases becoming ectotropical, so to speak, on the return of troops from tropical regions where these so-called exotic diseases exist. The question comes up, for example: when is a tropical disease not a tropical disease? It may not be a tropical disease when some of these people return from infected regions.

In discussing this matter with the other members of the editorial staff, the point was made that these men may bring back these tropical diseases, but they do not bring back with them the vectors, so that the danger is perhaps not so great. A man bringing a transmissible disease into an area where there is a related insect vector is a considerable menace, but the mere return of a man from the tropics to some northern area is not necessarily a menace.

CHAIRMAN: Dr. Mustard, which of the so-called tropical diseases do you regard as really important as you select papers for the JOURNAL?

DR. MUSTARD: In our JOURNAL we do not cover the more, shall we say,

exotic tropical diseases. We recognize that, with returning troops, opening up of commerce, etc., we may have flares of these rare diseases in this country, but for the great mass of public health workers and, I think actually for the people who are going with the armed services into the tropics, we of the JOURNAL are concerned primarily with giving information about two diseases. One of those is malaria, and the other is dysentery, and I think if the average individual can get himself thoroughly steeped in such knowledge as is available on the causes, control, and treatment of malaria and dysentery, he will have broken the back of that problem. If he does not, it will break his back. It is those two diseases that we should be principally interested in, but not necessarily exclusively, in connection with tropical diseases.

CHAIRMAN: Thank you, Dr. Mustard. Now, Dr. Haralson, how does this whole subject come to bear on your whole problem in Hawaii?

DR. HARALSON: Well, in the Territory of Hawaii, fortunately, so far as malaria is concerned, we do not have the vector; we do not have the *Anopheles* mosquito. It is a subject of very great concern, however, because we have no idea as to why we do not have the vector. Undoubtedly, *Anopheles* mosquitoes have been brought there in times gone by, but for some reason they no longer breed, or did not breed, in the Territory. I can theorize on the subject, but I have no answer.

We have had for a number of years an occasional case of malaria reported. We usually are able to trace that patient back to some outside malarial area. Since we have a larger concentration of troops out there at the present time than we have had in recent years, to say the least, we have had a number of cases of malaria, but they have all occurred, however, in troops from the mainland, and military authorities are

taking every possible precaution because, of course, we might get an *Anopheles* mosquito.

We do have the vector for yellow fever, but through good fortune, or good work on the part of the Quarantine Service, we have not had any yellow fever.

CHAIRMAN: How about dengue?

DR. HARALSON: We have not had any dengue for a long time, but we do have the vector. I do not know whether dengue is present in the Islands of the Southwest Pacific; I believe it is in the Philippines. Some twenty-odd years ago, I understand, we had a severe epidemic of dengue. So, for those principal diseases, we are just living in hopes and passing the ammunition.

We do have a couple of conditions that worry us. We have typhus fever and we have bubonic plague. Last year, we reported more cases of typhus than we ever reported before. Some of us question whether there has been an increase in number of patients or whether we are getting better reporting; we think we are getting better reporting.

It is the rat-borne variety and, of course, the eradication of that is theoretically simple: just eradicate the rat, and we will control it. I have been told since I came to the mainland on this short trip, that we had to get down to business and eradicate the rat. So, I issued cordial invitations to these experts and asked them to come out and lend a little assistance. You, friends on the mainland, have a cordial invitation to come out and give us some assistance, where rats breed out in the open and in the canefields, and there are plenty of tropical fruits and foods of all varieties to allow them to propagate in numbers.

So far as dysentery is concerned, in some areas some of us have no particular fear. Of course, from the military standpoint, this is one of the most disturbing possibilities. And since we have troops fairly well scattered over the

area of the Territory, the water supply and sewage disposal is, of course, a subject of considerable moment. There has been very close coöperation between the military authorities and our own local health departments and water boards, in doing everything possible to provide safe supplies. In spite of this, however, we know that we have so many supplies that are not properly protected that we do have fears. Fortunately, up to the present time, we have certainly had no outbreak of widespread importance.

CHAIRMAN: Thank you, Dr. Haralson. The JOURNAL recently has brought you word from the front line in Hawaii and in Alaska. We carried a paper by Dr. Courtney Smith on the work that is being done in the Territory of Alaska. We will try to keep alert on things that are happening on the firing line.

Dr. Haralson, as you go back to Hawaii, you carry our greetings with you, and we hope the news from there is going to continue to be good. Dr. Haralson has the only unit under the American flag where compulsory vaccination against smallpox and against typhoid fever has been uniformly enforced. Is that correct?

DR. HARALSON: I do not know whether that is correct. We did have enforced vaccination under military order, which was not as serious as it sounded, but I think if we, throughout the country, could get the people to appreciate the necessity of compliance with our own regulations as easily as we apparently did out there in connection with the military regulation, there would be no difficulty whatsoever in getting this very desirable result accomplished.

As a matter of fact, we had no sections or groups who objected. We know practically all of those whom we vaccinated because shortly before the vaccination was done, the entire population had been enumerated and registered and had been given identification cards—I

carry my own—and when they appeared for vaccination, a record was made. When we checked up and they had not appeared, we simply sent a message by a neighbor or friend. But, had it not been for that order, which at the present time they accept without question, that is, military order, we would probably have had the same difficulties and troubles that most of us experienced in times gone by. We claim something like ninety-five per cent against those two diseases and a considerable number against diphtheria, which was not required.

CHAIRMAN: Thank you, Dr. Haralson. Our best wishes go with you.

CHAIRMAN: We got away from the subject of tropical disease a moment before we intended. I would like to ask Dr. Henry Meleney, a member of the editorial board of our JOURNAL, whether in his specialty of tropical medicine he can throw any light on what we have learned here.

DR. MELENEY: I cannot add anything out of the meeting here today, but at a meeting of the Association of American Medical Colleges earlier in the week, approval was given to a plan for subsidizing staff members of the medical schools, who need further training in tropical medicine and parasitology, in order to conduct satisfactory instruction in their schools, and to provide for their attendance at special courses for this purpose within the next year; and I hope that will improve the teaching in the medical schools.

Dr. Mustard, will you say a word on the studies of local health units and the extent to which these seem desirable?

DR. MUSTARD: I should be very happy to talk about that, but I happened to see Dr. Haven Emerson in the audience. He is chairman of this subcommittee of the Committee on Administrative Practice, immediately concerned with that problem of nation-wide service and how it must be handled. I

should beg you direct your question to Dr. Haven Emerson.

(In the absence of Dr. Emerson, Dr. Mustard continued.)

DR. MUSTARD: I think there has been an increasing interest among public health workers not only in the amount of territory in the United States which is provided with reasonably adequate service, but there has arisen this new interest in what is to be done and how it is to be done in those still rather vast areas where the public health service is little better than it was a hundred years ago. And it is with the idea of studying geography, of studying square mile areas, of studying state laws, of studying budgets available, population concentrations, etc., that this committee, of which Dr. Emerson is Chairman, has been put to work.

Many of you, I am sure, saw the large folder which they had in an exhibit here with existing and proposed districts for the various states. I am sure that one who comes from any individual state and looks at those districts would be unlikely to agree that those particular red lines are the ones which should divide the state up into administrative districts or areas. And yet, even if we can start an argument and continue the thinking and action, I believe this committee of Dr. Emerson's will be, shall we say, the catalyst which will bring about finally this nation-wide service.

I think there is no doubt we have lagged somewhat and forgotten the people who were not served, being too much concerned with what we have already done. A reflection of that interest was to be found in a discussion the other day at this meeting, the debate on what type of health unit should be used in the United States.

CHAIRMAN: Thank you, Dr. Mustard. Some of us think there is significance in these units as they may help us to forecast the number of people who will be necessary for staffing adequately the

units across the country. You will remember that the Association passed a resolution, yesterday, saying in effect that we felt that all areas of this country should have adequate, full-time local health service. That is similar to a very significant resolution passed by the American Medical Association at its meeting in June.

CHAIRMAN: Dr. Louis I. Dublin is Chairman of a Committee on the Study of Voluntary Health Agencies, which reported this morning. I wonder whether Dr. Dublin would give us in a capsule the significant developments in that field.

DR. DUBLIN: Mr. Chairman, the first meeting under the auspices of the American Public Health Association of anything that looks like a study in the voluntary health field took place this morning. We had an hour, we had four speakers, there was an audience of perhaps 300, who seemed to be thoroughly interested in what was presented. The important point that was made was this: here is a vast field of health work which has heretofore received no concerted study; the field has grown up like Topsy; it represents a thoroughly American movement. If it could be summed up altogether, it might amount in terms of dollars to as much as was spent for official health work in the United States; in terms of time and effort, it would undoubtedly go way beyond the amount of health work done by official agencies. In terms of effectiveness—well, who knows? But here it is, a great big movement, spontaneous, full of human interest, involving the good will of millions of people, and a great big question mark as to what it is doing.

It was felt that the time had come for that sort of thing to be investigated, studied, analyzed, tied up to the official agencies, if you will; fundamental questions asked as to standards, as to inter-relationships between voluntary agencies themselves.

In this particular health activity, we have sometimes multiple developments; in one community, fifteen agencies engage in the care of crippled children. In the field of mental hygiene, much the same story. Questions that are in the mind of everyone are something like this: How are they related to each other? Do they stand in each other's way? Do they coöperate? Do they help the health officer? What does the health officer think about them? Are they really a part of the machinery of public health in America? These are the questions that are being attacked.

Selskar Gunn, a man of extraordinary ability, with a fine background, is giving his full time, all his energy, to attacking this problem. He has Philip Platt working with him; he has a good committee, and I think he has aroused the interest and good will of a large number of our people who in their own communities will now begin to ask questions; begin to look into their own situation; write back; call for help; they say: "Help us to formulate the sense of this thing." And we hope by the time this study, which is launched on a three year basis, is completed, we will know something about this giant.

If I am to take advantage of this grand opportunity, I bespeak for this effort your good will. Keep in touch with Selskar Gunn and Philip Platt, write to the National Health Council; raise issues; tell us of the problems you have; and if you get inquiries in the form of questionnaires to fill out, please help us and do it.

CHAIRMAN: Thank you, Dr. Dublin. I am going to enlist Dr. Dublin's help to get us a manuscript on this subject. Our efforts so far from the study staff have found them so absorbed in the job of getting the work done that we have not been able to give you manuscripts through the JOURNAL, but we have standing requests for those, and we hope to produce.

There are two large fields of interest here that have not yet had even slight attention, and I am thinking particularly of the public health nurses. The nurses here had interesting programs, not only separately for the Section but joint sessions with other Sections. I wonder whether Miss Dorothy Rood, of the University of Pittsburgh, would care to summarize the highlights from the public health nursing standpoint.

Miss Rood: One thing that stands out to me as a real highlight in nursing is the Curriculum Guide which has been prepared under the auspices of the U. S. Public Health Service and the N.O.P.H.N. The nutritional section of that guide was discussed in one of the meetings. I believe it offers an instrument which has not been presented in any other field, a study of what should go into the content of the training of a public health nurse. I think it has wide usefulness for health officers and others, as well as for those of us for whom it was prepared—those of us who are preparing nurses for public health work.

Another aspect was the field of community planning, and I think that planning must be done for the private nurses, the subsidiary groups and student nurses; and each community must be studied to see how and where the services would be carried by the ones who are left in the community.

Out of that grew a resolution which was passed by the Association yesterday, which I think had far reaching influence in nursing and in the programs of nursing, and that is that bedside care should be considered as an integral part of the nursing program—that it is important for health departments and the official agencies to include bedside care, just as much as the private agencies, in their program.

I think these constitute probably the greatest highlights that we have had, except for one current that I think has

run through all the sessions: the need of keeping on with the professional education of our young people, especially when our young nurses are going into the armed forces, we must recruit enough to keep on with our programs. We must keep on training personnel, so that we will not be short in the years immediately following the war.

CHAIRMAN: While we are on this subject, will Miss Dorothy Deming give us a resumé of the special session on Merit Systems?

MISS DEMING: We met in a rather small meeting to discuss what the A.P.H.A. is doing in the field of the Merit System. We discussed the matter from two points of view: (1) the rather intimate one as to what the A.P.H.A. can do for the Merit System supervisors in providing examination material for the examining of personnel in the states; (2) which was less intimate and a very general discussion, on what is the matter with the Merit System? what is good about it? what is bad about it? Do we want one?

As the result of a very lively discussion, we came to the conclusion that now more than ever before is the chance to train and to assign jobs to qualified personnel; partly because, if we are sharing our present personnel with the armed forces, the weight of responsibility must be carried by even better trained people than formerly. And, because when the war is over and the troops begin coming back, not only must we have trained personnel on the job to continue a high level of service, but we must be ready with the Merit System running and functioning, in order that the goal of qualified personnel appointed on the Merit System basis should be an actuality and not just a dream, which it has been for so many years.

We had the pleasure of having with us representatives from the U. S. Children's Bureau, Dr. Eliot, Miss Blakelee, and Dr. Dailey, and the members

of the consultant nursing staff of both the U. S. Public Health Service and the Children's Bureau; so that it was a true meeting of the groups concerned with the administering, the functioning, and the actual working out of the Merit System as it has been set up for us by the federal groups.

CHAIRMAN: Miss Deming might have gone on to tell you that Merit System questions are now available to the State Merit System Agencies for public health nurses, and now we are moving out into other fields in which shortly we shall have questions ready.

Miss Deming's associate in working in this field, and mine, is Dr. Mary Steichen, but in view of the shortness of the time, I am going to ask Dr. Steichen not to go on with this Merit System study, which some of us think is one of the high-water marks of the Annual Meeting, but instead to give us a resumé of what she heard at the luncheon session at which Sir John Orr of Aberdeen, Scotland, spoke.

DR. STEICHEN: One could have listened to Sir John with two attitudes: you could sit back complacently and say: "Let's see what they are doing on the other side?" Or, you could listen with a receptive attitude and say: "What have you got to give us, Sir John, that we can use?"

I think some of you who heard Sir John will agree that he mentioned several factors which certainly we could take over and take over fast. He mentioned, for instance, that everybody was concerned—everybody, men, women, and children—in increased food production. That is a job for all of us, and I imagine it will be undertaken and is being undertaken under the County Agents of the Department of Agriculture.

He mentioned the increased efficiency of distribution and rationing of foods, and I think people in this country are going to welcome the rationing of foods, because it will lead to a better and more

equitable distribution of the more vital elements of nutrition.

I was particularly interested in the description of the national loaf of bread which was established by the government; it sounds good to me, everybody who has tasted it says it is the best bread he has ever eaten.

Then there is the extra free rationing of very vital foods such as milk and eggs to mothers and children. We have got to come to that. That, plus the communal meal for all workers, leads to the conception of a leveling of the national diet: the poor people will come up and the richer people, who certainly do not need to be fed any better than they are as far as quantity is concerned, but often need to be fed better as far as quality is concerned, will come down until there is a broader scale of good nutrition.

The most important thing I got out of his address was that it reminded me of a school I know which burned down. It was a great disaster to the whole community, because the children and the parents were very much concerned with that school. The next day after the fire, every class met, and from then on it was a progressive learning process, a constructive use of a disaster for every single person in that school. So, by the time the school was rebuilt, the older children had taken part in construction; they knew what heating and ventilating meant; the little children had learned arithmetic by figuring what the school cost, etc.

Of course, you cannot burn a school down to provide a good constructive experience, just as nobody wants a war, but we can turn this war into a vital and lively experience if we use it constructively. I think that is what Sir John had in mind when he said that the medical profession should take up the cudgels and plan what they are going to do next, so the measures we take now will lead into a wider and more efficient

scale of achievement in public health.

CHAIRMAN: We should now look at the field of industrial hygiene and pick up a few of the high spots. Dr. Leonard Greenburg is here, a member of the council of that Section. Dr. Greenburg is in charge of industrial hygiene under the State Department of Labor in New York.

DR. GREENBURG: Mr. Chairman, in my opinion, the outstanding new development discussed by the Industrial Hygiene Section revolved around the question of nutrition and eating facilities for industrial workers. Dr. Boudreau presented a beautiful discussion of this subject, based on his research studies on the nutritional status of workers in selected industries.

There is clear indication that the nutritional status is far below anything which should be called adequate or desirable, and steps must be taken as soon as possible to provide more satisfactory diets for our American workers.

In the British experience, this followed along two general lines, and it would appear that in our American experience we will have to do the same thing—(1) the widespread use of publicity material, and (2) some kind of voluntary and official introduction of eating facilities and food into industry. The British law now requires that all plants having 250 or more workers be provided with a canteen. In the United States, there are no legal requirements in any state of the Union, and serious consideration must be given to this aspect of this important problem at the earliest possible moment.

There was a very interesting paper on the first survey of industrial nursing in America being made by a number of states in coöperation with the U. S. Public Health Service. The speaker provided a resumé of the results of 700 factory investigations along these lines. I think the Public Health Service will publish a bulletin on this subject, and

perhaps our JOURNAL will include such a paper. So far very little is known quantitatively about the status of industrial nursing in America.

There were several other interesting papers. The first recent paper to appear on the basic chemicals used in synthetic rubber, especially a substance known as styrene, and one of the workers from an important chemical company in this country presented a discussion of the toxic effects of styrene.

There were other good papers, on the training of industrial hygiene personnel, which leads one to believe that the pool, at the present time, is very limited, and we have been stumbling in our efforts to divide up the present personnel resources. It seems to me that we have been lacking in a certain degree of planning.

Mr. Chairman, if I may revert to one other question, which does not concern industrial hygiene, I would like to mention for a moment this question of sterilization of the atmosphere. Some years ago, I had the opportunity of studying an epidemic of cerebrospinal meningitis that took place between Manila and Honolulu, and the persons who were subjected to the epidemic and the victims of the epidemic, during which the mortality at times was 26 per cent; were transported on ships between the Philippine Islands and Honolulu. I was startled the other day, when I saw pictures of our American boys being transported in vessels of this same type, under similar crowded conditions, and I believe that this is a direct challenge for action by the American Army and the American Navy.

I think whatever we know about the sterilization of the atmosphere should, if it is safe, be put into effect under these unusual conditions when we are transporting large numbers of soldiers and sailors across the ocean, under conditions of severe crowding.

I cannot close without mentioning Dr.

Merewether's very interesting discussion at our luncheon. He told us how the British, without elaborate schemes of administrative diagrams but apparently with more persuasive and effectual personnel, had done a wonderful job in keeping factories safely going in Great Britain under the most trying conditions.

CHAIRMAN: Thank you, Dr. Greenburg. I am glad you called attention to Dr. Merewether's contribution. We also appreciate Dr. William Frazer's presence here. I do not see him in the audience, but you will find a very interesting manuscript by him in the December issue of the AMERICAN JOURNAL OF PUBLIC HEALTH, the manuscript which he abstracted in a session before the Health Officers Section at this meeting.

I call now on Dr. Baumgartner to tell us about birth records and vital statistics, and new uses that can be made of them in administrative service.

DR. BAUMGARTNER: This was a very interesting session, a joint session of the Vital Statistics Section and the American Association of Registration Executives. Birth certificates apparently have come of age and are serving various administrative uses. All of us are used to thinking of them as ways of finding out whether people put drops in babies' eyes, or sometimes we think of them as tools by which we can follow congenital lues. Some of us think of the weight that is recorded on birth certificates as a record of where premature babies are and send visiting nurses to visit them. Some of us have learned to find out about crippling conditions of children in this way, thus adding the names to crippled children's registries.

All of these were pointed out in this meeting, but the new use was to see a large map of Connecticut and on this map to see where the new babies had been born, and see the Connecticut State Health Department apparently planning where to send in more personnel, be-

cause more babies had been born down in this corner as a result of migrations to defense industries. Apparently birth certificates have a lot of uses aside from filing them in books.

CHAIRMAN: Thank you. I introduce now the Commissioner of Health of St. Louis, Dr. Bredeck. I would like to ask you whether, during the time you have made such a contribution to our comfort and convenience here, St. Louis and your Health Department have been able to get anything out of this Annual Meeting. I would like to pay a very sincere tribute to Dr. Bredeck. He has been our host here in a most acceptable way and, on behalf of the Association staff and on behalf of you all, I suggest that we give him a salute (applause for Dr. Bredeck).

DR. BREDECK: Thank you very much. Of course, the local health officer is interested in having a convention, for two purposes: In the first place, he feels a good deal like the cow who has been on the pasture too long until she grows thin. Another is that like the fellow who plays the same phonographic record too long: the listeners get tired of it. I have been talking public health in this community for a number of years, and I get the impression that they are getting tired of the record, and during this convention, I and other members of the department have learned a number of new ways of saying things and, of course, we are perfectly selfish about wanting you here.

We need the stimulation in this section of the country, and we have not looked upon it as a convention only for St. Louis, but the surrounding areas, East St. Louis and the County, the State of Missouri and the surrounding territory. And I have already seen the stimulation that occurs locally from such a meeting. People wonder why we do not get tired at the convention. Well, when you wait seventeen years for a convention, you can stand it much

longer than two weeks, and you go through it without feeling tired at all, because this will have definite beneficial effects in many ways locally.

And, of course, being somewhat of an optimist—and I think that is the only way you can get anywhere—we feel very much indebted in having the convention. I say that not only for myself but for all of those associated with related fields in public health. And as I stated the other evening, I hope our next convention will be here before another seventeen years. Thank you.

CHAIRMAN: Thank you, Dr. Bredeck. Is Dr. McGavran in the audience? I would like to have him take a bow. He is the Health Officer of St. Louis County, to whom we are also indebted, with his staff, who have worked so closely with Dr. Bredeck and his staff. At any rate, we give him a greeting and our renewed appreciation supplements what we said yesterday.

We have come to the closing moment. There are several live subjects here on which our participants have said they would be willing to comment. I am sorry to have to bring it to a close, but I know some of you have train appointments. There are two papers which Dr. Perkins said this morning he would like to comment on, one was on the subject of dental caries and the angle of its epidemiology. That appeared in the November issue of the AMERICAN JOURNAL OF PUBLIC HEALTH. He spoke to me about another paper, that by Drs. Twinam and Pope, on the subject of a clear-cut tuberculosis outbreak; that too is in the November issue.

Now, the Editorial Board, the editorial staff, and the Program Committee would be glad to have you express your opinion as to whether you like this kind of a wind-up session, or whether you would prefer to bring the meeting to a close on the subject of our special interests as distinguished from our common interests. We would be glad to

THE 71ST ANNUAL MEETING

1399

hear your comments, because, if you want this kind of a thing, perhaps we can do it again.

I thank you for your undivided attention and tell you that, as we bring to a close the final session of this Seventy-first Annual Meeting, it is with a feel-

ing of mutual interdependence that we go home, ready to carry on and meet whatever situations we are faced with, always knowing that we have this body of colleagues and this kind of support that will carry us through whatever comes.

INSTRUCTION OF MEDICAL STUDENTS IN PREVENTIVE MEDICINE AND PUBLIC HEALTH

IN the latter part of October the meeting of the Association of American Medical Colleges and the meeting of the American Public Health Association overlapped to some extent. This, however, is not the important thing in relation to the October gathering of the members of these associations. What is important is the fact that each gave serious consideration to the question of instruction of medical students in preventive medicine and public health: what should be taught, and when it should be taught, and how.

The need for such consideration has long been obvious, and some three years ago the Association of the American Medical Colleges, at the request of the American Public Health Association, appointed a committee to work jointly with a similar committee of the latter organization to the end that there might be formulated jointly a program for instruction of medical students in preventive medicine and public health. Progress to date has consisted of: (1) a study of the problem as it is found in the various medical schools of the United States and Canada, and (2) collecting of documents which, on analysis, provide a cross-section of opinions of the majority of professors of preventive medicine and public health as to what is good and what is bad in the present situation, and what needs to be done about it. A report covering factual material was published in the April, 1941, issue of the *Journal of the Association of American Medical Colleges*, and at the October meeting of that association there was presented a summary of the opinions referred to above. The American Public Health Association for its part made this subject the theme of the meeting of its Committee on Professional Education, and in addition provided on its program for a panel discussion of this subject by those who actually teach it.

It appears then that this important subject is in the process of receiving the attention which it has merited. The committees concerned have received due encouragement from their respective organizations and, it is to be hoped, will act with such expedition as may seem wise under war conditions. They must,

of course, recognize on the one hand that all medical schools are at present harassed by accelerated programs, and by depleted faculties, and that there looms for the future a group of students not as mature as in the past, and perhaps to be selected by means not the most desirable. In view of these difficulties, the pressing of recommendations for immediate curriculum changes might at this time be inopportune. On the other hand, and in spite of the bedeviling things just mentioned, the committees will need to bear in mind that future graduates in medicine will go almost immediately into military service where the prevention of disease and mass medical service will loom larger than in civilian practice. In addition, it is possible that adjustments in the post-war period may carry newer responsibilities and newer concepts even into private practice, and thus for future civilian as well as for immediate military needs, the committees concerned may find it desirable to formulate rather quickly some general guide for instruction of medical students in preventive medicine and public health. But whether such a program is presented immediately or at a later date, the previous work of these committees leads one to believe that they will, in their final recommendations, remain practical; that there will be no tendency to impose a frozen teaching pattern on all medical schools; that they will recognize that medical schools differ in interests, organization, and resources, and will concede that, inasmuch as content, quantity, and quality of teaching in such departments as medicine and surgery vary from one medical school to another, so must there be differences in the teaching of preventive medicine and public health.

The matter has now reached a stage where one may well feel encouraged. The future work of these committees will be watched with interest.

WANTED: A BIOPSY ON COMMITTEES AND BOARDS

THE Editor wants very much to publish in the *Journal* a paper on the subject of committees and boards; a paper that will exhibit their structure, and function, their anatomy and physiology, their "positive health" and their pathology. *Journal* readers, therefore, are invited to submit manuscripts on this subject. The two adjudged most satisfactory by the Editorial Staff will be published in the early summer. The deadline date is April 30, 1943. Manuscripts must be received by noon of that day.

We send out this call because we consider the matter important. Public health workers, particularly in the voluntary agency field, luxuriate in committees, are possibly addicted to them. Given almost any opportunity or even an excuse, and the health organization goes into a sort of parthenogenetic spasm and delivers itself of a full-blown committee which, in turn, tends to exhibit an amazing immortality. But it is not with these phenomena *per se*, that one need be concerned, for admittedly, small groups must from time to time act for large ones: for exploration of new subjects, for review of old ones, for establishment of policies, for maintenance of relationships, for liaison, for swift and definitive action.

Those who accept this invitation then, need not attempt to make a case for committees and boards: their necessity is generally conceded. The matter on which light is needed is a quite different thing, and has to do with the composition of committees in relation to their functions. Does there exist someone seasoned and weatherbeaten in public health committee work, who has acquired through

this process or retains in spite of it, an ability to analyze, classify, and philosophize in simple language, understandable to other people? Can that same person get across to his or her colleagues an understanding of the assets and liabilities of a committee each of whose members represents some special interest, and indicate what may be expected of a board of professionals, or of a council or intelligent persons serving neither as experts nor as delegates? It would be too much to expect this person for whom we are searching to prophesy just what might be born of a committee composed of all these ingredients; but because many of our public health committees are thus hybrid and hashlike in membership, we may hope that information will be forthcoming as to the circumstances and objectives which would indicate one type of membership or another. We, as Editor, have no convictions. We have seen boards of experts act scientifically but entirely in a vacuum; and we have naïvely attempted to get action out of committees in which age, sex, race, residence, religion, and occupation were in proportions seen only in the epidemiology of syphilis.

From where, and whom will come this taxonomy of committees and boards? Who will develop a document which will guide the health officer and the local executive secretary in the matter of committee appointments? Has the West Coast, New England, or the Deep South, or possibly the Middle West, a son or a daughter who will lead public health out of the wilderness of committee chaos?

We most distinctly do not want mere descriptions of how committees and boards are organized here or there, and we shall give scant attention to manuscripts propped up by categorical statements, adjectives, and adverbs. Please avoid the use of the word "dynamic." What we hope for is at least two penetrating, analytic, and judicial essays.

BOOKS AND REPORTS

Chronic Pulmonary Disease in South Wales Coal Miners—Medical Research Council. I. Medical Studies. Including a report by the Committee on Industrial Pulmonary Disease, a Medical Survey by P. D'Arcy Hart and E. A. Aslett, and a Pathological Report by T. H. Belt. London: His Majesty's Stationery Office, 1942. 222 pp. Price, \$3.00.

The high standard set by previous special reports of the Medical Research Council is maintained by this latest contribution on chronic pulmonary disease in Welsh coal miners. In addition to the fact that silicosis is one of the principal industrial diseases in Great Britain, compensation statistics indicate that the main problem of certified silicosis lies in the South Wales anthracite mines. These circumstances determined the selection of this site for an intensive study of the etiological factors influencing the development of pneumoconiosis together with investigations of the clinical and pathological aspects of the disease.

Although the classification of lesions as (a) reticulation, (b) nodulation, and (c) consolidation, differs somewhat from the generally accepted nomenclature, radiological studies indicated that the frequency and degree of pathology were proportional to the occupation, age, and length of exposure of the miners to coal dust. Workers in anthracite mines showed substantially more silicosis than those in the bituminous fields and hard-heading workers developed more lesions than colliers and far more than surface workers. While it seems clear that development of silicosis is closely correlated with the duration and intensity of exposure to silica dust no

attempt apparently was made to measure that hazard in terms of dust concentration, particulate size or silica content of the dust.

The incidence of clinical tuberculosis diagnosed was low; even among miners with advanced pneumoconiosis, and the 95 per cent who reacted to the tuberculin test. In the opinion of local doctors tuberculosis is a less frequent cause of death in silicotic miners than either cardiac failure or non-tuberculous respiratory diseases. No attempt was made to diagnose tuberculosis on radiological appearances in the presence of pneumoconiosis.

Pathologically, pulmonary reticulation is considered as the earliest form of lesion which may be associated with respiratory disability. It is probably a type of fibrosis preceding consolidation but may co-exist with it, and probably is an integral part of silicosis (or anthraco-silicosis). ALTON S. POPE

Intelligence, Power and Personality—By Dr. George Crile. New York: McGraw-Hill, 1941. 347 pp. Price, \$3.00.

George Crile was one of the founders of the Cleveland Clinic, often popularly called the Crile Clinic. He is an internationally known surgeon, the author of many books and papers and the inspiration of many young surgeons. It was he who first made plausible, even though he did so by an inaccurate and incomplete theory, the minimization of emotional shock in certain surgical operations. This is his first book in several years and those of us who have known how hard he has worked on the theory proposed in this book, the collecting and measuring of specimens for

the McBride Museum of the Cleveland Clinic Foundation, have looked forward to it expectantly.

Dr. Crile has tried to correlate the energy requirements of various animals, including man, and many wild animals which he shot and dissected on the spot in various parts of the world, with the weight of the brain, the heart, and the endocrine glands. His data are given *in extenso*; his conclusions are nowhere very explicitly stated. Dr. Crile still further confuses the reader by introducing many vague terms and concepts without taking the trouble to define them or to relate them to previous concepts and definitions. For example, one of his ten biological principles is: "In higher animals, the positive pole of the bipolar mechanism is generated by the brain; the negative pole is generated by the heart and the red blood cells." It may sound like quibbling, but mechanisms are not bipolar and if the metaphor is to be taken from the field of electricity, one cannot say that a pole is generated. The reviewer confesses that this and many other similar paragraphs are incomprehensible to him.

Another sample: "Intelligence, power, and personality are dependent on the absolute and relative size of the brain, the thyroid gland, the heart and blood volume, the celiac ganglia and plexuses, and the adrenal-sympathetic system." The author does not define intelligence and there is no evidence that he is familiar with its definitive and technical meaning in psychological science. Power is certainly too broad a word to use in an unqualified way in such a statement, and personality, which is also not defined, can scarcely be conceived of in such grossly quantitative terms as to be included in a mathematical formula of this kind.

It is interesting to learn that the jaguar has a smaller heart and a larger adrenal than the timberwolf and a thousand other items of carefully col-

lected data of this sort. It is a stimulating theory that in some way the activity patterns of animals can be correlated with brain weight, heart weight, and gland weight. But it cannot be said that this book clearly indicates what this correlation is, or what the meaning of these data is. Psychiatry in particular, and medical science in general would be grateful for any contributions that would clarify the relation of the physical and chemical factors in personality with the psychological factors. This study, unfortunately, does not do so.

KARL MENNINGER

Public Health Nursing Curriculum Guide—Prepared by the Joint Committee of the National Organization for Public Health Nursing and the U. S. Public Health Service. New York: National Organization for Public Health Nursing, 1942. 206 pp. Price, \$2.00.

The *Guide* gives a somewhat detailed statement of desirable goals to be attained in the preparation of public health nurses, with helpful suggestions on educational methods and content. The following areas are covered: I. Introduction to Public Health Nursing; II. Public Health Nursing Services, (1) Maternal Health, (2) Infant Health, (3) Health of the pre-school child, (4) Health of the school child, (5) Industrial Hygiene, (6) Mental health, (7) Nutrition, (8) Oral health, (9) Acute communicable diseases, (10) Tuberculosis, (11) Venereal diseases, (12) Pneumonia, influenza, and the common cold, (13) Cancer, (14) Diabetes, (15) Heart diseases, (16) Orthopedic and plastic conditions; III. Methods of Learning as Related to Public Health Nursing; IV. Public Health Organization and Administration; V. The Field of Professional Work as Related to Public Health Nursing; VI. Public Health Nursing Organization and Administration; VII. Field Experience.

The *Guide* does not attempt to organize the above subjects into definite courses but suggests that they may be integrated into a curriculum as best suits the individual school.

The *Guide* renders a most useful service to those responsible for public health nursing education for it organizes in an authoritative manner the essentials of a public health nursing curriculum. Its educational philosophy and scientific content have been carefully reviewed by leaders in each of the many fields concerned and therefore represent the modern trends in public health. Although this book is intended primarily for persons interested in public health nursing education, it can be read with profit by anyone in the public health field.

H. W. BROWN

Housing Yearbook—1942—*National Association of Housing Officials, Chicago, Publication No. N 159.* 192 pp. Price, \$3.00.

This book is a compilation of a series of articles on housing progress during 1941 by various authorities in the field. Included in this edition are the following articles: Reorganization of Federal Housing Agencies; Division of Defense Housing Coördination Activities in 1941; Mortgage Ownership; A Stimulant to War Housing, Home Ownership, and Housing Standards; The Federal Home Loan Bank Board—1941; Farm Security Administration's Seventh Year in Rural Housing; Defense Housing under the Lanham Act; Housing Activities of the Federal Works Agency; Navy Housing; The Why and How in Housing Priorities; Rent Control Activities of the Federal Government—1941; Central Housing Committee Swan Song; Activities of National Unofficial Housing Agencies and Committees for 1941; Directory of Housing Agencies and an Index.

The present edition is an "economy" edition in that the state and local sec-

tion is omitted along with an account of NAHO's doings and the editors' annual summary.

C. P. STRAUB

The National Formulary—*Prepared by the Committee on National Formulary of the American Pharmaceutical Association. (7th ed.)* Washington: American Pharmaceutical Association, 1942. 690 pp. Price, \$6.00.

Both *The National Formulary VII* and *The United States Pharmacopoeia XII* have a particularly important place in medicine because they are the official sources of information on drugs. Since 1906 the standards for drugs as given in the various editions of these books must be adhered to rigidly by all manufacturers and distributors. On November 1 the new *United States Pharmacopoeia XII* and the *National Formulary VII* will replace the previous editions as standards.

The choice of preparations to be included in *The United States Pharmacopoeia* is determined by the Committee on Scope, who make their decision chiefly on whether or not a particular preparation is of therapeutic value. This is not true of *The National Formulary*. In that book the choice of preparations is determined by the extent to which preparations are prescribed and must therefore be stocked by the dispensary pharmacist. Because certain drugs long since replaced by more effective remedies are still prescribed in large quantities, *The National Formulary* is required to set up standards for them. It is thus we find in it drugs that are not even mentioned in medical college teaching, such as *Aralia* (American spikenard), *Areca* (betelnut), *Buchu*, *Sanguinaria* (blood-root), and true and false unicorn-root.

Great care has been taken by the Committee on Revision of *The National Formulary* to set up standards for each substance included in the book. They have done an excellent job.

By agreement, *The United States Pharmacopoeia* has preference over *The National Formulary* in the inclusion of preparations. For that reason some preparations that were present in the previous edition of *The National Formulary* are now found in *The United States Pharmacopoeia*, for example elixir phenobarbital. On the other hand, a number of pharmaceutical necessities, which include vehicles such as tinctures, elixirs, and waters, are found in *The National Formulary* having previously been in the *Pharmacopoeia*.

ARTHUR C. DEGRAFF

The Pharmacopoeia of the United States of America (12th ed.)—New York: Mack Printing Company, 1942. 880 pp. Price, \$7.50.

It is easy for members of the public health profession to take for granted the uniformity and dependability guaranteed by the U. S. Pharmacopoeia, now issued in a twelfth edition. This is truly a publication of international character of which there has been a Spanish edition for forty years. It is official in Costa Rica, Cuba, the Dominican Republic, in Nicaragua, Panama, the Philippines and Puerto Rico and is used in many other Pan American countries.

Among new U.S.P. items now official there are, among the anti-malarials, Pamaquine Naphthoate, Quinacrine Hydrochloride, Quinine Hydrochloride, Totaquine; among biological products are Human Immune Globulin, Human Measles Immune Serum, Human Scarlet Fever Immune Serum and Tetanus Toxoid new to this edition; the Sulfa drugs include Sulfapyridine, Sulfathiazole and Sulfanilamide; new antiseptics include Chloroazodin and Solution of Iodine. New in the realm of anti-syphilitics are Sulfarsphenamine, Bismuth and Potassium Tartrate, Bismuth Subalicylate and Mercuric Salicylate. Among the new vitamin preparations are Ascorbic Acid, Menadione, Nicotina-

mid, Nicotinic Acid, Rice Polishings, Riboflavin, and Thiamine.

Throughout the volume a commendable adjustment to new discoveries and to current limitations in drug supply is evident. REGINALD M. ATWATER

The Mental Growth of Children from Two to Fourteen Years—By Florence L. Goodenough and Katharine M. Maurer. Minneapolis: University of Minnesota Press, 1942. 130 pp. Price, \$2.50.

As stated in the subtitle, this book is "A Study of the Predictive Value of the Minnesota Preschool Scales," and will be of greatest interest and value, as the foreword suggests, to the "careful student and professional worker in the field of mental measurement." There is, however, much of interest to the medical man who deals with children.

The Minnesota preschool scales for the study of mental development of young children have been in use for some time; they include both verbal and non-verbal scales which are scored separately. In this monograph the authors present a carefully constructed report of the development and validation of the tests which is followed by a study of their predictive value with regard to the later performance of the same children on other commonly used tests. A group of children from two to fourteen years of age was followed and retested at stated intervals. The work and statistical analyses were most carefully done. Evidence is adduced to show that mental development does not always proceed at a fixed rate, and it is suggested that there is a sex difference in the age at which the tests begin to have a predictive value. The superiority of the non-verbal scales over the verbal ones at early ages suggests to the reviewer their use with children whose acquisition of speech is delayed. These children are often brought for advice to the physician who is unable to answer

the parents' anxious question as to whether the child is mentally normal because of the inadequacy of the usual tests. The physician who, in the course of his care of young children, needs to know something of the validity of the usually administered tests, will find much of value in the brief historical survey of mental tests devised for young children.

WILLIAM S. LANGFORD

Youth Looks at Marriage—By M'Ledge Moffett. New York: Association Press, 1941. 48 pp. Price, \$.25.

Health workers who deal with young people will find excellent material in this pamphlet, presented as a guide for discussion groups from adolescence on. The author, who is Dean of Women and Director of Home Making Education at the Radford State Teachers College, Virginia, has succeeded better than others in objectifying this difficult area of marriage and family life. A mature person can hardly read this material without regret that it was not available in his own youth. He will wish to increase the exposure of youth today to this sane approach, especially when the marriage rate touches the present peak.

REGINALD M. ATWATER

The Biological Action of the Vitamins—Edited by E. A. Evans, Jr. Chicago: University of Chicago Press, 1942. 227 pp. Price, \$3.00.

This book contains the fourteen papers presented at the symposium on "The Biological Action of the Vitamins," held in connection with the Fiftieth Anniversary celebration of the University of Chicago, September, 1941.

The material is presented not as a complete review of the field but rather as a series of papers summarizing the recent, most active subjects, each by an author with first-hand knowledge. The purpose has been well accomplished.

After an introductory chapter on

the historical developments of the subject, there follow sections dealing with the biochemistry and physiology of thiamine, riboflavin, nicotinic acid, pyridoxine, pantothenic acid, biotin, choline, phosphorus, and vitamin K. In other chapters clinical aspects have been discussed in relation to thiamine, riboflavin, nicotinic acid, pantothenic acid, and vitamin K. The book is the best single source of information on these aspects of the vitamins now available.

OTTO A. BESSEY

The Sanitary Inspector's Handbook—By Henry H. Clay, F.R., San. I., F.I.S.E.; Major, R.A.M.C. with an introduction by Sir Wilson Jameson, M.A., M.D., F.R.C.P., D.P.H. (Lond.). (5th ed.) London: H. K. Lewis & Co., Ltd., 1942. 534 pp. Price, \$5.25.

A book that justifies its fifth editing in a decade, four editions having been exhausted, must be meeting a real and continuing need in the social order for which it is intended. As Sir Wilson Jameson, Chief Medical Officer of the British Ministry of Health, points out in his introduction to *The Sanitary Inspector's Handbook*, "the office of Sanitary Inspector has become more highly technical and specialized within the British Empire than anywhere else in the world, and the duties for which an inspector is responsible are extremely diverse." It is for the British public health service that the book is intended.

The diverse duties for which the inspector is responsible are introduced at the beginning of each chapter by a summary of the law, so far as it concerns the inspector. There follows an explanation of the technical aspects of the requirements of the law and its by-laws which keeps in mind the second purpose of the author, namely, the preparation of his reader for the examinations that will qualify him for appointment as a sanitary inspector. To that end, systematic outlines that will impress

themselves upon the student's memory are presented, wherever possible, to cover the salient factual information that the student should possess and about which most questions will normally revolve.

This wartime edition of Major Clay's book includes in its technical portions special reference to "conservancy," the British equivalent of our more realistic "excreta disposal," and to camp and rural sanitation, and, otherwise, too, brings the technical information down to date. New legislative enactments that appear to be permanent are added, but emergency enactments that will probably disappear with return to peace are not included. A wartime objective of the book is to meet the special needs of students during the suspension of normal courses of instruction. For the reader in the Americas, *The Sanitary Inspector's Handbook*, because of its close national orientation, is primarily of interest as a reference in comparative public health administration and sanitary legislation. GORDON M. FAIR

The Family in a World at War—
Edited by Sidonie Matsner Gruenberg.
New York: Harper, 1942. 298 pp.
Price, \$2.50.

This is a timely volume conceived and brought to fruition by the board and staff of the Child Study Association of America. It is really a symposium of twenty well written chapters on various phases of family life in relation to the national emergency and national defense. Each chapter bears the marks of special consideration by an authority in his or her particular field. The chapters on "Children of Great Britain in Wartime," by Susan Isaacs, and "The Work of Women in England," by Martha M. Eliot, are especially challenging.

The appendix contains material that should prove very helpful in answering parents' questions as to how they should

meet war conditions. This material has been assembled by the staff of the Child Study Association and the U. S. Children's Bureau. A Commission on Children in Wartime of the U. S. Children's Bureau has prepared the Children's Charter in Wartime.

The editor of this volume in the first chapter sets the stage for the chapters which follow. She is to be congratulated on bringing together so much useful material when the preservation of the family is of paramount concern.

RICHARD A. BOLT

Digest of State and Federal Laws Dealing with Prostitution and Other Sex Offenses—Compiled under the direction of Bascom Johnson by George Gould and Roy E. Dickerson. New York: American Social Hygiene Association, 1942. 453 pp. Price, \$5.00.

Here is a loose-leaf book containing digests of all federal and state laws dealing with prostitution and other sex offenses passed, up to and including September 15, 1941. Note the word loose-leaf, for therein lies the chief value of the book. As new material is gathered from time to time by publishers and distributors the book can be easily kept up-to-date.

Dealing first with the federal laws, then the states, in alphabetical order, the *Digest* presents its material under four headings as follows: (1) Activities of Exploiter of Prostitute Prohibited; (2) Activities of Prostitute or Her Customer Prohibited; (3) Other Sex Offenses Prohibited; (4) Digest of Supplementary Laws.

If nothing more, the *Digest* offers convincing proof of the confusion existing in the minds of both the legislative bodies and the general public, and definitely shows the need for a model law which will be all-embrasive.

Of special interest are the notes on the control of the sale of alcoholic beverages as it relates to prostitution

activities, and the four appendices covering the following subjects: (1) Laws Against Prostitution and Their Use; (2) Essential Provisions of State Laws for the Repression of Prostitution; (3) Milestones in the March against Commercialized Prostitution; (4) Venereal Disease Laws and Regulations; together with information and maps on premarital and prenatal laws of several states.

Containing practical knowledge of ways and means to prevent the "wastage of human resources resulting from prostitution and the undesirable conditions which accompany this evil business," the *Digest* should prove valuable to public health workers, legislators, and research workers.

BEN F. WYMAN

A Brand New Baby—By Margaret A. Stanger. Boston: Beacon Press, 1942. 132 pp. Price, \$1.75.

This attractive book meets a real need which many expectant mothers have experienced in trying to present to young children the important facts relative to birth and care of the newborn with normal development during the first year. The author recognizes that the arrival of a new baby in the home often presents problems in the lives of older children. She has taken into consideration that the bare facts alone do not suffice, but should be clothed for the child in the emotional medium which meets the requirements of modern child psychology.

The story begins in a normal way to interest the child and proceeds step by step to show what may be expected of a new-born baby, and what practical measures should be taken to meet its daily needs. The baby taken as a model in this story has been born in its own home and the procedures taken from the very beginning are somewhat different from those routines carried out in a modern obstetrical hospital. How-

ever, this does not detract from the pedagogical value of the presentation as a whole.

The large type printing and the charming illustrations by Pelagie Doane add a great deal to the book from the standpoint of the child. The book has been written primarily for the six and seven year old children and may be read to them at home or in the elementary grades.

The introduction announces that a guide book to accompany this volume, written by Elizabeth M. Manwell is available.

RICHARD A. BOLT

Red Cross Home Nursing—By Lona L. Trott, R.N., B.S. Philadelphia: Blakiston, 1942. 431 pp. Price, \$.60. Cloth, \$1.00.

The author of *Red Cross Home Nursing* is to be congratulated on covering for the lay reader the fields of health and sickness as capably as she has. With enthusiasm which is contagious, she introduces the reader to the essentials of healthful living and presents, step by step, practical simple procedures for the home nurse to use in caring for the sick. The author wisely refrains from being verbose on a given item but says just enough to whet the appetite of the reader to seek additional information and then she supplies a short list of books for further reading.

The only quarrel we have with this textbook is that its title does not suggest the richness of its content. In fact, approximately one half of the 390 text pages is devoted to factors related to keeping the well person well—to health promotion through individual and community effort. This reviewer makes note of what she considers a misleading title since she was particularly impressed with those units devoted to health.

There are many good points about this text. It is simple, interesting, and easy to understand. The reader is as-

sured of its soundness, for the author lists and frequently quotes her sources from accepted authorities in the various fields covered.

For the most part the text is a nontechnical presentation, but where the use of a technical vocabulary seems necessary the author defines the words in a way that the interested reader will appreciate. The illustrations are helpful. We commend the device of showing what not to do as well as what to do—in the instances where that form of motivation is employed. Finally, the busy housewife will welcome the small number of "Problems for Action" appearing at the end of each chapter. Only three or four are suggested. The fact finding activities should appeal to her and for the most part, the problems suggested are typical of ones the average individual encounters in real life situations, e.g., planning a model kitchen, preparing a budget, and the like.

Red Cross Home Nursing is written, it would appear, for Mrs. John Doe and her daughters. We believe they, and even father and brother, will like the book and want to own it, for it is a veritable mine of authentic information and a reliable index for more if desired.

MARGARET REID

Sex Education in High Schools—
By John Newton Baker, M.A. New York: Emerson Books Inc., 1942. 155 pp. Price, \$2.00.

This book presents the results of a survey showing the experiences of high schools with courses in sex education and our present situation with respect to the teaching of sex hygiene at the secondary school level. Based upon this study of opinion and experience in the field, the book presents a statement of the need, the objectives, the opposition, the methods and technics, the rôle of the teacher, the name of the course, and the benefits of sex education. It discusses the best name for the

course of instruction, the question of segregating the sexes for such instruction, and the desirability of state leadership in the development of this program.

The last two chapters, entitled "The Scene Today" and "Where Do We Go from Here?" respectively, summarize the present situation and the probable next steps. In respect to all of the various topics mentioned, the book presents diverging and opposing viewpoints. It shows that the young people themselves desire such instruction and that the program has been very satisfactory and acceptable in some areas. While there are sharp differences in the attitudes of different states, the survey indicates a tendency toward more and better instruction in sex hygiene. Selected units of study and a selected bibliography are included. The book is clearly written and attractively printed. It presents a good summary of the present situation.

C. E. TURNER

People Are Important—*By Floyd Kuch, Gordon Mackenzie and Margaret McClean. Chicago: Scott, Foresman and Co., 1942. 283 pp. Price, \$1.32.*

This book is as intriguing as its title, and as important as its subject, people. Although a high school text on applied psychology, and therefore outside the usual classification of public health literature, it contains many important lessons for the health teacher and health officer. The oft repeated lament of the late Dr. John L. Pomeroy, 25 years Health Officer of Los Angeles County, "What makes people do as they do?" is answered as fully as can be in this book.

To no one in the community are people more important than to the health officer. Their follies and foibles manifested in bizarre health behavior, together with their energetic health progress when once aroused and organ-

ized, often leave him in a dither of alternating pride and misgiving. If the teaching units in this book should be successfully and generally adopted in the nation's high schools, it will mark the beginning of a new era for health agencies.

Of special value to public health are the chapters for the young citizen on "Learning to Think Straight," and "Getting at the Truth." Here the student is guided into a series of interesting investigations and exercises through which he learns to recognize problems, approach their solution in a logical manner, gather data which are factual, and reach conclusions based on facts, free of bias. When the majority of adults approach their personal and community health problems in this manner public health will flourish. Other sections of related importance in explaining and guiding human behavior are titled "Things that make you go and stop," "Getting into and out of emotions: Emotions are the fabric of life and living," "Getting along with others." Incidentally, it is refreshing to find a school text which recognizes the

importance of learning to be good followers. Good followers are sorely needed in a country many of whose youth aspire to be leaders or they won't play.

As to format, type, and illustration, the book is a model of modern educational technic. One of the several styles of type used is aggravating to the astigmatic and presbyopic eye, but this is a minor matter to the average high school reader. One wonders if human society might not become dull if everyone succeeded in applying to the fullest extent the tolerance, understanding, wisdom, and self-control advocated herein. Like virtue, however, these are traits worth striving for, but never fully attainable. Too, heredity would doubtless preserve enough atavistic genes to spice our society with the occasional crank and misanthrope.

This book opens a new vista of hope and encouragement for the public health administrator. It is a contribution to the field of mental hygiene. It should be on the desk of every health educator.

W. P. SHEPARD

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Mister Nelson Says—Fuel oil for thirty states and 96 million persons will be restricted about a third and will be rationed. Supplementary supplies may be available for households with infants, old or sick people, but we shall have to think in terms of "discomfort zones" with a slogan "keep the home fires burning—low." At 65° artificial humidification of the air in the typical home is unnecessary. Reduced temperature is not injurious to healthy persons adequately clothed.

ANON. Health Aspects for (sic) Fuel Rationing. J.A.M.A. 120, 5:370 (Oct. 3), 1942.

Too Many Cooks—Conflicts between health and labor departments that have prevented an all-out attack on New Jersey's rapidly exacerbating industrial health situation are reported upon by a committee of the State Consumers League. The linen may not be exactly dirty but there just is a trace of that telltale gray.

ANON. Need for an Industrial Health Program in New Jersey. Med. Care (Quarterly). 2, 2:118 (Apr.), 1942.

On Forty-eight Fronts—Venereal disease control and other social hygiene activities of all our united states and some of the larger cities therein, is reported in heartening detail in three succeeding issues to produce a handy compendium that you may want for reference.

ANON. Social Hygiene in Wartime. J. Social Hyg. 23, 4 (et seq.):185 (Apr.), 1942.

When Emotional Cripples Work—One person in twenty spends part of his life in a hospital for mental disease.

One in sixteen of the selectees was rejected by draft boards because of mental or nervous defects. Many of these mental cripples find their way into industry, geared now to a fast tempo. Here, then, is a problem which raises the question: what can industry do about it? The components of a successful program are discussed in this excellent paper.

CAMERON, E. S. Mental Hygiene in Industry. Pub. Health Nurs. 34, 10:54 (Oct.), 1942.

Pellagra, Obesity, Underweight, Anemia—Malnutrition does prevail in this land of plenty. Why? Among the causes are: infections, mental strain, dietary faults, ignorance, laziness, poverty, misleading food advertising, denaturing of staple foods, overconsumption of purified sugars, waste of good foodstuffs. How can these causes be corrected? Cleanse our health education of fads and selfish commercial propaganda, and make it comprehensible to the common man, says this convincing writer. He wonders how many vitamin B pills we must consume before we nurture sufficient intelligence to take one step that he proposes.

CARLSON, A. J. Food and Fitness. Sci. Month., 55, 5:403 (Nov.), 1942. (Another provocative paper by the same author.) The Challenge of Unused Human Resources. J. Am. Dietet. A. 18, 10:647 (Oct.), 1942.

For Arctic Explorers, et al.—Should you be that one in a thousand who goes roughing it in sub-zero weather, then be warned that even in tents and igloos, a Primus stove may generate more carbon monoxide than can escape through canvas or cracks in

the snow house. Poisoning has occurred under these conditions.

IRVING, L., *et al.* Experiments on Carbon Monoxide Poisoning in Tents and Snow Houses. *J. Indust. Hyg. & Toxicol.* 24, 8:213 (Oct.), 1942.

About Minerals—Sodium, potassium, calcium, magnesium, chlorine, iodine, phosphorus, sulphur, iron, copper, manganese, cobalt, and zinc in the human body's economy is the fairly inclusive subject of this year's Harben Lectures given at the University of Toronto.

McCOLLUM, E. V. Inorganic Elements Which Present Nutritional Problems of Practical Importance. *J. Roy. Inst. Pub. Health & Hyg.* 5, 9:165 (Sept.), 1942.

Prostitution, Social Protection and the Police—Houses of prostitution and red light districts in more than 300 communities have been closed in the current wartime effort to prevent venereal infections among the armed forces. What the social protection section and the National Advisory Police Committee are doing to effect further (and still badly needed) betterment in an improving situation is recounted in this and the accompanying papers.

NESS, E. The New Offensive Along the Police Front. *J. Social Hyg.* 28, 7:365 (Oct.), 1942.

While Doctors Disagree—"Sister Kenny's treatment is superb nursing and common sense . . . early deformities are not seen in those cases under her care in the Minneapolis hospitals." (vs.) ". . . this method in time will take its place among the others offered by the field of physical therapy as having been tried but found wanting." You've guessed it: these are just two opinions voiced in a panel discussion on poliomyelitis. You will be well repaid for your reading of the whole series of papers.

SABIN, A. B., *et al.* Pathology and Pathogenesis of Human Poliomyelitis (and

four related papers). *J.A.M.A.* 120, 7:506 (Oct. 17), 1942.

Almost a Quarter Finished High School—One valuable innovation of the 1940 census was the recording of information about the number of years of schooling completed by men and women over 25 years of age, by urban-rural, nativity, color, and sex status. Such data are helpful in understanding the behavior of our people as workers, consumers, voters, and beneficiaries of our health services.

SHRYOCK, H. S. 1940 Census Data on Number of Years of School Completed. *Milbank Quart.* 20, 4:367 (Oct.), 1942.

Not Statistics But Babies, Alive or Dead—Until the middle 20's infant death rates in urban areas were higher than rural; since that time the rural rates have been greater. City rates are lowest, but towns of 2,500 to 10,000 provide the least favorable environment for infant survival, for the town rate is 9 per cent higher than in the country areas. Extension of effective public health to small towns should save a lot of infant lives, wisely concludes this study.

SOMMERS, H. J. Infant Mortality in Rural and Urban Areas. *Public Health Rep.* 57, 40:1494 (Oct. 2), 1942.

What Workers Work Upon—Diets of a thousand aircraft employees—the new rich—were studied. Very few men were eating meals that meet good dietary standards. Too few colored vegetables were included, citrus fruits were neglected (and this was a Sunkist group, please note), and too little milk was drunk.

WIEHL, D. G. Diets of a Group of Aircraft Workers in Southern California. *Milbank Quart.* 20, 4:329 (Oct.), 1942.

Nursing for Small Industries—Twenty-two visiting nurse associations

reported upon the type of part-time nursing services they render under contract with 44 different mercantile or industrial firms. The nature of various types of service is tabulated and discussed. This would seem to be a promising but very tiny beginning of an enormous job.

WIESNER, D. E. Policies in Industrial Nursing by V.N.A.'s. *Pub. Health Nurs.* 34, 10:585 (Oct.), 1942.

Preschool Toxoid Treatment—Argument is presented for a reinforcing dose of unmodified diphtheria toxoid before entering school, to be administered to children immunized in infancy. A Schick-negative condition may be expected in 97 per cent of those who are so protected.

WILKEY, J. R. Diphtheria Toxoid and the Reinforcing Dose. *Canad. Pub. Health J.* 33, 9:446 (Sept.), 1942.

ASSOCIATION NEWS

Felix Joel Underwood, M.D. President-Elect

DR. FELIX JOEL UNDERWOOD, State Health Officer of Mississippi, was chosen President-Elect of the Association at the 71st Annual Meeting in St. Louis, Mo., in October. Dr. Allen W. Freeman, Professor of Public Health Administration, Johns Hopkins University, Baltimore, Md., was inducted into office as President. Dr. John L. Rice, Consultant to the New York City Department of Health, retired as President.

Dr. Underwood was born in Nettleton, Miss. He took his M.D. degree at the University of Tennessee in 1908, and thereafter practised medicine and served as part-time Health Officer of Monroe County, Miss., and finally as Director of the Monroe County Health Department until 1920. In 1921 he became Director of the Bureau of Child Hygiene of the Mississippi State Board of Health, and in 1924 State Health Officer.

Dr. Underwood has served, or is now serving, on many boards, commissions and conferences, including the Board of Directors of the Standard Life Insurance Company, the Executive Committee of the State Board of Public Welfare, the Board of Trustees of the Mississippi State Tuberculosis Sanatorium, the White House Conference on Child Health and Protection, and the National Malaria Committee. He has served as a member of the Board of Scientific Directors of the Rockefeller Foundation, and of the Public Health Committee of the Commonwealth Fund; he is a member of the Advisory Com-

mittee of the National Organization for Public Health Nursing. The Mississippi State Medical Association, the Southern Medical Association and the Conference of State and Provincial Health Authorities have honored him with the office of President.

FELIX JOEL UNDERWOOD, M.D.

Dr. Underwood was elected to membership in the Association in 1924, and to Fellowship in 1934. Since 1941 he has been a member of the Executive Board. He is Chairman of the Conference Committee between the Conference of State and Territorial Health Officers and the A.P.H.A. Committee on Professional Education, under whose guidance the significant Merit Systems Project is being developed.

Sedgwick Memorial Medal for 1942 Awarded to Dr. C.-E. A. Winslow

THE award was made on October 27, 1942, during the Seventy-first Annual Meeting of the American Public Health Association in St. Louis, Mo., by Haven Emerson, M.D., Chairman of the Sedgwick Memorial Medal Committee. In presenting the medal, Dr. Emerson said:

"Charles-Edward Amory Winslow, friend of the poor and disadvantaged, standard bearer of Christian ideals in human relations, persistent searcher for the truth of causes and effects of human survival at ever higher levels, we greet you with an enduring affection for those very qualities of heart and mind that made the name of Sedgwick symbolic of the social application of biology.

"On the part of the committee authorized to make the award, I hand you this golden token that serves perennially to express our belief that the best that man has already done can and will be bettered by the loyal disciples of great teachers of thought and science of opinion and fact."

In accepting the award, Dr. Winslow said:

"I cannot tell you how deeply I appreciate this honor which you have conferred upon me. It means much because it comes from the American Public Health Association—the comradeship in which I have labored to the best of my ability for forty years—the brotherhood in whose achievements I have always felt a deep and a proud satisfaction. It is doubly precious because it comes by the hand of Haven Emerson whom I have honored and loved as a gallant and devoted leader in our common tasks. Above all, however,

I prize this award because it links my name for the moment with the name of one who was not only a great teacher but something much more vital and intimate. A superior in the church is known as one's 'Father in God.' To those of us who were intimately associated with him, Sedgwick was our Father in the Spirit.

"After all, the purpose of this award is not primarily to place each year a

C.-E. A. WINSLOW, DR.P.H.

crown on the brow of a more or less worthy recipient. It is to keep the laurel green on the memory of a great pioneer in American public health and, above all, a human being whose personality, whose soul, was far more signifi-

cant than any or all of his concrete achievements. There are not many in this hall who enjoyed so fully the privilege of his companionship as did Mrs. Winslow and I. We were both his pupils. We met in his laboratory. We labored by his side in the department for twelve years. We see his face and hear his voice tonight. We hope always to keep burning the torch which he lighted.

"Intellectually, Sedgwick, as a pupil of Martin, the associate of Huxley, was a child of the Victorian day—a day whose serene spaciousness, scientific reasonableness, and warm humanitarianism seems in these dark hours like some remote Golden Age of human history. Yet he had in him, too, a strong and essential mixture of the Puritan. He was never lulled into slackness by faith in automatic perfectionism. He knew that the world was a hard world and that progress comes only by ceaseless effort. He was alert to the call of duty 'stern daughter of the Voice of God.' The motive power in every hour of his life was service. He almost

never used the word; but he made the tacit assumption that the aim of every human being was to 'leave the world better and happier than he found it.' After one long and intimate talk with me he said, 'Well, Winslow, I think you can be a very useful man.' Not a rich man, not a successful man—a useful man.

"This is perhaps, more than any other, the attitude of mind that we must cultivate today. Not only in the winning of the war but in the even harder task of winning a durable peace, intelligent practical coöperation between man and man, between nation and nation, for the upbuilding of a better world is the task we must achieve.

"As recipient of the Sedgwick Medal in 1942 I stand here not in any merely personal capacity but as the representative of all of you who make up the brotherhood of public health. On your behalf, as well as on my own, I accept the challenge of Sedgwick's spirit and pledge our utmost efforts in meeting the most urgent crisis in the history of human civilization."

FELLOWS AND LIFE MEMBERS ELECTED AT ST. LOUIS ANNUAL MEETING

The Governing Council at its meetings in St. Louis, during the 71st Annual Session of the Association, upon recommendation of the Sections and the Committee on Eligibility, elected 133 new Fellows, 3 Honorary Fellows, namely, William Mowll Frazer, M.D., O.B.E., M.Sc., Medical Officer of Health of the City and Port of Liverpool, England, and Professor of Public Health at the University of Liverpool; E. R. A. Merewether, M.D., M.R.C.P., F.R.S., His Majesty's Medical Inspector of Factories, Ministry of Labor, London; and Sir John Boyd Orr, M.D., F.R.S., LL.D., Director, The Rowett Research Institute, Bucksburn, Aberdeenshire, Scotland.

Six life members of the Association were elected at the same time, namely, Muriel F. Bliss, C.P.H., Attleboro, Mass.; Marguerite F. Hall, Ph.D., Division of Hygiene and Public Health, University of Michigan; Wilton L. Halverson, M.D., Dr.P.H., Los Angeles County Health Officer, Los Angeles, Calif.; Edward A. Piszczek, M.D., Health Officer, Cook County Public Health Unit, Chicago, Ill.; David A. Van der Slice, M.D., Division of Hygiene and Public Health, University of Michigan, Ann Arbor, Mich.; and Robert G. White, M.D., Director, Division of Preventable Diseases, State Department of Health, Bismarck, N. D.

OFFICERS, 1942-1943

President, Allen W. Freeman, M.D., Baltimore, Md.

President-elect, Felix J. Underwood, M.D., Jackson, Miss.

Vice-Presidents, Alice Hamilton, M.D., Hadlyme, Conn.

Felix Hurtado, M.D., Havana, Cuba

Frederick W. Jackson, M.D., D.P.H., Winnipeg, Man.

Treasurer, Louis I. Dublin, Ph.D., New York, N. Y.

Executive Secretary, Reginald M. Atwater, M.D., New York, N. Y.

Chairman of Executive Board, Abel Wolman, Dr.Eng., Baltimore, Md.

NEW ELECTIVE MEMBERS OF THE GOVERNING COUNCIL WITH TERMS
EXPIRING IN 1945

Gaylord W. Anderson, M.D., Washington,
D. C.

Margaret G. Arnstein, R.N., New York, N. Y.

E. L. Bishop, M.D., Chattanooga, Tenn.

Walter H. Brown, M.D., San Francisco, Calif.

V. M. Ehlers, C.E., Austin, Tex.

Selskar M. Gunn, New York, N. Y.

James P. Leake, M.D., Washington, D. C.

Arthur P. Miller, C.E., New York, N. Y.

Alton S. Pope, M.D., Boston, Mass.

Huntington Williams, M.D., Baltimore, Md.

NEW MEMBERS OF THE EXECUTIVE BOARD

James A. Doull, M.D., Cleveland, Ohio—1945

Charles F. Wilinsky, M.D., Boston, Mass.—1944

Abel Wolman, Dr.Eng., Baltimore, Md.—1945

THE ST. LOUIS MEETING

ELSEWHERE in this issue an attempt is made to bring to *Journal* readers the flavor of the 71st Annual Meeting in St. Louis, October 27-30, through a stenotypist's report, only slightly edited, of the meeting's final session. This was announced under the title "Highlights of the 71st Annual Meeting," and the participants in the panel were members of the Editorial Staff and of the Editorial Board of the *American Journal of Public Health*. The panel leader was Dr. Reginald M. Atwater.

The discussions convey the scientific atmosphere and point up the many

matters with which public health workers are concerned in this war year. Because the most important feature of any meeting is the audience, we supplement the transcript of the "Highlights" session with facts and figures about the people who attended the Annual Meeting.

The total registration was 2,636. Every state in the Union was represented, many by more individuals than in any recent year. There were 38 from California, and 10 from Washington, for example. Missouri, as would be natural, stands highest numerically, with 627 registered delegates. Illinois is next

with 394, New York third with 239, and Michigan fourth with 139. Thereafter, the numbers drop, but only 6 states show less than 5 registrants each.

Mexico sent 18 delegates; Chile and Panama, 3 each; Bolivia, Colombia, Peru, Uruguay, Cuba, Costa Rica, 2 each, and Ecuador, Guatemala, Honduras, Brazil, Paraguay, and Haiti, 1 each.

Delegates from Canada numbered 32, from England 3, from Bermuda 1, from Scotland 1, and 1 delegate came from each of our own territories.

The United States Army, Navy, U. S. Public Health Service, Children's Bureau, Office of Defense Health and Welfare Services, Office of Civilian Defense, and many other federal official and national unofficial agencies were represented.

Fifteen related organizations and

conference groups met with the Association.

The Ninth Institute on Public Health Education, with a faculty of 65, enrolled 278 registrants.

Altogether there were held 176 sessions, group conferences, breakfasts, luncheons, and dinners, addressed by 397 speakers. All were well attended. The Annual Banquet brought together 778 guests.

Eighty scientific exhibit booths were occupied, lining on both sides the Promenade around Convention Hall in the Municipal Auditorium. These, and the 79 technical exhibit booths in Convention Hall itself, presented perhaps the most impressive exposition the Association has sponsored to date.

Resolutions of appreciation to the Local Committee and to its Chairman, Dr. Joseph F. Bredeck, were adopted.

RESOLUTIONS

THE following Resolutions were unanimously adopted by the Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

1. APPRECIATION TO DR. BREDECK AND THE LOCAL COMMITTEE

RESOLVED that the American Public Health Association expresses its grateful appreciation to the St. Louis Local Committee and to the agencies and individuals represented thereon.

RESOLVED that the thanks of the officers and members be extended to Dr. Joseph F. Bredeck, Health Commissioner of St. Louis and Chairman of the Local Committee, and to the chairman and members of the several subcommittees, whose services have contributed so markedly to its success.

2. APPRECIATION TO THE ST. LOUIS HEALTH DIVISION

RESOLVED that the American Public Health Association expresses its thanks to the St. Louis Health Division and its personnel for their valuable assistance in the conduct of the Seventy-first Annual Meeting.

3. APPRECIATION TO THE LADIES' ENTERTAINMENT COMMITTEE

RESOLVED that the American Public Health Association expresses its appreciation to the Ladies' Entertainment Committee for their gracious hospitality and their many courtesies extended to the delegates, and be it further

RESOLVED that our thanks be extended to Mrs. Martin J. Glaser, Chairman, and Mrs. Joseph C. Peden, Vice-Chairman of the Ladies' Entertainment Committee for their thoughtfulness in our behalf.

4. APPRECIATION TO THE ST. LOUIS CONVENTION BUREAU AND TO THE ST. LOUIS AUDITORIUM

RESOLVED that the American Public Health Association acknowledges its gratitude to the St. Louis Visitors' Convention Bureau and to the Municipal Auditorium and their personnel for their splendid cooperation in

making such excellent facilities available for the Seventy-first Annual Meeting.

5. APPRECIATION TO THE PRESS

RESOLVED that the American Public Health Association acknowledges its indebtedness to the press, national, state, and local, for its service in connection with the Seventy-first Annual Meeting.

6. APPRECIATION TO EXHIBITORS

RESOLVED that the American Public Health Association expresses its grateful appreciation to the friends and coöperators who have presented at its Seventy-first Annual Meeting the excellent exhibits, both scientific and technical, which are of such great interest and value to the public health profession.

7. THANKS TO HOTELS

RESOLVED that the American Public Health Association expresses its appreciation to the hotels in St. Louis for their assistance in the conduct of the Seventy-first Annual Meeting.

8. WARTIME MATERNAL AND CHILD HEALTH

WHEREAS the war has created many conditions that endanger the lives and well-being of infants and children, including particularly life in crowded, unfit dwellings and communities, lack or inadequacy of child health services and medical and hospital care for sick children, crowded maternity wards and dangerously crowded nurseries for new-born infants, and inadequate maternity care, resulting in too early discharge of women and their infants from hospital, and

WHEREAS in many places, as the population has grown rapidly because of war industries or military establishments, the provision of health and medical service has not kept pace, and

WHEREAS many thousands of women are being drawn into war production industries or into work on farms or into domestic service, including mothers of young children, with the resulting need for special health and welfare services for children, and

WHEREAS boys and girls of secondary school age are seeking work in factories or farms, in many cases work that taxes their physical strength and endurance and affects their emotional and social stability, and

WHEREAS the changes in family and com-

munity life created by the war, especially the absence of the father from the home, are causing many additional emotional and social problems among children and youth with resultant increase in delinquency, and

WHEREAS the morale of the men in the armed forces depends in no small degree on the knowledge of the health and well-being of their wives and children at home, therefore be it

RESOLVED that the American Public Health Association go on record as urging: (1) that immediate attention be given by appropriate public and private health agencies to the expansion in all practical ways of programs of maternity care and health service and medical care for children, especially those in areas affected by war industries and military establishments; (2) that attention be directed to the health and medical services, including mental hygiene, required for children of working mothers and for adolescents and youth who are about to leave school for work or are already employed in war industries, on farms or in other essential service trades; and (3) that special attention be given to making available adequate provision for maternity care of the wives of men in the military services and for health and medical service for their children.

9. ON MERIT SYSTEMS

WHEREAS the indefinite professional status and insecure tenure of employment of public health personnel in many health jurisdictions of the United States has been a serious handicap to the recruitment and retention of qualified personnel, and

WHEREAS, notwithstanding the serious obstacles that arise from the war emergency, substantial progress has been made toward acceptable systems of personnel administration on a merit basis, therefore be it

RESOLVED that the American Public Health Association reaffirm its faith in a properly conceived and administered system of personnel administration and that we urge the appropriate federal, state, and local health officials to perfect and extend those systems now in existence and in the course of development; and be it therefore

RESOLVED that professional qualifications be upheld for those persons seeking permanent status and that, when the emergency becomes so acute that inadequately trained personnel must be employed, such personnel be placed on temporary appointment in special grades below those which the position would normally rate.

10. LOCAL HEALTH UNITS

WHEREAS, the immediate emergencies of war-time and the continuing necessities of a nation at peace require health protection for all within our boundaries, and

WHEREAS, the most effective state and national health services can be provided only when all communities have accepted the responsibility of applying the science and art of preventive medicine as a permanent function of local civil government, therefore be it

RESOLVED that all practical measures be taken by the officers and the Executive Board of the American Public Health Association to promote the creation and adequate support of health services by local government throughout the United States and Canada to the end that no community of our people shall be left without the public care which can be best supplied only through full-time trained medical officers of health with sufficient numbers of qualified assistant personnel, and be it further

RESOLVED, that collaboration with other professional, official and voluntary organizations be sought to obtain total coverage of these nations by local health units at the earliest practicable date.

11. CONTINUED TRAINING OF PUBLIC HEALTH PERSONNEL

WHEREAS the present emergency puts unprecedented demands upon public health personnel, and

WHEREAS the war period is presenting serious and numerous problems requiring exceptionally well trained professional public health personnel, and

WHEREAS it would be reasonable to expect

RESOLUTION FROM LATIN AMERICAN
SANITARY ENGINEERS AT
ANNUAL MEETING

At the banquet session of the 71st Annual Meeting of the Association held in St. Louis, Mr. Luis Pachon Rojas, Sanitary Engineer of the Ministry of Health and Labor of the Republic of Colombia, and on behalf of all the Latin American sanitary engineers in attendance at St. Louis, presented the following resolutions:

"The Latin American Sanitary Engineers attending the 71st Annual Meeting of the

that this situation will be aggravated during the post-war period, now therefore be it

RESOLVED that all health agencies be urged to make every possible effort to continue the professional training of all types of personnel, utilizing to the fullest extent funds available from all sources.

12. NUTRITION

WHEREAS the importance of upholding health standards has assumed new significance during the war, and

WHEREAS we have come to a new realization of the importance of adequate diet, therefore be it

RESOLVED that it is an important function of any health agency, including the schools, to take every step toward providing the adult as well as the child population with a properly balanced diet, taking full advantage of the systems available through the U. S. Department of Agriculture in the establishment of suitable school lunch and school milk programs.

13. MORBIDITY NURSING

WHEREAS the dislocation of considerable segments of the population and the dislocation of physicians, nurses, and dentists emphasizes the desirability of extending nursing care to the sick in their homes, and

WHEREAS the accomplishment of this objective in many areas may now be possible through the coördination of all public health nursing services, including the full utilization of auxiliary services, therefore be it

RESOLVED that the American Public Health Association endorse the principle that nursing care of the sick in their homes should be an integral part of a community public health nursing program.

American Public Health Association in St. Louis, Mo., have unanimously approved the following motions: 1st: To express our deepest gratitude to the Pan American Sanitary Bureau for the kind invitation to attend the 71st Convention of the American Public Health Association and also for the timely opportunity to meet most of the outstanding men engaged in public health activities in this country. 2nd: To voice our sincere appreciation to the American Public Health Association for the hearty welcome that was extended to us on this occasion which demonstrates the community of ideals that exists among those who are devoting their efforts to the welfare of the people of this hemisphere. 3rd: To thank the Conference of

State Sanitary Engineers and the Conference of Municipal Public Health Engineers for their generous gesture in extending to us the privilege and high honors of membership in their organization and to assure them our fullest collaboration in the solution of the inter-American sanitary engineering problems and the complete support of our group."

A sustained round of applause greeted the presentation of these resolutions and a rising vote of appreciation was accorded the visitors at the suggestion of Harry S. Mustard, M.D., the presiding officer.

DELEGATION FROM MEXICO AT ST. LOUIS A.P.H.A. MEETING

The delegation from Mexico at the 71st Annual Meeting of the Association in St. Louis in October was headed by Dr. Angel de la Garza Brito, Dean of the School of Hygiene and Public Health in Mexico City. Also in attendance were Dr. Manuel Gonzalez Rivera, the Supervisor General and the Chief of the technical staff of the Federal Department of Health, Mexico City.

From the Bureau of Venereal Diseases were Dr. Enrique Villela, Chief of the Federal Bureau. Dr. Juan L. Soto, the Director of the Federal District Bureau, and Dr. Samuel Villalobos. Carlos Lopez Fuentes was in attendance, representing the public health engineers

from the Federal Bureau of Sanitary Engineering.

LATIN AMERICAN COUNTRIES REPRESENTED AT A.P.H.A. MEETING

Among those in attendance at the 71st Annual Meeting in St. Louis were sanitary engineers from several Latin American countries, present as guests of the Pan American Sanitary Bureau. Included in this list were the following sanitary engineers from the countries indicated:

F. A. Aragon, Costa Rica
Angel Balcarcel, Guatemala
Julio Caballero, Chile
Ruperto Casanueva, Chile
Felipe de Santiago, Uruguay
Gerald Ewald, Haiti
Carlos Lopez Fuentes, Mexico
Carlos Guardia, Panama
Julio Jauregui, Bolivia
Luis Mantilla, Peru
Renan Mendez, Costa Rica
Sergio Palacios, Honduras
Louis Pachon Rojas, Colombia

Accompanying the visitors were the following officials connected with the Pan American Sanitary Bureau.

Dr. E. C. Ernst, *Assistant Director*
J. Corigliano, *Fiscal Officer*
E. D. Hopkins, *Sanitary Engineer*
W. N. Dashiell, *Sanitary Engineer*
Dr. A. A. Moll, *Secretary*
Dr. John R. Murdock, *Traveling Representative*.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Frank M. Baker, M.D., East Side Health District, East St. Louis, Ill., District Asst. Epidemiologist, State Public Health Dept.
Caroline H. Callison, M.D., Coosa County Health Officer, Rockford, Ala.
H. L. Chambers, M.D., City Hall, Lawrence, Kan., Director, Douglas County Health Unit
Everett H. Ellinwood, M.D., P. O. Box E, Snow Hill, N. C., Epidemiologist and Health Officer, State Board of Health

Floyd W. Highfill, M.D., Box 308, Duncan, Okla., Director, Stephens County Health Dept., State Health Dept.
S. H. Kash, M.D., 4523 S. Sheridan Drive, Cudahy, Wis., Health Officer
Leslie W. Knott, M.D., M.P.H., 216½ E. Monroe St., Springfield, Ill., Asst. Chief, Div. of Local Health Admin., State Dept. of Public Health
Louis G. Llewelyn, M.D., Deputy State Health Officer, Pocomoke City, Md.

James L. Mudd, M.D., 634 N. Grand Blvd.,
St. Louis, Mo., Tuberculosis Controller,
Health Division, City of St. Louis

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

POSITIONS AVAILABLE

U. S. CIVIL SERVICE COMMISSION. Public Health Nursing Consultants, 5 grades. See November *American Journal of Public Health*, or write U. S. Public Health Service, Washington, D. C.

Merit System Council, Oregon State Board of Health and Crippled Children's Division, has announced merit examinations in practically all public health fields. See November *American Journal of Public Health*, or write H. J. Sears, Merit System Supervisor, P. O. Box 88, Portland, Ore.

Indiana State Personnel Division announces that applications may be filed for positions in orthopedic nursing, medical positions (5 classes), and local public health director. See November *American Journal of Public Health*, or write Indiana State Personnel Division, 141 South Meridian Street, Indianapolis, Ind.

Physician, man or woman, as director of Division of Maternal, Child and School Hygiene in southern city department of health. Woman physician with pediatric training preferred, public health experience not essential. To operate prenatal, infant and preschool clinics and promote school health program. Salary commensurate with ability and qualifications of applicant. Apply Box J, Employment Service, A.P.H.A.

Southern state department of health seeks several obstetric and pediatric consultants, requiring a minimum of a year's residency in a specialty, immunity to draft and preferably training in public health. Men and women are eligible. Salary \$300 per month plus travel. Apply Box C, Employment Service, A.P.H.A.

Public Health Engineer and director of Division of Sanitation of a city and county health unit; population 145,000 in the Midwest. Salary \$3,180 and travel allowance. Box E, Employment Service, A.P.H.A.

The Flint Civil Service Commission will consider applications for Executive Health Officer of the Flint Department of Health. Applicants must be medical graduates with a valid license to practise medicine in Michigan or eligibility for such license; also must have practised

medicine and surgery for five or more years and had considerable experience in public health work. There will be no written test, qualifications being judged solely from review of experience, education and training and an oral examination. Present incumbent is on military leave of absence under circumstances which will probably extend for a period of five years. Staff consists of over fifty professional and technically trained employees. Probable salary \$5,400. Inquiries should be directed to Foster B. Roser, Director, Flint Civil Service Commission, City Hall, Flint, Mich.

The Alaska Merit System announces the following positions:

Position	Salary per month
Assistant Commissioner of Health	\$500 to \$625
Maternal and Child Health Director	380 to 455
Director, Division of Public Health Engineering	290 to 335
Sanitarian, Senior Grade . .	215 to 245
Sanitarian	185 to 215
Bacteriologist, Senior Grade	290 to 335
Bacteriologist, Junior Grade	215 to 245
Laboratory Technician . . .	185 to 215
Public Health Nurse	185 to 215

Appointments are being made on a provisional basis with examinations following when the staff is more adequately completed.

Apply to W. H. Matthews, Jr., Alaska Merit System, Box 201, Juneau, Alaska.

MEDICAL OFFICERS NEEDED—TENNESSEE VALLEY AUTHORITY

The Tennessee Valley Authority is in urgent need of medical officers who are not eligible for military service and who are willing to accept assignments to war industrial activities (construction, manufacture of war chemicals and manufacture of hydroelectric power) as their participation in the all out war effort. Responsibilities include physical examinations, industrial hygiene, care of injuries, med-

ical care to families in remote construction areas and general public health responsibilities in construction camps and villages.

Salary ranges from \$3,200 to \$4,200 per annum with opportunity for promotion.

For further information write to Dr. E. L. Bishop, Director of Health, Tennessee Valley Authority, Chattanooga, Tenn., or to the Personnel Department, Tennessee Valley Authority, Knoxville, Tenn.

FOR OTHER POSITIONS AVAILABLE SEE NOVEMBER AMERICAN JOURNAL OF PUBLIC HEALTH OR WRITE EMPLOYMENT SERVICE, AMERICAN PUBLIC HEALTH ASSOCIATION, 1790 BROADWAY, NEW YORK, N. Y.

POSITIONS WANTED

In view of the current active demand for trained and experienced persons in public health it is suggested that prospective employers communicate directly with the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y., for up-to-date lists of applicants.

Advertisement

BACTERIOLOGIST—B.S., M.D., D.Sc. degrees, with majors in bacteriology; certificate in public health, eastern university; several years' teaching experience, including professorship in bacteriology and pathology; able lecturer; now interested in public health appointment. For full details, write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago.

NEWS FROM THE FIELD

DRAFT INTERIM REPORT

Medical Planning Commission

A summary of the *Draft Interim Report* of the Medical Planning Commission (*British Medical Journal*, June 20, 1942) has been prepared for the *Journal* by Dr. Michael M. Davis, Chairman of the Committee on Research in Medical Economics, Inc.

To both physicians and laymen it is significant that a body of seventy physicians, which was appointed by the British Medical Association and which has worked for more than a year preparing this preliminary report, recommends a substantial reorganization of medical practice and closer relations of preventive and curative services. The *Report* has recently been considered and its major recommendations approved in principle by the Representative Assembly of the British Medical Association. It is now the subject of discussion in all local branches of the Association and will be revised by the Commission in the near future for official presentation to the profession, the Government, and the British public.

A small minority of the Commission favored a whole-time salaried medical service in which medicine would be put on a basis parallel to education as a function of the state. The majority of the Commission, however, recommended the extension of the national health insurance system (now covering little more than general practitioner service for employed persons) to include the services of specialists, and to cover the dependents of employed persons and other groups, or about 90 per cent of the whole population. This is substantially what the British Medical Association has itself advocated for more than a decade.

Of special interest to public health officers are the recommendations for the organization of medical practice:

"... There is general agreement that co-operation amongst individual general practitioners in a locality is essential to efficient practice under modern conditions, though views vary on the form of the co-operation. The principle of the organization of general practice on a group or co-operative basis is widely approved. A convenient term for the focal point of co-operation is "health centre."

The organization and relationships of the proposed health center system are described in detail. The center would include a much wider scope of work than the district health centers which have been established by American health departments in a number of cities. The medical practice of the locality would be carried on within and from these centers, and from the hospitals with which they would be associated. Each center would be staffed by the local practitioners and affiliated specialists, with an organization corresponding to that of a well planned clinic.

The Commission is practically unanimous in recommending that the voluntary and governmental hospitals should be brought within a single framework of local and regional organization, preserving some autonomy in the management of individual institutions, but coördinating their functions and staffs under a general plan. It will be recalled that, in Britain, the medical officer of health is usually in charge of the local governmental hospital system as well as of the preventive services. Preventive and curative work for industrial employees is touched upon by the Commission and is to be the subject of a subsequent report.

"In view of the fact that the full adoption of the plan may be delayed for several reasons" ... the Commission

suggests three steps for "immediate post war application," namely, the extension of the health insurance system, experimental health centers in some areas, and the creation of regional hospital councils with executive or advisory functions.

NEW OFFICERS OF THE AMERICAN SCHOOL HEALTH ASSOCIATION

The following new officers were elected at the business session of the American School Health Association, which was held in St. Louis:

President—C. E. Turner, Dr.P.H., Cambridge, Mass.

President-Elect—G. Morley Sellery, M.D., Los Angeles, Calif.

Executive Secretary-Treasurer—A. O. DeWeese, M.D., Kent, Ohio

Vice-Presidents—Arthur E. Turner, M.D., Chicago, Ill.; Gertrude Cromwell, R.N., Des Moines, Iowa.

NEW OFFICERS OF THE COLORADO PUBLIC HEALTH ASSOCIATION

At its Annual Meeting held in September, the Colorado Public Health Association elected the following new officers to serve for the forthcoming year.

President—John H. Fountain, M.D., Greeley, Colo.

Vice-President—Edna Burke, R.N., Denver Colo.

Secretary—Evelyn Horton, R.N., Denver, Colo.

Treasurer—Virginia Adkins, R.N., Englewood, Colo.

COURSE IN INDUSTRIAL MEDICINE ANNOUNCED BY NEW YORK POST-GRADUATE MEDICAL SCHOOL

The Director of the New York Post-Graduate Medical School, New York City, has announced a course on Industrial Medicine for five days, January 11 to 15, 1943, under the direction of Harry J. Johnson, M.D., of the Department of Medicine, assisted by Franklin Carter, M.D., Medical Director, *New York Times*, Walter Dannreuther, M.D., Professor of Clinical Gynecology; Fred B. Flinn, M.D., As-

sociate Professor of Industrial Hygiene; Wilbur Duryea, M.D., Director Vascular Disease Clinic; George Ornstein, M.D., Director Seaview Sanatorium; Henry H. Ritter, M.D., Director Department of Traumatic Surgery; William Irish, M.D., Director Orthopedic Surgery; Charles Poindexter, M.D., Director Department of Cardiology, and Maurice Bruger, M.D., Director of Pathological Chemistry.

The course is planned as an intensive review in industrial medicine and is planned to give basic knowledge of the organization as well as instruction in the administration of an industrial medical department. Lectures and demonstrations will include dust hazards, lead and metal poisonings, industrial dermatoses, the problem of women in industry, industrial absenteeism, prevention of accidents and safety measures.

"COMMUNITY ORGANIZATION FOR HEALTH EDUCATION" AVAILABLE

It will be recalled that a Committee of the Public Health Education Section and the Health Officers Section of the American Public Health Association reported in 1941 under the title of Community Organization for Health Education. The purpose was to present significant experiences in community organization for health education which may be helpful to health departments, school systems, and private agencies. Twelve patterns of community organization are described as examples.

This report was prepared and distributed under a grant of the Charles H. Hood Dairy Foundation of Boston, Mass. A large edition was completely exhausted and a second edition has now been made available through the courtesy of the Charles H. Hood Dairy Foundation which will shortly be available at the same cost of 9 cents per single copy postpaid, or c.o.d. if ordered in quantity, charges being only the wrapping costs.

NUTRITION FOUNDATION, INC., NEW
YORK, MAKES ADDITIONAL
RESEARCH GRANTS

According to announcement by the Nutrition Foundation in November, 18 additional grants in aid totaling \$46,600 were made, bringing the total of grants to 54 during the current year and including 33 colleges, universities, and medical centers. The present grants include projects at Northwestern University, University of Illinois, Notre Dame, and University of Wisconsin as well as the Universities of Virginia, Arkansas, Stanford, Rochester, Harvard, Cornell, Southern California, California, and the Alabama Polytechnic Institute.

Among the types of new studies supported by the Foundation are the isolation of unstable food factors, protein utilization during partial starvation, studies of radioactive iron, protection of the teeth afforded by specific nutrients, nutritive protection against infection, nutritive value of low-cost vegetables and nutritive protection of the blood vessels.

Contributions to the food industry to support basic research for the next five years were announced at \$1,100,000. Charles Glen King, Ph.D., New York, is Scientific Director of the Foundation.

DR. WILE WILL CONDUCT TRAINING
COURSE IN SYPHILIS

Udo J. Wile, M.D., Professor of Dermatology and Syphilology at the University of Michigan, Ann Arbor, has been commissioned Medical Director in the U. S. Public Health Service Reserve and has been assigned to active duty in the Division of Venereal Disease Control. According to the announcement, Dr. Wile will conduct a survey of new methods for the intensive treatment of syphilis and will supervise the quarantine hospitals which the Public Health Service and the states are developing in critical war areas. These hospitals are for the treatment of pros-

titutes and recalcitrant persons who are infected with syphilis and who are capable of spreading the disease. It was announced that the first class of physicians, nurses and record analysts would assemble in November at Ann Arbor for an intensive training course under Dr. Wile's direction.

NEW YORK STATE DEPARTMENT OF
HEALTH PERSONNEL ENTER
MILITARY SERVICE

Members of the Professional Staff of the New York State Department of Health who have entered military service between May 16 and October 22, 1942:

Josephine Cunningham, Junior Statistician,
WAVES

NEW YORK STATE DEPARTMENT
PERSONNEL

The U. S. Public Health Service has loaned the New York State Department of Health two physicians, Dr. Edward T. Bloomquist, assigned to the Buffalo District Office, and Dr. Harry J. Schweigert, assigned to Albany.

Health of Toledo, Ohio, and has accepted an appointment as Assistant Medical Director of the National Foundation for Infantile Paralysis, New York, N. Y.

FRANK E. McCORD, M.D., formerly of Topeka, Ill., has been appointed in charge of the special wartime county health department established for Morgan County, in Jacksonville.

SUMNER M. MILLER, M.D.,* of Peoria, Ill., has been appointed Defense Zone Health Officer for Peoria County.

JAMES A. OLSON, M.D.,† of Flint, Mich., Director of the Mott Foundation Children's Center and Director of Health for the Flint Public Schools, has been appointed Acting Executive Health Officer of Flint.

CHESTER L. PUTNAM, M.D., M.P.H.,‡ of Manchester, Ia., has been appointed Director of Local Health Services for the Iowa State Department of Health, effective September 1, succeeding the late MARVIN F. HAYGOOD, M.D.,‡ of Des Moines.

C. A. SELBY, M.D., of North Platte, Nebr., has been appointed by Governor Dwight Griswold of Nebraska as State Director of Health. He is a Veteran of the Medical Corps of World War I; Past President of the State Medical Association, and a Fellow of the American Medical Association. He has been active in state and civic matters relating to public health. He succeeds A. L. MILLER, M.D.,‡ who was elected to the U. S. Congress in the recent election in Nebraska, to represent the 4th District.

RAYMOND G. TUCK, M.D., of Royal Oak, Mich., District Health Officer in Southern Oakland County, has been appointed Health Officer of Hazel Park; he will continue to serve as District Health Director.

JOHN P. WALSH, M.D.,‡ of Greenview,

Ill., has been appointed in charge of the special wartime county health department established for DuPage County, in Wheaton.

Eastern States

FREDERICK EBERSON, PH.D., M.D.,* resigned July 31 from his position of Medical and Research Director, National Drug Company, Philadelphia, Pa., to become Pathologist, Chief of Laboratory Service, U. S. Veterans Administration Facility, Pittsburgh, Pa. He was formerly Pathologist and Director of Laboratories, Gallinger Hospital, Washington, D. C.

LEONARD PARENTE, M.D., M.P.H.,‡ has been appointed as Medical Director and Adviser for the Connecticut State Department of Public Welfare. Dr. Parente started work in this department on September 1, 1942, and his duties will be those of organizing and administering the State Medical Care Program for the Public Welfare Department of Connecticut.

JOSEPH A. RANDAZZO, M.D.,‡ has been commissioned as a Passed Assistant Surgeon in the Reserve of the U. S. Public Health Service and has been assigned to the Division of Industrial Hygiene in the Connecticut State Department of Health, Hartford. Dr. Randazzo formerly resided in Bath, Maine.

ALEXANDER H. STEWART, M.D.,‡ of Harrisburg, Pa., Acting Secretary of the State Board of Health since 1941, and Deputy Secretary from 1939 to 1941, has been appointed Secretary.

Southern States

JAMES H. ASHCRAFT, M.D., of Reform, Ala., has been appointed Health Officer of Fayette and Pickens Counties.

DORIS L. A. BALDRIDGE, M.D., of Conway, Ark., has been appointed Health Director of Faulkner County.

* Fellow A.P.H.A.

† Member A.P.H.A.

CHARLES B. CRITTENDEN, M.D.,* of Louisville, Ky., resigned on July 2 as Director of the Division of Maternal and Child Welfare of the Kentucky State Health Department, due to ill health. ALICE D. CHENOWETH, M.D., formerly of Rosemont, Pa., has been named to succeed Dr. Crittenden.

ARTHUR C. CURTIS, M.D., of State Sanatorium, Ark., has been appointed Director of the Division of Tuberculosis Control of the Arkansas State Board of Health.

ALBERT S. DIX, M.D.,† of Opelika, Ala., has been appointed Director of Communicable Disease Control of the Mobile City and County Health Unit, succeeding ISAAC C. SUMNER, M.D.

HOWARD W. ENNES, JR., A.B.,† formerly in charge of venereal disease education for the U. S. Public Health Service, Washington, D. C., is now on duty with the Division of Preventive Medicine, Bureau of Medicine and Surgery of the Navy, as an Ensign H-V(S), USNR. He has been replaced in the U. S. Public Health Service by JUDSON HARDY.

GEORGE SELLERS GRAHAM, JR., M.D., of Birmingham, Ala., has been placed in charge of the health unit in Green County.

EDWIN N. HALLER, M.D., of Mobile, Ala., has been appointed Health Officer for DeKalb County.

HUGH C. HENRY, M.D., of Richmond, Va., Director of State Hospitals, has been appointed Commissioner of Mental Hygiene and Hospitals, a newly created position provided in the state government reorganization act, effective July 1.

EDWARD M. HOLMES, JR., M.D., M.P.H.,* for several years Director of the Division of Venereal Disease Control of the Virginia State Department of Health, Richmond, has been

assigned as Venereal Disease Control Officer at Randolph Field, Tex. WALLACE E. BAKER, M.D., of Petersburg, assistant to Dr. Holmes, has been named Acting Director of the Division of Venereal Disease Control for the duration.

WILLIAM R. KELSAY, M.D.,† of Monticello, Ky., has been named Health Officer for Clinton and Cumberland Counties in addition to Wayne County. He succeeds PAUL D. MOORE, M.D., of Albany, who has been transferred to Casey County, where he succeeds JAMES T. DUNCAN, M.D.,† formerly of Columbia who has gone to Charleston, W. Va.

ALEX C. McDUGAL, M.D., of Savannah, Tenn., is the new Health Officer of Marengo County.

JAMES O. NALL, M.D.,† of Marion, Ky., has resigned as Health Officer of Livingston County to accept a District appointment in Crittenden, Caldwell, and Lyon Counties. He has also resigned as secretary of the Livingston County Medical Society. The health unit has been combined with the one in Marshall County, with SAMUEL L. HENSON, M.D., of Benton, as full-time Health Officer.

ANTHONY P. RUBINO, M.D., formerly of Key West, Fla., of the U. S. Public Health Service, has been appointed Medical Officer in Charge of the United States Marine Hospital, Memphis, Tenn. He succeeds EDWIN H. CARNES, M.D., who was transferred to Alaska. Dr. Rubino has been a member of the Public Health Service since 1926.

JACOB LELAND TANNER, M.D., of Henderson, Ky., has been appointed Health Officer of Washington County.

DONALD B. THURBER, M.D., of Carlisle, Ky., has been appointed Director of the Tri County Health District consisting of Trimble, Carroll, and Gallatin Counties.

WALTER E. WILKINS, M.D., of Raleigh,

* Fellow A.P.H.A.
† Member A.P.H.A.

N. C., Director of the Division of School Health Service for the North Carolina State Board of Health, has been made Consultant in Nutrition to the Office of Defense Health and Welfare Services in Washington.

Western States

LUNSFORD D. FRICKS, M.D., of Seattle, Wash., has been appointed Health Officer of the Helena and Lewis and Clark Counties Health Unit, succeeding LEO F. HALL, M.D., of Helena, who has resigned on account of ill health.

WILLIAM L. JACKSON, M.D., of Burlington, Wash., has been named Health Officer of Skagit, to succeed WILLIAM V. KING, M.D., Jr.

GUY W. KENNICOTT, M.D., has resigned as Health Officer of Chehalis, Wash.

PHILIP D. KEICHUM, M.D., Health

Officer of Laramie County, was recently appointed Health Officer of Cheyenne, Wyo., succeeding WALTER S. KOTAS, M.D.,† who entered Army service.

DORSEY S. LENZ, M.D., formerly of Edgerton, Wyo., has been appointed Health Officer of Campbell County.

EMIL E. PALMQUIST, M.D.,† of Port Angeles, Wash., Health Officer of Clallam County-City Health Unit, was elected the President of the Washington State Public Health Association at its recent annual meeting.

DEATHS

DR. HORTON CASPARIS, of Nashville, Tenn., died suddenly during the week of November 8, at the age of 51.

S. S. GOLDWATER, M.D.,* formerly Commissioner of Hospitals of the City of New York, died October 22, at the age of 69.

Index of Volume 32, 1942

How to Use the INDEX

This is an Index to all the reading matter in the JOURNAL. It is essentially a title and author Index, although occasional subject headings are provided.

Articles, committee reports, and editorials are listed alphabetically according to the key words in the title, with many cross-references.

Editorials are indexed under "Editorials" as well as alphabetically under the key words in the title.

News notes and fillers are indexed under "News from the Field." This section should be searched as supplemental to the title index.

Matters pertaining to the Association are indexed under "American Public Health Association" and "Year Book."

Book reviews are indexed under "Books and Reports."

Obituaries are indexed under "Death Notices."
